The diagnosis of any injury to the cervical vertebrae depends on the history of injury, on symptoms and signs, and on adequate roentgenographic study. Pain is a predominating feature, usually more marked in fracture than in uncomplicated dislocation. Disability is usually marked. The patient guards his neck from any movement and may hold his head in his hands. Deformity will be present if displacement has occurred, but it naturally will be absent in undisplaced fractures. If the displacement is due to a unilateral dislocation, the head will probably be tilted to the side of the lesion but the chin turned away from it. If the displacement is bilateral, the head will be flexed and possibly projected forward. If the dislocation is high, the projecting vertebra may be felt in the posterior pharyngeal wall. Tenderness may be well localized over the injured vertebra, and a deformity of the vertebral column may be palpable. The examination should, of course, include a careful estimate of neurologic findings for cord or nerve root damage.

Roentgenograms are essential to determine, if possible, the presence of fractures that cannot be proved in any other way. Lateral views must be taken as well as anteroposterior views, and a view of the odontoid through the open mouth is strongly urged in every case of suspected injury to the cervical vertebrae. To allow a patient to walk around with an unprotected crack through his odontoid process is a little like allowing him to carry a ticking time bomb in his pocket.

The treatment of these cases, as in any case of fracture or dislocation, should begin at the time and at the place of injury. There are few, if any, conditions in which first aid or immediate treatment is more important. The patient should be transported on his back with his head and neck held steady between

From the Fracture Service of the Department of Surgery, Presbyterian Hospital and Columbia University

*Dr. Stimson sailed last August to serve one year with the Emergency Medical Service of the British Ministry of Health. Word has just been received that Dr. Stimson has been made a Major in the Royal Army Medical Corps (British) and has been assigned to the Military Hospital in Shenley, Hertfordshire.

sand bags, or preferably between the hands of a responsible person. Mild traction on the head should be maintained, if possible. Until the diagnosis is established, the patient should not be allowed to sit up or stand. Cases of sudden death have been reported which were caused by unguarded flexion of the head. Brookes states that "these injuries demand more prompt attention than an acute abdominal condition."¹

After the diagnosis has been reached, treatment should immediately be instituted. Correction of any existing deformity is the first consideration. Any hope of regaining cord integrity, if this has been damaged, lies primarily in removing the mechanical pressure of the displaced bone. Reduction can be accomplished by manipulation, by traction, or by open operation. The Walton maneuver of retrolateral flexion with rotation, described in 1893,² has proved satisfactory in certain cases in the hands of skilled operators. Taylor,³ in 1924, described a somewhat simpler procedure, consisting of strong traction by means of a halter around the patient's occiput and chin and around the operator's waist, which leaves the operator's hands free for any necessary manipulation. Both procedures should be done under anesthesia and checked by roentgenograms. A plaster cuirass should be applied immediately to prevent redislocation.

Because of the potential dangers involved in manipulations, reduction by prolonged traction has been advocated. A simple head halter, with a pulley and weight at the head of the bed, has the disadvantage of pressure on chin and occiput and considerable discomfort to the patient. The grooved air mattress, described by Stookey,⁴ provides traction by the weight of the head and is of particular comfort for the paralyzed patient. Nicholson⁵ has worked out a similar method by the use of three ordinary mattresses, also utilizing the weight of the head. Where a stronger force is desired, skeletal traction has definite advantages, allowing more accurate control of position and yet greater freedom for the patient.⁶ The traction may be exerted either through ice tongs carefully inserted into the skull, as described by Crutchfield⁷ and others, or by wire loops passed through drill holes in the skull, as described by Cone and Turner.⁸ Whichever method is used, adequate immobilization is essential after reduction has been accomplished.

Certain cases are encountered, however, in which reduction by any of the above-de-

scribed methods is unsuccessful or cannot be maintained, and operation must be resorted to. Fusion by the Hibbs method or by grafts, as described by Cone and Turner, has been successful, especially in cases with long-standing deformities. Wiring of the spinous processes has been found of value in certain instances.

On the Fracture Service of the Presbyterian Hospital we have had relatively little experience with the more serious injuries to the cervical vertebrae for two reasons: First, we have no ambulance service and, second, any patient with damage to cord or nerve roots goes to the Neurological Institute. Therefore, our series of cases of fractures and dislocations is small. We have seen 20 in the past twelve years. Of these, 4 showed undisplaced fractures requiring immobilization only; 8 had fracture dislocations reduced by head halter traction or by the Stookey mattress; 3 were unsuccessfully treated by traction and required manipulation under anesthesia for complete reduction; 2 were fused and 1 other was sent to another hospital for fusion, all relatively late cases; 1 unsuccessfully treated by traction and by manipulation because of a fractured articular facet, refused operation; and, finally, 1 had a fracture dislocation of six years standing, for which we did little except apply a leather collar. That is not an imposing list or one from which conclusions can be drawn. However, among them are 3 cases of sufficient interest to warrant a brief description.

Case Reports

Case 1.—A man, aged 26, was seen half an hour after he had been injured in an overturned car. He complained of pain and stiffness of the neck. Motions of the cervical region were painful and motions to the right were limited. No neurologic findings were present. Roentgenograms showed a complete forward dislocation of the third cervical vertebra on the right with a fracture just beneath the interarticular facet across the pedicle, the fragment being carried forward with the displaced vertebra. Head halter traction with 15 pounds weight for forty-eight hours produced no change; nor did two attempts at reduction under general anesthesia help. Operative interference was advised but refused by the patient; therefore, a plaster helmet and cuirass was applied. This was replaced in six weeks by a leather collar, which he wore for nearly ten months. We followed this man for seven years. He was able to carry on office work but had a thirty-degree limitation of all neck motions without pain. He developed an area of anesthesia over his right

shoulder extending downward and forward from the outer end of the clavicle which persisted unchanged for seven years.

Case 2.—A woman, aged 38, was injured in an automobile accident in the South four weeks before her admission to the Fracture Service. She had suffered multiple injuries, and the neck condition was not discovered until she was allowed to sit up. Then she complained that her head fell forward. Roentgenograms were made, she was placed in a plaster collar just as she was and shipped North. On arrival, head traction by means of a Stookey mattress was instituted and maintained for eight weeks. Incidentally, she had a broken jaw wired to her maxilla. Reduction was accomplished by the second day. She wore a leather collar for six months. All motions of the neck are now, seven years later, slightly limited.

Case 3.—A post-office clerk, aged 50, appeared in the outpatient department complaining of pain and increasing stiffness in his neck of about six months' duration. He remembered being knocked down by a car about that time but didn't think it had hurt him much. His head protruded forward and was held rigid. A mass of bony hardness could be palpated in the posterior pharyngeal wall. Roentgenograms revealed a complete forward dislocation of the first cervical vertebra with a fracture of the odontoid. No neurologic findings were made out. After forty-eight hours of 10 pounds head halter traction, reduction of the dislocation was complete. Because of discomfort, he was transferred to a Stookey mattress until a leather brace could be made. After three weeks he was allowed up in this collar, which was kept in place for seven months. He went back to work in his collar. He was followed for six years and, when last seen, had moderate limitation of all neck motions with occasional bad weather ache. At no time did he have neurologic signs or symptoms. The odontoid united by bony union, but there seemed to be residual spreading of the elements of the first segment.

These three cases illustrate two relatively successful results obtained by traction and the late result in an unreduced dislocation.

Far less dramatic and, on the Presbyterian Fracture Service, far more frequent are the incomplete unilateral dislocations. We have seen 300 during the past eleven years. The picture is typical: a jerk of the head in an unguarded moment, as on awakening, followed by immediate disability with usually mild pain; the head held tilted away from the affected side; markedly limited lateral bending to the affected. Stereoscopic roentgenograms from each side usually show the upward slipping of one articular facet on the one beneath it.

The condition must be differentiated from

torticollis in which the muscle spasm is on the short side, the side toward which the head is tilted. In a partial dislocation the muscles on the short side are relaxed, on the affected side they are in spasm. In cervical arthritis there is usually a moderate limitation of motion in all planes and no characteristic attitude of the head. Acute cervical adenitis may cause a protective attitude of the head, but the cause is usually easily ascertained. Myositis of the trapezius or "stiff neck" is primarily painful, and the tenderness is found in the affected muscle.

Treatment consists in reduction by any means that will relax the muscle spasm and allow the articular facet to slip back into place. Head halter traction, manipulation, and general anesthetics have all proved successful. Recently, following the suggestion of Dr. Hans Kraus, reduction in early cases has been accomplished by the use of ethyl chloride sprayed on the neck to give a slight skin anesthesia, followed immediately by active motions of the neck. As the patient moves the neck slowly in extension and flexion, from side to side as far as possible, the painful areas are sprayed for a few seconds at a time. It is surprising to watch the range of painless motion gradually increase, and one patient, a doctor, said that he could feel something slip. It may have been wishful thinking on his part. However, he regained complete lateral bending in fifteen minutes. Care must be taken not to burn the skin by too enthusiastic use of the spray. Active motion by the patient is essential, for the ethyl chloride alone is not enough. Its action is probably to relax the protective muscle spasm and allow the patient to reduce his own subluxation.

No immobilizing collar is used after reduction, and the patient is encouraged to exercise his neck muscles at frequent intervals. The method has proved successful in 10 recent cases but has not been satisfactory in partial dislocations that have persisted for several days. If reduction is not accomplished in twenty minutes to a half an hour, the method should be abandoned for some other. So far the results have been good, but the number of cases is too small and the time elapsed too short to do more than suggest it as a possibility.

Discussion

Dr. R. D. Severance, Syracuse, New York—The choice of this subject is an appropriate one, and I hasten to congratulate Dr. Stimson for her choice and the comprehensive presentation of the subject matter. Her presentation illustrates an adequate experience, fortified by a comprehensive knowledge of the literature. I can but re-emphasize a few of the points made by her. We cannot adequately stress the necessity of intelligent care at the site of the accident. To illustrate this, I shall cite 1 case. A boy, aged 17, missed his footing diving, struck bottom, was helped ashore and, while lying on the beach, moved both arms and legs. He was hastened by ambulance four or five miles to a hospital; on arrival he was totally paralyzed below the neck. He said that the ambulance went over a bump and that he felt stinging pain in his neck and realized he could no longer feel his arms or legs. He died after a long hospital stay. Physicians should grasp every opportunity to emphasize this fact to lay people.

I should like to caution against the indiscriminate use of a general anesthetic for the reduction of a dislocation. Adequate relaxation can usually be obtained by a large dose of morphine and the injection of a local anesthetic into the cervical muscles. Although cord damage can be done without the patient feeling it, it is much less likely. When using skeletal traction, we have applied as high as 36 pounds continuously for as long as three days. The case on whom we used this amount of weight was also manipulated unsuccessfully, and his reduction was never accomplished. He was seen four weeks after injury, and x-ray films five weeks after injury showed callus formation, preventing reduction. The four weeks' case, which Dr. Stimson referred to, was a most fortunate one. I wonder whether this reduction could have been accomplished at this time if it had been complicated by a fracture at facets or pedicles.

We have had no experience in fusing cervical spines for dislocations or fractures. We have had but one recurrence—a dislocation that recurred at the end of two years—upon whom we recommended a fusion; it was refused.

I have reviewed our cases for the past five years and they show certain trends, although numbers are too few for conclusions (see Table 1).

Table 1 tends to show that the death rate from cervical fractures is low under 50 years of age but approaches nearly 50 per cent over that

age. About one-third of all the cases over 50 years old were complicated with skull injury. All of these complications died. About one-quarter of the cases over 50 years old showed dislocations. Of the various causes of injury there is but one significant figure—3 cases resulting from football injuries, 2 of which were complicated by some paralysis and a most gross injury, resulted in complete recovery.

I should like to call attention to the great danger of overlooking an injury of the cervical spine when a patient is seen with a head injury. Whenever feasible, an x-ray of the cervical spine should be made in the presence of head injury, at least if the patient is unconscious. I should also like to suggest that if a cervical spine injury exists or is suspected an adequate supporting apparatus or cast be applied before any head surgery is performed.

We have encountered great difficulty in establishing a diagnosis of fracture in many cases presenting previous disease, notably arthritis. The presence of arthritis warrants a more guarded prognosis as to length of time for recovery and its completeness.

I am particularly interested in the unilateral dislocations or subluxations. We have seen a number of these, especially in the later teen age, but have had 1 boy aged 6. We have felt that such conditions can usually be reduced by manipulation without anesthetic, and we seldom use any fixation afterward. We have followed the various methods described and, if we are not fortunate enough to get a definite snap back into place, we use every trick we know and not a definite routine. The prerequisite to reduction is a continued uninterrupted manual traction for at least five minutes. The head and neck, of course, are held by the operator, projecting off from the table so that manipulation can be done unimpeded in any direction.

There is another type of injury which has been a source of considerable discomfort to patients whom I have encountered. There is an injury that has most frequently occurred when the car is struck from the rear while the patient is sitting in a parked car or riding along. It probably should be called a sprain but, because of circumstances of the injury, I have called it a neck snap. The patients feel immediate discomfort in the neck, in slight degree. They are usually excited at the time and do not think much of the injury. It is frequently followed by nausea, a little dizziness, and sometimes vomiting. The patient does not go to bed but stays up and about, and the symptoms persist over a period of weeks and even months. I have found some numbness over the shoulder and outer side of the arm at times, but usually there are no findings except tenderness in the upper one-third of the neck and laterally down over both sides of the neck. X-rays have been entirely negative. The relief has been by the use of a soft supporting collar and occasionally traction at night. This type

of case is greatly complicated by a pre-existing arthritis. It is in this type of case, where considerable change by arthritis is present, that we never feel sure that fracture is ruled out. The interpretation of films with a large amount of arthritis present is extremely difficult and uncertain, and I have often felt that it was unfair to state that a fracture did not exist. I have in mind a woman who received a snap of her neck by slipping from a step. She had considerable arthritic changes. She also fractured her forearm. She never complained of her forearm; in fact, it was reduced without anesthetic and without complaint. She had a considerable amount of sensory change, mostly of the right side, slight of the left arm with considerable motor involvement of the right arm. It would be unfair to say that this woman did not have a fracture or dislocation. It would only be fair to say she had a great deal of arthritis which prevented an accurate diagnosis as to fracture or dislocation.

In conclusion, I should like to re-emphasize the duty of all physicians to educate the public in the care of all spinal injuries at the time they occur and in the necessary care in transporting

them to some shelter. I also hope I have stimulated you to watch out for fractures of the cervical spine in the presence of skull fractures and to realize the necessity for fixation of the cervical spine before skull surgery is performed. May I again thank Dr. Stimson for bringing this subject to us and for focusing our attention to the excellent points she has made in her paper.

TELEPHONE ETIQUETTE

As we respond to a phone call, the voice at the other end of the line is heard to say:

"This is Dr. X's secretary. Will you hold the line a minute. Dr. X wants to talk with you."

And then we wait a minute—or two minutes—or possibly more.

This happens frequently to all of us. We doodle for a minute or two while busy Dr. X comes to the telephone after his secretary has made the contact. It would be more courteous if Dr. X had made the call himself, doodled for a little while waiting for us, and then greeted us personally when we spoke into the receiver. It would have flattered us if he had assumed that we were as busy as he or that our time was worth as much as his.

Relatively speaking, this is a small matter. How our telephone contacts are made will never change the course of history, but in a world in which courtesy is little thought of any more, it would be gracious to do the waiting on your end of the telephone line, rather than let a colleague's nerves become frayed while waiting for you at the other end of the line.—*The Canadian Doctor*

FOUNDATION TO TRAIN PSYCHIATRISTS

The Menninger Foundation, recently organized at Topeka, Kansas, is for the purpose of training psychiatrists and giving postgraduate psychiatric training to physicians in other fields, to carry on psychiatric research, to provide treatment to a representative group of patients who are selected not because of their ability to pay but for their specific needs and their intelligent cooperativeness, and to carry on preventive activities through adequate scientific child study.

Dr. Karl A. Menninger is president of the foundation; John R. Stone, vice-president; Dr. William C. Menninger, secretary, and Dr. Robert P. Knight, treasurer. The other trustees include prominent psychiatrists and philanthropists from various cities.

One of the first projects of the Foundation was the partial sponsorship of a week's seminar last summer on military psychiatry which concerned the neuropsychiatric examination and selection of men for the army under the Selective Service System. The material was published in the *Bulletin of the Menninger Clinic* and the distribution has been over 5,500 copies.

TIPS—FOR YOU WHO ARE WRITING A PAPER

Before you begin the first draft you will do well to read Katherine Frost Bruner's "Valedictory Remarks on Style" in the January issue of the *Journal of Abnormal and Social Psychology*.

Miss Bruner has had much experience in editing scientific papers and tells not only their common failings but offers constructive many suggestions.

EXPERIMENTAL ACUTE GASTRIC ULCER PRODUCED IN ANIMALS BY EXPOSURE TO SULFUR DIOXIDE GAS

F. R. WEEDON, M.D., Jamestown, N. Y.

IN THE course of studies still in progress on the effects of certain toxic gases in low concentrations on a variety of animals and plants, ulcers of the stomach were observed in mice and guinea pigs. These studies were carried out at the Boyce Thompson Institute for Plant Research, Inc., Yonkers, New York, by me and members of the staff of the Institute.²⁻⁴ It is the purpose of this paper to discuss some details of the ulcers arising in these animals exposed to sulfur dioxide.

There are two clearly different types of gastric ulcer—the familiar chronic ulcer, which is usually single, small in diameter, confined to the pyloric region, and which tends to perforate all layers of the organ; and the acute ulcer, which is usually multiple, may be large, is commonly on the greater curvature, and usually does not penetrate below the submucosa. In addition, there is an intermediate group in which the lesions tend to be large and are found on the greater curvature but which show definite chronicity, are frequently single or in small numbers, and tend to perforate.¹

According to Mann,¹ chronic gastric ulcers in his experimental animals first appear as thin gray plaques of necrotic tissue on the free surface of the mucosa, the necrosis and digestion then proceeding downward, no notable hemorrhage occurring at this stage; whereas in the acute ulcers the process apparently begins with a hemorrhage in the submucosa which extends to the overlying mucosa with subsequent digestion—a lesion well-termed “hemorrhagic erosion.”

The ulcers to be discussed here have certain characteristics of each group in that while usually multiple they may be single or in small numbers, may begin as necrotic plaques in the mucosa without hemorrhage but later bleed into the deep tissues and often perforate, yet may occur characteristically on the greater curvature and have never been observed in the duodenum.

Apparatus

The apparatus used in this study has been described in detail by Setterstrom and

Zimmerman⁵ and consists of duplicate sets—one for treating animals or other organisms with the gas, the other for controls. Each set includes a glass cabinet of special design, a variable speed exhaustor-blower and an orifice meter for precise control of the volume of air passing through the cabinet, a Thomas autometer and a Leeds and Northrup micro-max conductivity recorder for recording gas concentrations in the cabinet, besides other appliances described elsewhere.^{2,6}

Design of Experiments

Since the principal interest in the original experiments was the toxicity of the gas, the design was such as to determine the time until death of 50 per cent of the exposed animals as a function of concentration. The 50 per cent point was chosen because such a figure can be obtained with greater precision than any other time versus kill value.⁶ It is obvious that this point has no direct relation to the characteristics of ulcers. Several factors such as exercise and intermittent exposure were studied simultaneously but will not be analyzed here.

Experimental Procedure

Full details of procedure may be found in the paper by Weedon, Hartzell, and Setterstrom,² except that although the history of each vertebrate animal has been traced through the many hundreds of pages of “log-sheet” observations and necropsy protocols it was not felt that these voluminous data were important enough to publish in full.

The guinea pigs were weighed at least once a week and a record was kept of their food consumption. They were continually supplied with oats and were given a daily ration of carrots or cabbage. No other water was given.

The mice were watered and were fed “complete ration” dog pellets daily, with occasional rations of cow’s milk.

Experimental Results

Experiment No. 1 (63.7 p.p.m. SO₂).—Ten mature guinea pigs were treated with SO₂ and an equal number of similar guinea pigs were used for controls. On the first day the test animals ate well but after this showed

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

loss of appetite. On the fourth day 1 animal became dyspneic, and by the eighth day all were dyspneic. By the ninth day several guinea pigs had visibly distended abdomens. The fifth animal died on the fifteenth day (50 per cent end point). The surviving animals quickly recovered after removal from the gas except that those with distended abdomens remained in this condition for many hours. At necropsy one-third of the total number of test animals showed distention of the stomach, but no hemorrhages or ulcers were observed grossly.

Experiment No. 2 (10.7 p.p.m. SO_2).—This experiment was designed to test the effect of a concentration representing the maximum that might be encountered for any length of time in a city atmosphere. Ten guinea pigs and 10 mice were exposed.

Result: There was no observed change in the test animals.

Experiment No. 3 (33 p.p.m. SO_2).—*Result:* There was no observed change in the stomachs of the test animals.

Experiment No. 4 (25.9 p.p.m. SO_2).—This concentration of SO_2 is frequently encountered for short periods in certain industries.

Result: There was no significant change in the stomachs of the test animals.

Experiment No. 5 (25.3 p.p.m. SO_2).—*Result:* No significant change was found in the stomachs of the test animals.

Experiment No. 6 (109 p.p.m. SO_2).—*Result:* The stomach was usually distended. No ulcers were found grossly, but two stomachs showed large perforations that presumably originated in ulcers.

Experiment No. 7 (151 p.p.m. SO_2).—Distention of the stomach was usual after about forty-eight hours. About 15 per cent of the animals that died showed multiple ulcers from pin-point to 0.3 cm. diameter. The larger ulcers were all accompanied by circular sub-jacent hemorrhages of the wall.

Experiment No. 8 (296 p.p.m. SO_2).—Abdominal distention was pronounced on the third day in the guinea pigs. The 50 per cent end point for the mice was at forty-five hours, but distention was usual in the last few hours. Practically all of the animals showed multiple ulcers and sub-jacent hemorrhages of the stomach, larger and more numerous than those in the previous experiment, frequently coalescing and, in a number of animals, perforating.

Experiment No. 9 (1,014 p.p.m. SO_2).—Distention was observed after about three hours

FIG. 1.

but was not as great as in previous experiments. The 50 per cent end point for guinea pigs under ordinary conditions was twenty-three and one-half hours and in mice four and three-tenths hours. Multiple small ulcers and hemorrhages were found in the guinea-pig stomachs; in mice the lesions were rare and pin point in size.

Gross Pathologic Findings

The ulcers are from pin-point to about 0.5 cm. diameter except where they coalesce or perforate. In the latter case they may occupy half the anterior surface of the stomach. The structure can be seen clearly through the distended translucent stomach wall and in the smaller lesions appears as a gray opaque disk on the surface of the mucosa. Then it appears as a slightly larger, more opaque, ring or funnel, the center being digested. In the third stage a pin-point hemorrhage appears deep in the wall which expands to a disk nearly as large as the lip of the ulcer, the latter, however, usually well defined in perspective above.

Histologic Findings

Upon section of a small ulcer there is seen a striking edema of the wall between the muscularis mucosae and the serosa, with engorgement of vessels causing a nodelike swelling of the entire wall at this point. In the fold of mucosa immediately above only the tip is gone—the lower cells degenerated with pyknotic nuclei but still in place. The adjoining folds of mucosa appear entirely normal (Fig. 1). In a slightly larger ulcer the edema has

FIG. 2.

extended laterally, and the wall beneath the now collapsing fold of mucosa is thinner than the adjacent wall. A small amount of free blood lies in the wall and in the mucosa above (Fig. 2). Finally, the original fold of mucosa lies as a thin mass of blood and detritus on the muscularis mucosae, the now hemorrhagic muscle of the wall is thin and disintegrating, thrombi may be seen in the small vessels, and even the serosa has bulged outward until its cells are flattened to half the thickness of those over the adjacent tissues (Fig. 3).

Discussion and Conclusions

These ulcers are always preceded by acute distention of the stomach, a phenomenon that in itself is not well understood. The effect of the resulting pressure on the vessels branching from the large vessels of the wall to supply and drain the folds of mucosa may well account for part of the pathologic picture.

It is possible that the ingested acid gas may hasten the digestion of the necrotic mucosa, but in view of experiments with other gases as yet incompletely studied this conclusion should not be drawn from the present data.

Both distention and ulceration are functions

FIG. 3.

of concentration of SO_2 within proper time limits, and neither occurs at levels likely to be found in the air of any city. Thus, in Experiment No. 5, 14 guinea pigs and 30 mice were exposed under varying conditions of exercise, rest, etc., for 1,137 hours (about one-fifteenth the usual lifetime of a mouse), without effect.

Distention and ulceration are functions of length of exposure at proper concentrations. At 1,000 p.p.m. the 50 per cent death point was reached at about twenty-four hours in guinea pigs, and the ulcers were less numerous than at 300 p.p.m. for 153 hours.

Size and number of ulcers are also affected by concentration and time, the optimum conditions in these studies being 300 p.p.m. for about three days. Perforation, however, occurred at all concentrations that produced grossly visible ulcers, and the perforations were usually extremely large. These large lesions may have been caused by thrombosis of vessels larger than those usually affected.

Summary

The occurrence and nature of gastric ulcers in guinea pigs and mice exposed to controlled concentrations of sulfur dioxide have been described. Concentrations of 10, 25, 35, 65, 100, 150, 300, and 1,000 p.p.m. (in round numbers) were tested.

No effects on the stomach were observed below 65 p.p.m.

At 65 p.p.m. one-third of the animals showed

acute distention of the stomach on the ninth day, and at 100 p.m. half the animals showed distention about the fourth day, while two perforations of the stomach occurred. At 300 p.m. most animals showed distention and multiple hemorrhagic ulcers on the third day. Perforations were frequent. At 1,000 p.m. the ulcers were less frequent and of smaller size, but the life span was shorter.

The gross and microscopic appearance of the lesions has been described.

BUSINESS WOMEN PROMOTE HEALTH EXAMINATIONS

The National Federation of Business and Professional Women's Clubs, Inc., under the presidency of a physician, with a health advisory committee under the chairmanship of a physician, and with one additional medical member, one dental member, and three lay members, has issued a leaflet entitled "Are You Fit for the Job?"* This pamphlet explains the health appraisal project of the federation, recommending an annual physical examination for every business and professional woman.

The pamphlet analyzes the importance of health and fitness for the job. It sets forth three health ratings—the ideal, which is never wholly attainable; the actual, which is "often far below that which is possible and practicable for the individual," and the attainable, "the health that one might have with the normal appreciation and realization of health that is reasonably available for the individual." The pamphlet reproduces a health-appraisal form which is to be offered the examining physician. It includes a philosophy of health and fifteen points in a healthy personality.

The pamphlet also supplies instructions for health-appraisal projects for local business and professional women's clubs, including a meeting for discussion to be followed by efforts to attain 100 per cent physical examination by physicians, followed by appropriate corrective measures.

Accompanying the pamphlet is a four-page,

letter-size folder carrying on its first page an introduction "To the Examining Physician: The patient presenting herself to you for examination is a member of the National Federation of Business and Professional Women's Clubs who wishes to obtain the optimal level of health possible for her She is presumably a well person actively engaged in business or in a profession This examination form has been prepared to include not only a record of physical history and physical findings but also the questions which will aid you and the patient in evaluating her design for living which should make for an integrated personality. . . . Your cooperation in obtaining a complete history and giving a careful and complete physical examination will be appreciated."

Page 2 contains a form for recording an exceptionally complete health history; page 3 provides for recording a complete physical examination, including routine pelvic examinations recommended for all women, but states that special tests such as blood counts, roentgenograms, basal metabolic rate determinations, blood chemistry and the like are "recommended as indicated, but not included in routine health examination." The entire blank is to be returned to the patient for her information and subsequent guidance.

This is a well-conceived project which, if carried out locally according to the instruction so well developed by the national body, deserves the widespread cooperation of physicians.

—J.A.M.A.

SO YOU WANT TO WRITE?

Many of us want to, but few of us know how to. Here's a piece of advice Mark Twain once gave to a novice:

"I notice that you use plain, simple language, short words, and brief sentences. That is the way to write English—it is the modern way and the best way. Stick to it; don't let fluff and flowers and verbosity creep in. When you catch an adjective, kill it. No, I don't mean utterly,

but kill most of them—then the rest will be valuable. They weaken when they are close together. They give strength when they are wide apart. An adjective habit, or a wordy, diffuse, flowery habit, once fastened upon a person, is as hard to get rid of as any other vice."

—Talk, published by The National Hospital for Speech Disorders

NONSCHIZOPHRENIC CATATONIC STATES

MORRIS HERMAN, M.D., DOROTHY HARPAM, M.D., and MARCUS ROSENBLUM, M.D.,
New York City

IT HAS not been stressed in the literature that catatonic states occur in conditions other than schizophrenia. Following the work of Kraepelin, catatonia has been included in the group of mental diseases of the schizophrenic type. However, since that time it has been apparent that this grouping has been too rigid. The clinician has recognized numerous cases in which catatonia has been present but in which schizophrenia did not exist. Thus, this catatonic syndrome has been described in cases of general paresis,¹ epidemic encephalitis,² alcoholism,³ head trauma,⁴ hysteria,⁵ diabetes,⁶ mentally defective children,⁷ narcolepsy,⁸ and hypnosis.⁹

Recently, the problem has been elucidated from the experimental angle. Catatonic states were produced in animals by the injection of bulbo-capnine¹⁰ which closely resemble the syndrome of human catatonia. After the administration of a small dose the animals show: (1) catalepsy—the active retention of postures; (2) negativism—passive or active resistance to change of attitudes already assumed; and (3) autonomic phenomena—e.g., polypnea and salivation. After the administration of a large dose the animals present hyperkinesia and abnormal postures.

De Jong and Baruk¹¹ have been able to produce the catatonic syndromes in many different ways—i.e., by administration of a great number of chemical substances, by electric currents, by certain surgical procedures on the brain, and by experimental autointoxication. Their work in the last category is of particular interest. They produced lesions in the spleen, kidneys, testes, liver, and intestine in different animals. They found that there was no catatonic response after extirpation of the spleen, kidneys, or testes. However, they did obtain catatonia in 4 of 12 dogs in which they produced obstruction of the intestines. Also, catatonia developed in 16 of 24 cats surviving after ligation of the hepatic artery. In 2 of 4 dogs in which the function of the liver was partially eliminated by an Eck's fistula, an intermittent catatonia was produced. These authors conclude that experimental catatonia

is a frequent, and not a specific, reaction of the central nervous system and that biologically produced through autointoxication it occurs only following disturbances of the intestines and the liver. Another important observation is that experimental catatonia after the administration of bulbo-capnine does not occur in animals without a neocortex, such as frogs, so that in some way the cerebral cortex is concerned in the mechanism of the production of the catatonia.

Schilder¹² postulates that two factors are important in the production of catatonia—i.e., a cortical factor that produces a lack of impulse and a subcortical factor that produces a simultaneous innervation with minimum essential tone of the agonistic and antagonistic muscle groups.

Von Economo¹³ thought that the subcortical area responsible for catatonia in cases of epidemic encephalitis is the gray matter in the region of transition between the third ventricle and the aqueduct of Sylvius.

An important contribution to the study of catatonia has been effected by the work of Ingram, Barris, and Ranson.¹⁴ They produced lesions in cats in the base of the brain in the region of transition between the forebrain and midbrain by means of the Horsley-Clarke stereotaxic instrument. Their results show that the syndrome does not occur following extensive damage to the central gray matter of the aqueduct and third ventricle. However, catatonia was produced by bilateral damage to extrapyramidal structures in the hypothalamus in the region of the mamillary bodies, such as the posterior hypothalamic nucleus, the supramamillary area, the lateral hypothalamic area, and the region just caudal to the red nucleus. The symptoms produced in these cats have a remarkable resemblance to the catatonia following injection of bulbo-capnine and to clinical catatonia. The cats are described as having a pronounced lack of motor initiative, stolidity, subnormal emotional expression, an increased plasticity of the muscles expressed in the maintenance of odd postures, and a disinclination to eat so that artificial feeding is necessary.

In clinical material the catatonic syndrome presents an almost uniform symptomatologic picture, and the differential diagnosis of differ-

From the Department of Psychiatry, the New York University College of Medicine, and the Psychiatric Division of the Bellevue Hospital.

* Cases described in text

† We wish to acknowledge our gratitude to Dr. Israel Wechsler, director of the Neurologic Service, Mount Sinai Hospital, for permission to include this case

ent types is difficult. Kahlbaum¹⁵ describes catatonia as a disease picture "in which the patient sits quietly or completely mute and motionless, immovable, with a staring countenance, the eyes fixed on a distant point and apparently completely without volition, without any reaction to sensory impressions, sometimes with a full-fledged cerea flexibilitas, as in catalepsy, sometimes with a slight but definitely appreciable degree of this striking manifestation. The general condition of such a patient gives the impression of a deep mental distress or a fixedness resulting from a severe fright." Such a conglomeration of symptoms is found in schizophrenic mental disorders, as well as in other clinical conditions in which catatonia occurs. In order to demonstrate differential diagnostic criteria, a group of cases has been analyzed and will be presented with this point in view.

It is important to recognize, despite all these organic contributions to the study of catalepsy, that this condition may result from psychologic influences. It has already been pointed out that it occurs in hypnosis and hysteria. Furthermore, it may be produced in animals by rapid immobilization or other strong and unexpected stimuli.¹⁶ It is a common conjuror's trick to induce a cataleptic state in birds by suddenly inverting the creature and placing it on its back.

Table 1 presents 12 cases of which 4 are central nervous system syphilis; 2, epilepsy; 3, psychoses due to alcohol; 1, psychosis due to illuminating gas poisoning; 1, psychosis due to aspirin poisoning; and 1, psychosis due to head trauma.

Certain of these cases (those marked with an asterisk in Table 1) are described in greater detail as follows.

Case Reports

Case 3.—A. P., Austrian, aged 38, was brought to Bellevue Psychiatric Hospital by the police because he had been found wandering about making noise and was unable to give an account of himself. The patient was the only informant and on the fifth hospital day stated that he had suffered epilepsy since the age of 21. Physical findings on admission were remarkable only in that he exhibited waxy flexibility. The mental status for the first three hospital days revealed: intermittent mutism, a blank staring expression, occasional echolalia, and a clouded sensorium. He was discharged to a state hospital somewhat improved on the ninth day, but still revealed sensorial defects.

Case 4.—G. B., American, aged 34, was admitted to Bellevue Psychiatric Hospital because of the sudden onset of noisiness and irrational speech in the course of a prolonged alcoholic bout. He was a night club entertainer. His personality was described by an identical twin brother as selfish, dependent, and unfriendly. He was wont to curse his effeminacy. The only physical finding of positive value on admission was unreactive pupils. On the third day after admission he developed generalized tremors, changing rigidities, and grasping and sucking reflexes. His gestures were catatonic and he often held postures for long periods. The mental status revealed: blank staring, echolalia, perseveration, auditory and visual hallucinations, and a clouded sensorium. He was discharged on the thirty-third day to a state hospital, greatly improved physically but retaining a psychosis of an organic type.

Case 5.—L. F., Italian, aged 41, was admitted to Bellevue Psychiatric Hospital because of personality changes and odd behavior of three years' duration. A painter by trade, he was no longer able to keep a job because he mixed paints wrongly and had become generally incompetent. There was a history of moderate alcoholism. His personality as described by a niece was of the so-called schizoid type.

Physical findings of positive value were: slight irregularity of the pupils, a slight lingual and digital tremor, hyperesthesia, and cerea flexibilitas.

The mental status revealed: blank staring, entire absence of spontaneous speech with frequent and prolonged periods of mutism; occasional echolalia; jaw negativism, and sensorium which at the onset could not be adequately evaluated but which on subsequent examinations proved to be clouded.

Blood and spinal fluid serology revealed a 4-plus Wassermann and the spinal fluid colloidal gold curve was of the paretic type.

He was discharged, unimproved, to a state hospital on the sixteenth day.

*Case 6.**—J. T., white, aged 46, was admitted to the neurologic ward of Bellevue Hospital because he was in a clouded uncommunicative state. There was a history of his having been found in the street three days prior in a semicomatose state with evidence of head injury. The only physical finding of positive value was a right hemiparesis. The spinal fluid was pink, and a roentgenogram of the skull revealed a linear fracture of the vault. In the hospital he developed marked cerea flexibilitas and loss of sphincter control.

The mental status revealed a clouded sensorium. This condition deepened with the onset of drowsiness some days later. On the twelfth hospital day a large subdural hematoma was removed on the left side. The patient recovered with a residual of hemiparesis and was discharged to go home on the thirtieth day.

Comment

The catatonic symptoms in all the types of cases are identical with those found in schizophrenia. However, an examination of the sensorium shows that in these cases of organic brain disease there is a state of organic confusion—i.e., there is profound disorientation and marked cloudiness of the state of consciousness. This is not found in cases of catatonic schizophrenia. It is often difficult to probe the sensorium where there is mutism and marked negativism. Frequently, the catatonic symptoms are intermittent and subside sufficiently to allow temporary communicability. In more stubborn cases special methods

may be necessary. A mute catatonic patient may be persuaded to communicate by means of writing. This graphic method has been utilized even therapeutically.¹⁷ Contact may be obtained by the inhalation of a mixture of CO₂ and O₂¹⁸ and also by the intravenous injection of sodium amytal.¹⁹ These chemical agents act by removing the catatonic phenomena.

An analysis of our cases and those reported in the literature suggests that we can group them into three categories:

1. Cases in which cortical damage is predominant. In these we find catatonic symptoms accompanying a state of mental confusion of the organic type. This occurs in cases of general paresis, alcoholic encephalopathies, head trauma, carbon monoxide poisoning, acetylsalicylic acid poisoning, and in post-convulsive states.

2. Cases in which psychologic factors appear to be predominant, acting in certain constitutional types. Here, the catatonic symptoms are present without a state of organic mental confusion. This type is found in schizophrenia, certain hysterical states, and hypnosis.

3. Cases in which damage to the hypothalamus is predominant. Here, the catatonic symptoms are present with a clear sensorium but commonly associated with disorder of the sleep mechanism. This type is found in epidemic encephalitis and the narcolepsies.

Theoretically and by experimental results, one can hypothesize that catatonia is a neurologic phenomenon, the mechanism for which resides in the posterior part of the hypothalamus. It seems also that the neocortex has a controlling influence over this mechanism. This cortical influence is disturbed by the overwhelming toxic factors of organic cortical brain disease and also by psychologic influences. Certainly psychologic factors are important in the production of the catatonic state in hypnosis and certain conversion hysterias. However, the relative importance of psychologic factors in the production of catatonia in schizophrenia is not yet established. The cerebral control may also be disturbed by disease of the hypothalamic region—i.e., by cutting off the lower centers from cortical influences.

Summary

1. The experimental studies on catatonia have been reviewed.

2. Cases of catatonia in nonschizophrenic subjects are analyzed.

* We wish to express our gratitude to Dr. Foster Kennedy, director of the Neurologic Service, Bellevue Hospital, for permission to quote this case.

3. The catatonic symptoms are identical with those found in schizophrenia.

4. The clouded sensorium found in organic brain disease differentiates the catatonia of these cases from that of schizophrenia.

DO YOU KNOW WHAT "BEDLAM" MEANS?

Doctor Jones says, in *Health News*: "My mother, when I was a boy, when a bunch of us got to making a terrible commotion, she'd come in: 'What's all this bedlam about?' she says. Or maybe she'd say we sounded like a 'mad-house' So I figured they meant about the same thing. But, you know, I've just discovered it was originally Bethlehem: the Bethlehem Royal Hospital for lunatics, as they used to call 'em. That was way back in the fifteenth century, in London. It was a pretty tough place, I guess. I was reading they even let people in for an admission fee to see the inmates. If they didn't perform to suit 'em they'd poke 'em with sticks. Today you'd probably get pinched if you tried to do that to wild animals in the zoo.

"What started me on this: I was just reading a lecture Dr. Hutchings gave in this 'March of Medicine' series. 'The Ascent from Bedlam'—that's the title of it. He was superintendent for years of the Utica State Hospital. He's one of the old-timers in the mental business that's kept up on what they call the new psychiatry: preventive measures, psychoanalysis, and all that.

"It's a remarkable story—this lecture is, of the gradual change in ideas and methods from the old days when people with mental disturbances—they used to light fires under 'em and all that stuff to drive out the demons. Of course old

Hippocrates, way back there B.C., he said it was disease and not devils. But that idea was too newfangled to make much impression. In fact way along in the seventeenth century casting out devils was a thriving business. One bunch of church folks reported that they'd cast out 12,652 of 'em.

"Back in those days they weren't patients and they weren't treated. They were just mistreated. But in Paris, in 1792, they put a fellow by the name of Pinel in charge of an asylum there: a place about like old 'Bedlam.' He had some ideas of his own, Pinel did. He unchained the inmates, gave 'em beds to sleep in and something to occupy their time, like working in the garden and so on, and some of 'em improved. Most of the people around there were busy putting on the French Revolution; otherwise I s'pose Pinel'd have lost his job. Something more or less the same was going on in England. That was really the beginning of giving 'em decent care—these mental cases.

"What Dr. Hutchings calls the 'new psychiatry' began to take hold along about 1909. It got its start, he says, from the 'epoch-making studies' of Dr. Freud. Now they not only treat 'em scientifically and cure a lot of 'em but they aim to prevent these troubles. Well—time's marching on, too. We'll have to finish this some other time."—Paul B. Brooks, M.D.

A NUTRITIONAL MOVIE

"Hidden Hunger," a two-reel picture made as a part of the National Nutrition Program and presented by the Federal Security Agency, brings to the screen in an entertaining and understandable manner the newer knowledge of nutrition. It points up waste of food through improper cooking and waste of money through improper buying.

It shows and tells the minimum essential foods a man should eat every day for maximum health: 1 egg, 1 pint of milk, two vegetables (green, leafy, or yellow), and a potato; an orange or tomato juice and another fruit; three or more slices of the right kind of bread (whole wheat or enriched white); two tablespoons of butter or margarine; and meat.

Special Article

A CONSIDERATION OF THE HANDICAPPED—PARTICULARLY THE BLIND MASSEUR

DAVID R. SALMON, New York City

EDUCATORS, industrialists, and other groups conferring in a spirit of sympathy on the problems of the industrial rehabilitation of the handicapped will find their well-intentioned gatherings unproductive unless a definite, constructive plan is drawn up wherein the rehabilitation processes lead toward assured jobs in industry. This calls not only for industrial job surveys by these groups but also for an intensive publicity campaign to overcome unwarranted public prejudice against employment of the handicapped. It cannot be overemphasized—vocational rehabilitation of the handicapped entails a rightabout-face by the public in its general acceptance of handicapped labor.

Well-directed publicity is of particular value now while each man's contribution toward national security is most urgently needed. It may be safely said that more can be done in one war year to aid the handicapped as economic producers than in several peaceful decades. Our government should not miss this opportunity to set these people to work and to educate the public as to their capabilities. It is also worth contemplating whether or not special government consideration should be given to those industries employing a certain percentage of the handicapped.

While the blind masseurs are not in need of vocational rehabilitation, they are a handicapped group in need of jobs. By giving this group cooperative support the medical profession can serve as an example for other groups to do likewise.

There are approximately twenty-five competent blind masseurs licensed by the City of New York. They have all had hospital or private patient experience or both. Eighteen of their number are chartered as the National Association of Blind Masseurs with headquarters at The Lighthouse, 111 East 59th Street, New York City. While they are not physical therapists, they have been trained to use electrotherapy under sighted supervision. The development of a sensitive touch sense, the ability for full concentration

free from the distractions of the seeing world, plus the other qualities of physical fitness, education, and personality which are necessary in the capable masseur make the majority of this group highly employable.

The blind masseur encounters difficulties because of the inability of the layman to separate special capabilities from the idea of handicap in general. The medical profession in England, through its cooperative support, is largely responsible for revealing the skill of the blind masseur to the public, and a livelihood in his chosen field has thus been opened to him.

In considering how the medical profession may aid blind masseurs in this country, it is well to consider further what the English have done. Before entrance is granted to the Eichholtz Institute of Massage and Physiotherapy for the Blind in London, the prospective blind masseur is required to furnish a consensus from at least six medical men in the district in which he hopes to practice that there is scope for the masseur in the locality and a promise that they will consider helping him by sending him patients. Further, he is asked to produce some indication from the local authority of his area that it will use its influence to secure for him a hospital appointment.

In England, blind masseurs may not advertise, but in this connection the Association for Certificated Blind Masseurs, which corresponds to our National Association of Blind Masseurs, is able to undertake suitable forms of advertising and to arrange for general publicity so as to keep the work of the blind masseur constantly before the medical profession and the general public. The Association has strong medical backing, and advertisements are inserted in medical and lay papers describing the qualifications of its members.

The American medical profession can aid the blind masseur by similar cooperative support when he is certified. Means of advertising can be provided through medical papers, and the example can be set for lay papers to follow suit. Recognition of the merits of the blind masseur can be extended by inquiring at the New York Association for the Blind for the names of one or two members

Vocational Guidance and Placement Counselor, The New York Association for the Blind and the New York Institute for the Education of the Blind.

of the National Association of Blind Masseurs to be used as alternates on physicians' lists.

Sightless masseurs, accepting the realities of their present position, are willing to receive a fee smaller than that generally accepted by

sighted masseurs. They have faith in their abilities and believe that in time they will come into recognition.

Now is the time to consider how we may improve the lot of the handicapped in general. Here is an opportunity to aid a specific group.

VICTORY AND LASTING PEACE DEPEND ON CIVILIAN UNITY

"Two war phrases, 'unified command' and 'grand strategy,' are being heard with increasing frequency. Use of them obviously is made in connection with military action. But they must now be extended to include civilian action. That has a special significance to the army of Bundles for Britain volunteers throughout the country.

"Britain cannot win the war alone; we cannot win it alone. Each nation has promised the other full support, and for that full support each nation's army and navy are undertaking operations under unified agreement, according to grand strategy. But the armies and navies cannot do the entire job. The civilian populations have a job of their own, to help take care of themselves. The civilian populations of America and England are factually one, a great unified group of people, working for a common protection and common aid.

"At this time, America fortunately is not in the dire need in which England stands. We still have enough for ourselves to be able to help her, and keep on helping. Yet we shall not be helping a country called England as much as a land which in this emergency has become our alter ego, our other self.

"Therefore one can say to the men and women of the American home: 'You are strong, you are able, you are kind, so give your strength, your ability, and your kindness, not only to those within your own land, but also to those outside, without whose collaboration your ramparts can-

not stand.' This is not sentiment or emotionalism. It is the soundest policy for winning the war, because it is the application to civilian life of the theory of unified command and grand strategy.

"It is also well to remember that we committed ourselves to a job which must continue. Bundles for Britain and other war relief agencies were founded to help the people of a country in distress. Those people are still in distress. To decrease our efforts in their behalf now that we face having our own distress, would be as if we said: 'Now that we are hit, we cannot think of you.' This would be in contradiction to the concept of unified command and grand strategy which the leaders of our two countries are so trying to perfect. So we must continue wholeheartedly and untiringly the efforts to help Britain's stricken civilians. In that way we say to them: 'Even though we are hit, we still think of you.' If we were in England's plight and England in ours, we would cherish such a spirit toward us from Britain. It is for us to establish a precedent for the behavior of people of all nations in the future.

"This is war, but also war for a peace, and that peace will be strong and lasting in proportion to the ability of people to work together for a common good. Ultimately this will be the basis of the contribution the United States and Great Britain will make to the future.—Raymond Gram Swing, in *The Lion Rampant*

DOCTORS' ORCHESTRA SOCIETY IN NEW YORK CITY PREPARING FOR CONCERTS

The Doctors' Orchestra consists now of 60 physicians and dentists who are playing members of the orchestra. Professional musicians have been almost completely eliminated. The orchestra is at present preparing for two concerts: for the State Medical Convention to be held at the Waldorf-Astoria on April 28 and for their fourth annual concert to be held at Town Hall on May 8.

The program for the above consists of the Schubert unfinished, and the Beethoven second symphonies, Weber's *Euryanthe* overture, the Tschaiakowsky *Marche Slave*, together with a modern composition, and other smaller compositions.

The orchestra has been practicing throughout

the past year and has held weekly rehearsals at the Hospital for Speech Disorders, through the courtesy of Dr. James Sonnett Greene, director of the hospital. Under the tutelage of the conductor, Mr. Fritz Mahler, remarkable progress has been made and through the efforts of the new president, Dr. William Spielberg, the orchestra has assumed proportions very near to those of a professional symphony orchestra.

Tickets for the fourth annual concert on May 8 are now for sale and may be obtained from the chairman of the concert committee, Dr. Alexander Sved, Regent 4-8390, 654 Madison Avenue, New York City and from the president, Dr. William Spielberg, 235 East 22nd Street, New York City, Stuyvesant 9-4402.

Annual Reports

Medical Society of the State of New York

1941-1942

Report of the President

To the House of Delegates; Gentlemen:

PART I

This has been an unusual year of service. It is with great satisfaction that I am able to report to you that there has been an unusual spirit of mutual helpfulness and devotion in every committee, every county society, and among all the members of the Council in studying problems that have arisen because of the confused situation in the country while it is translating its energies from peacetime activities to alignment in support of our government's war effort.

This is no time in which to indulge in trite pomposities of phrase. The time for talk, and for discussions and arguments, is past. We must face facts. I shall, therefore, first briefly allude to our intramural activities, and, then in a second part, outline the shape which trends in medicine seem definitely to be taking under the stress of war.

In passing, I want to acknowledge the hospitality of the district branch societies, all of which I was privileged to visit during the year at the time of their annual meetings. These meetings were well organized and well attended and were fruitful both in scientific presentations and in discussions of medical import for the public welfare. The fine work in connection with these meetings which Dr. Joseph Lawrence does needs special mention. I refer you for details to the district branch presidential reports.

The Council of the Society will present a report of its activities, together with recommendations. These have been fully considered and merit your favorable attention.

I would be remiss in appreciation did I not remark on the business-like celerity of procedure and the fine way in which the subcommittees function under the chairman-leadership of one or another of the Councilmen. The pains of "new growth," the frictions, and the controversial cross currents of desires and ideas were totally absent this year. The Council has "found itself." The fine unanimity of opinion sought as the achievable goal on each proposition deserves remark. By invitation the Council opened its floor and discussions to any members of the Board of Trustees who desired to avail themselves of the opportunity, so that the Trustees might know the background and the reason for such recommendations as the Council desired to transmit to the Board.

Comment on my part is hardly needed on details of committee reports which will come before you. Suffice it to call your attention to the expanded program of postgraduate medical education. Lecture hours have expanded to teaching

days. This expanded program, stressing as it does industrial and war medicine and surgery, is peculiarly appropriate in these times. In addition there has been set up a Conference Committee to work with official agencies in a praiseworthy further effort to eradicate tuberculosis from our population.

Medical Relief is being continued in cooperation with the State Department of Social Welfare, to the end that the best available care shall be given to both the indigent and the near-indigent.

The relations of the Society to the various departments of the state government, of which you will have report, is exceedingly fine. There is cooperation and mutual good will, with the result that commonly sought goals are achieved. The appreciation of the Society is hereby expressed to the State Departments of Health, Education, Motor Vehicles, and to the Board of Regents. The Committee on Public Relations and Economics, and its manner of approach and its diplomatic handling of pertinent problems, deserves an accolade of praise.

The Legislative Committee has been commendably vigilant and vigorous. At this writing I am unaware of the final outcome of some of the pending legislation. The cooperative action of the committees on legislation of our component county societies is gratefully acknowledged.

There has been progress in our study of the developing programs of Medical Expense Insurance. The further development of these plans to overcome the financial handicaps preventing prompt medical and hospital service to those whom catastrophic illness strikes meets two threats: on the one hand, the government's proposition to give medical and hospital care to its social security clients, and, on the other, the efforts of the Goldwater group to break down the legal separation of medical from hospital care. I much fear that all our voluntary medical expense insurance plans will pass from the picture if the federal government's social security program, for giving its thirty-five million clients and their dependents both hospital and medical care, is put into effect. The discussions in which we have engaged as to the form and type of our voluntary plans will soon have only an academic value, because these voluntary plans will die if placed in competition with the government-sponsored plan. Need I add that the proposed new social security extension, with its necessary additional deductions from the worker's pay envelope, should be examined and thoughtfully studied by organized labor as well as organized medicine? The least that can be asked is a stay

for intelligent study by both of these groups vitally interested in the question.

The Workmen's Compensation Bureau, under its energetic chairman, is continuing to perform a valuable service to both the profession and the public. Dr. Kaliski's report merits your considered favorable action.

Publicity may be touched upon in its three branches—the *Directory*, our *JOURNAL*, and the other forms of publicity emanating from the Committee on Medical Publicity and its erudite director of public relations, Mr. Dwight Anderson. In all the branches of publicity a high level of excellence has been maintained. Wise business management has effected arrangements which have kept cost levels to no higher than before, notwithstanding the rise in prices of paper. This is true of both *JOURNAL* and *Directory*.

In passing, I must note for your satisfaction the strides which the prestige of the *JOURNAL* has made. Its literary contents, its editorials from the able pen of Dr. Laurance Redway, its dignity in expressing the adopted policies of the Society, are gratifying. In the uphill struggle to attain a place commensurate with the dignity and prestige of the Society whose views it represents, its steady progress in increasing reader interest, its better scientific articles, all bespeak steady growth and widening influence.

Finances.—There has been no more sincere worker in our midst than Dr. Edward Wentworth, chairman of the Council's Finance Committee. Here I would only add one suggestion for general consideration. I refer to the policy of remitting the dues of members who are called to the colors in our armed forces. The idea has my sincere approval, but I would suggest a modification of its application. I would restrict this to those physicians to whom, while in the service of their country with the armed forces, the payment of dues constitutes a burden and hardship, and limit it to those that ask for it. I needs must recommend this because, as I contemplate the expanding activities of the Society on the one hand, and the shrinking income from dues on the other (because many of our members will soon be with the colors), I realize that something must be done to balance matters. If we are not greatly to curtail our activities "for the duration," we shall either have to continue to receive as much money for dues as possible, or begin to live and go on functioning with money taken from our capital—our invested funds.

I shall report separately on the affairs of the Committee on Medical Preparedness.

Office Management.—This has greatly improved. In the heavy work as president in these particular times, it became necessary for me to visit the Society's offices almost daily. The splendid esprit de corps, of the staff, the devoted help tendered by the general manager, Dr. Peter Irving, and the many extremely courteous services rendered by everyone at the Society's headquarters, make up the one single factor which has made possible the smooth functioning of the interrelated committees. Furthermore, excellent relationships were established with army officials, the Mailer Commission, and other New York state agencies. All this brought about mutual good will and co-operation. Recently two new agencies have been largely serviced, as far as the state's doctors

are concerned, by the office, namely, the New York State Procurement and Assignment Service, and also the necessary contacts with the New York regional office of the Social Security Board. I report without mental reservation that without this freely volunteered help, and these cheerfully performed services, what success I may have attained would have been impossible.

PART II

Trends in Medical Affairs.—The war situation inherently means a temporary curtailment of the very liberty we are attempting to preserve. I readily concede that this is necessary where military exigencies require it. The government has both a moral and a legal right to take any and all measures which it deems to be necessary for its own survival and preservation.

There are those who believe that it is perfectly obvious that what is going on today has many elements of a social revolution, and they would improve social conditions generally under democratic institutions to meet the contingencies inherent in this social revolution. This school of thought proposes a profound revolution in our thinking in regard to medical care. What are we doing about it?

Without discussing the question of social revolutions while the war effort is getting under way, there are factors in the situation which I desire to bring to your attention.

The proposed federal plan which, for want of a better name, I shall call the "hospitalization tax program," I would have you study, with its wide implications. Under this plan many millions of workers and their dependents who are or who may become beneficiaries of old-age and survivors' insurance systems would have their hospital bills paid by federal funds. There is, furthermore, the implication that social security is to be extended, to the end that people permanently disabled before the age of 65 will be entitled to receive federal benefits. The determination of the disabilities will require medical examiners. Finally, the medical care of many of these people will become a public issue.

There arises the question of payments to workers during temporary disability. This requires medical certification at both the beginning and the end of each illness. For the treatment of the sick worker, a paid doctor would be necessary.

We must prepare studies as to methods of procedure for the handling of the medical care under these plans if, and when, they come into operation. But aside from the determination of procedure, here is a distinct trend toward a *system of state medicine*. In this connection I am not concerned with any details; I am concerned today only with the idea that the organized profession should recognize the trend and comprehend toward what we are drifting, and should prepare adequately for the part it democratically determines will be its attitude and role with respect to the propositions.

The second straw in the wind to which I call your attention is the federal rehabilitation program, which is at present undergoing tests in Maryland and Virginia to accumulate experience. This constitutes a program designed to have the federal government undertake the rehabilitation of rejected registrants coming under control of

the national Selective Service Law. The entire procedures contemplated are given in full in the *J.A.M.A.*, Vol. 118, No. 5 (January 31, 1942), page 382.

The respective state directors, through the channel of the local selective service boards, will enrol the physicians and the dentists and also the hospital facilities to do this rehabilitation work. The physicians, dentists, and hospitals will be paid at rates to be established on a fee schedule which is soon to be published. What part organized medicine played in developing this fee schedule—whether it takes into account the difference in medical costs in the metropolitan areas as contrasted with rural and industrial areas—I have been unable to learn. Meanwhile there is accumulating a national roster of physicians, who fill out very detailed blanks about themselves and enrol to do this work.

Having determined our stand in regard to these trends, the inexorable logic of events will either justify us or confute us. Let us not be bound to harmful policies, whatever the instant popular reaction to them may be. I deem it my duty to call them to your attention, for such action or instruction to your delegates to the American Medical Association as you may determine.

In these fast-moving times, we cannot be too watchful. I believe that everyone who thinks of the train of events which culminated in the war we are waging must realize that we are not only fighting a war, but also witnessing a social change. This you may call social revolution if you wish. I hold this to be true all over the

world. It is distinctly evident in England—to cite a people most nearly akin to us. This being so, it follows that in the social upheavals there are abundant dubious virtues. For the comprehension of these so-called virtues, intelligent interpretations are exceedingly necessary. We must accept one fundamental fact: an epoch has passed, and a new one is upon us. We may have a heartfelt nostalgia for the past epoch, in which medicine played its noble role, and contributed so richly to American life. As we note the present trends, however, we can observe the inevitable parallels which movements and currents in public affairs require that we comprehend. The earlier we understand them, and guide them, the better will organized medicine be served. Perhaps, too, we may be enabled to play a part in protecting the public welfare from the over-enthusiastic protagonists of trends which, in the long-range view, are not in the interest of either the medical profession, labor, or the public generally.

In conclusion, let me express my thanks for the cordial cooperation and enthusiastic support I have enjoyed at the hands of every official and many of the individual members of the Society.

In the year which has passed, I have been indeed highly privileged to serve during exciting times when history has been in the making. I have learned much by the experience.

I am deeply grateful both for the honor of having served, and for your confidence which I have enjoyed.

SAMUEL J. KOPETZKY, M.D., *President*
March 9, 1942

Report of the Secretary

To the House of Delegates; Gentlemen:

Since your last meeting on April 28 and 29, 1941, the administrative year has seen an expansion of the regular activities and the addition of new work. The headquarters office has met all ails. The coordination of activities has gone ahead smoothly.

Membership.—Elected in 1941 were 856 new members; 210 were reinstated. The net increase for the year, as shown below, was 372.

Membership—December 31, 1940.....	17,409	
New Members—1941.....	856	
Reinstated Members—1941.....	210	18,475
Deaths.....	198	
Resignations.....	144	
Licenses Revoked.....	3	345
		18,130
..... of 41		349
Total Membership, December 31, 1941.....		17,781

Honor counties (none of whose members failed of their dues in 1941) include Chemung, Columbia, Cortland, Essex, Fulton, Livingston, Montgomery, Onondaga, Schoharie, Schuyler, Seneca, Tioga, Tompkins, Warren, and Wyoming.

New York Office.—The revisions in system initiated last year and reported to you

then were in due course completed; and all procedures have been working efficiently in the new way. Thus, production of the *JOURNAL* and the 1941-1942 *Directory* has been facilitated and at the same time the increasing calls on the office for assistance in the field of medical preparedness have been met.

It has been of much help in office management to have the counsel of the special Committee on Office Administration and Policies, which you set up in 1940 and continued in 1941, to operate under supervision of the Council. This committee has met regularly. Because of its constitution with managing officials, general and special, the *JOURNAL* literary editor, the treasurer and a trustee, it has been in a position to fit varying needs of the office together in effective fashion.

Mr. Anderson, in his capacity as business manager of the *JOURNAL* and *Directory* and of Technical Exhibits for the Annual Meeting, has done yeoman service that has resulted in financial improvements in all three fields.

Coordination of Activities.—The Council with the help of its committees has fulfilled its duties during the year in brisk and effectual fashion and without duplication of effort.

It has been found wise to make some slight changes in the Council committee mechanism in such a way as to cover certain expansion in effort. A Joint Committee on Dental Health of the

Medical and Dental State Societies was set up. The Subcommittee on Maternal Welfare was reconstituted as the Subcommittee on Maternal and Child Welfare, with the same personnel but the addition of a pediatrician. Regional Chairmen in Pediatrics were appointed to parallel the Regional Chairmen in Obstetrics. A new Subcommittee on Industrial Health was created to study the problems resulting from the needs of wartime production that might call for additional postgraduate education courses in Industrial Medicine. Another new subcommittee has been recently appointed on War Medicine and Surgery, also to operate under the chairman of the Committee on Public Health and Education.

A new Council Committee on Hospitals has been set up to contact hospitals and the hospital associations.

The Committee on Scientific Assembly was recast as the Committee on Convention, with the subcommittees as before: on Scientific Program, Scientific Exhibits, and Arrangements. In this way it has been possible to pivot the different functions around the general manager.

The Committee on the Deaf and Hard of Hearing has been enlarged to five by the addition of four otolaryngologists.

At the instance of the Council, the president, Dr. Kopetzky, was drafted to succeed himself as the chairman of the Committee on Medical Preparedness, thus continuing the committee with the same personnel.

The work of this committee has increased and the office force has been continually at work. The job of finding examiners for the draft boards diminished, but a call of large proportions began in the winter of 1941 for civilian contract physicians to aid the Army Pre-Induction Teams operating in the state under the Surgeon of the Second Corps Area. This call has been met, again with the painstaking assistance of the county society committees.

Just recently, Dr. Arthur W. Booth, of Imitra, has been appointed under the Procurement and Assignment Service in Washington as chairman for the Second Corps Area, and under him Dr. Kopetzky has been delegated chairman for the State of New York.

Thus, another call has come to the State Society and to the county societies: for information that will help the Procurement and Assignment Service to decide which physicians are available for service in the Medical Corps of the Army and Navy (and other federal agencies) and which physicians are needed in their communities for civilian work.

It is with deep satisfaction that your general manager welcomes this opportunity for himself and for the office force to aid this important service.

Our two departments, the Bureau of Public Relations and the Workmen's Compensation Bureau, have been steadily at work in an effectual fashion, as always.

Mr. Anderson completed the radio program authorized by you last year and has effected in the same expert manner the other desirable medical publicity as shown in the Council report. Dr. Kaliski has continued his painstaking work in the interest of the physicians working under the compensation laws.

Your secretary again wishes to express his high commendation of the work of the Committees and the Bureaus, and his great pleasure in the many contacts in the course of the work.

In closing this report, I wish to take the occasion to extend my sincere thanks to the members of the general staff working under the able guidance of Miss Dougherty. Their work has been loyal, devoted, and unfailing.

Respectfully submitted,

PETER IRVING, M.D., *Secretary*

March 9, 1942

Report of the Council

To the House of Delegates; Gentlemen:

Your Council has the honor to report on its executive and administrative management of the affairs of the Society during the period following your last meeting on April 28-May 1, 1941. The various matters before it are here presented in successive parts.

PART I

Postgraduate Education

In accordance with the expressed desire of the House of Delegates of 1941, the Council has approved the further expansion of the postgraduate teaching work open to members of the Society. The same Committee has carried out the work as follows:

Oliver W. H. Mitchell, M.D.,

Chairman.....Syracuse
George Baehr, M.D.....New York
Charles Dayton Post, M.D.....Syracuse

Necessarily, the program of the year has called for more expenditure of the Society's funds, but this had had the approval both of the Council and the Board of Trustees. The following report

from the Committee summarizes the work of the year that has been done and is to come, with the approval of the Council.

REPORT

On June 11, 1941, the Chairman of the Council Committee on Public Health and Education called a meeting of the Committee with representatives of the State Departments of Health and Labor to discuss plans for postgraduate education for the coming year. Special consideration was given chemotherapy, cancer, dental health, industrial health, and rheumatic fever.

Following this meeting, all of the physicians who had arranged courses in previous years were sent letters asking their continued cooperation and suggesting the revision of some courses, in view of changes in speakers and the addition of the following subjects: chemotherapy, cancer, dental health, industrial health, and rheumatic fever. Meanwhile, letters to the presidents of the county medical societies described the proposed expansion of the work and the type of courses to be offered and requested that county

medical societies notify the Committee as soon as possible, specifying choice of subjects and dates. Twenty-one requests for information were received before the *Course Outline Book* was ready for distribution, and since that time twenty-one additional requests have been received.

During the summer months the Committee held several meetings in New York City for the discussion of routine matters and for special consideration of chemotherapy, dental health, industrial health, and rheumatic fever. All of these subcommittees initiated a considerable number of activities. At a meeting of the Study Committee on Industrial Health plans were discussed to determine the need and type of instruction which should be made available to physicians of the state. No formal course for any special area was prepared but instruction was made available on many subjects upon request and it was decided that an announcement of such a nature be included in the *Course Outline Book*. A meeting of the Joint Committee on Dental Health was held to discuss final plans for the instruction to be offered. Conferences were held in Albany with representatives of the State Health Department to prepare the program and arrange for instruction in chemotherapy and rheumatic fever. Announcements regarding these programs were prepared and included in the *Course Outline Book*. A conference was held in New York City with Dr. John J. Bourke, research director, New York State Health Preparedness Commission. The New York State program for civilian defense was discussed with Dr. George Baehr and Dr. H. van Zile Hyde of the Office of Civilian Defense. An announcement regarding the latter activities was prepared and appears in the *Course Outline Book*. Upon completion of these special announcements, the *Course Outline Book* was published and sent to county medical societies in the state, the State Commissioner of Health, division directors, officers of the State Medical Society, and members of the Committee on Public Health and Education, including the subcommittees.

This office has made arrangements for postgraduate instruction in twenty-seven county medical societies. The following is a list of the counties which have had, or will have, postgraduate instruction this year, with the subjects and number of the lectures.

County	Instruction	No. Lectures
Cayuga	Traumatic Surgery	7
	Public Health	1
Chemung	Pediatrics	1
Cortland	General Medicine	5
Columbia	General Medicine	7
Dutchess	Rheumatic Fever	1
Delaware } jointly	Rheumatic Fever	1
Otsego }	Obstetrics	2
	Cancer	1
	Traumatic Surgery	3
Franklin	Sulfonamide Therapy	6
Fulton	General Medicine	6
Jefferson	Sulfonamide Therapy	6
	General Medicine	5
Madison	Sulfonamide Therapy	7
	General Medicine	3

Monroe	Surgery	1
	General Medicine	1
	Medicine	1
	Nutrition	1
	War Medicine and Surgery	1
Montgomery	Dermatology	7
Nassau	General Medicine	4
	Pediatrics	4
Oneida	Sulfonamide Therapy	6
Onondaga	Sulfonamide Therapy	6
	War Medicine and Surgery	1
Orange	Sulfonamide Therapy	6
Oswego	General Medicine	5
Queens	Allergy	4
Rockland	General Medicine	6
St. Lawrence	Sulfonamide Therapy	7
Schoharie	General Medicine	6
Steuben	Traumatic Surgery	7
Sullivan	Pediatrics	7
Tioga	General Medicine	5
Washington	Rheumatic Fever	1
Westchester	General Medicine	5

Public health matters receiving particular emphasis from the State Department of Health and the State Medical Society this year have been cancer, obstetrics, pediatrics, rheumatic fever, syphilis, sulfonamide therapy, industrial health, and nutrition. The work of the Committee in these fields has, to a large extent, been in postgraduate instruction, and of the counties listed above the following have had instruction in one or more of these subjects, a share of the cost being borne by the State Department of Health:

County	Instruction	No. Lectures
Chemung	Pediatrics	1
	Syphilis	1
Columbia	Rheumatic Fever	1
Dutchess	Rheumatic Fever	1
Delaware } jointly	Cancer	1
Otsego }	Obstetrics	2
	Rheumatic Fever	1
Franklin	Sulfonamide Therapy	6
Fulton	Sulfonamide Therapy	1
Jefferson	Sulfonamide Therapy	6
Madison	Sulfonamide Therapy	7
Monroe	Nutrition	1
Montgomery	Cancer	1
	Syphilis	1
Nassau	Rheumatic Fever	1
	Pediatrics	4
Oneida	Sulfonamide Therapy	6
Onondaga	Sulfonamide Therapy	6
Orange	Sulfonamide Therapy	6
Oswego	Rheumatic Fever	1
Rockland	Sulfonamide Therapy	1
	Syphilis	1
St. Lawrence	Sulfonamide Therapy	6
Schoharie	Sulfonamide Therapy	1
Sullivan	Pediatrics	7
Washington	Rheumatic Fever	1
Westchester	Rheumatic Fever	1

The following is a list of regions which have had Teaching Days on Maternal and Child Welfare:

Region No. 12—Erie, Niagara, Chautauqua, Genesee, and Wyoming county medical societies at Buffalo on Thursday, October 16, 1941.

Region No. 4—Schenectady, Fulton, Montgomery, Schoharie, Greene, and Ulster county

medical societies at Schenectady on Thursday, November 13, 1941.

Region No. 2—Suffolk and Nassau county medical societies at Nassau Hospital, Mineola, New York, on Thursday, November 13, 1941.

Region No. 11—Allegany, Steuben, Schuyler, Tompkins, and Chemung county medical societies at Elmira on Wednesday, December 10, 1941.

Region No. 12—Erie, Niagara, Cattaraugus, Genesee, and Wyoming county medical societies at Buffalo. This meeting was devoted to a report of a six-year study of the Maternal Welfare Committee of the Medical Society of the County of Erie, held December 17, 1941.

At present arrangements are being made for two Regional Maternal and Child Welfare Teaching Days, one to be held in Albany on April 15, 1942, and one in Rochester on April 1, 1942.

For these Teaching Days, the Committee assisted in arranging for speakers, sent programs to members of the county medical societies, medical schools, hospitals, the NEW YORK STATE JOURNAL OF MEDICINE, the *Journal of the American Medical Association*. The Committee paid the expenses of the speakers coming from outside the regions and the State Department of Health provided honoraria for six speakers participating in these programs.

In addition to this work, a statewide Teaching Day on Cancer was held at Syracuse University College of Medicine, Syracuse, on January 17, 1942, in cooperation with the Tumor Clinic Association of the State of New York and the Division of Cancer Control of the State Department of Health. As its contribution to this Teaching Day, the Committee arranged the publicity, sending notices to all hospitals and medical schools in the state, the *American Journal of Roentgenology*, *Radiology Journal of North America*, *Journal of the American Medical Association*, *Health News*, the NEW YORK STATE JOURNAL OF MEDICINE, and the local press.

The Committee assisted in the arrangements for the first Teaching Day to be held in Industrial Health. This meeting was held in Buffalo on Thursday, February 26, 1942. Notices were sent to the memberships of the following county medical societies: Erie, Niagara, Genesee, Wyoming, Cattaraugus, Chautauqua, and Orleans. Notices were sent to the hospitals and medical schools in the region, and also to the *Journal of the American Medical Association* and the NEW YORK STATE JOURNAL OF MEDICINE. It was regarded as a very successful meeting.

Also, the Committee assisted in the arrangements for the three-day Postgraduate Institute held in Rochester under the auspices of the University of Rochester School of Medicine and Dentistry and the Medical Society of the County of Monroe with the cooperation of the Medical Society of the State of New York. Every attempt was made to cover as wide and as varied a field as possible so that every practitioner of medicine would find something of interest and value.

As a part of the newly inaugurated program on War Medicine and Surgery, the Committee arranged for Dr. Foster Kennedy, professor of clinical neurology, Cornell University, to speak on "Nervous Conditions Associated with War-

fare" at a meeting of the Monroe County Medical Society in Rochester on March 17; Dr. Henry H. Ritter, professor of clinical surgery, New York Postgraduate Medical School, Columbia University, spoke before a meeting of the Onondaga County Medical Society in Syracuse on Tuesday, March 3. The topic of Dr. Ritter's lecture was "Fractures in General—Treatment of Common Fractures."

PART II

Public Health Activities

Certain matters that involve in one way or another the health of the public have been considered by your Council. These have been chiefly in the domain of the Committee on Public Health and Education, but frequently the Committee on Public Relations and Economics and the subcommittees of both have been directed to take part in the studies and in actions based thereon.

Chemotherapy Program.—Preceding the announcement of instruction to be offered in sulfonamide therapy and the speakers available, a two-day conference was held in Albany on October 7 and 8, 1941. Many of the leading authorities in this field addressed this group. An outline was prepared from these presentations to be used by the lecturers who addressed the county medical society meetings and hospital staffs. This is a course of three two-hour sessions arranged by the Council Committee on Public Health and Education and the New York State Department of Health. This course offers an exceptional opportunity to obtain information on the current status of sulfonamide therapy. Since a broad field is covered, every effort has been made to compress it into the shortest possible time and the course can be offered only in its entirety. Although this course focuses attention on chemotherapy, it necessarily covers the general and other special forms of treatment of infections in the fields of medicine, surgery, urology, pediatrics, gynecology, and obstetrics. The sessions may be had either as lectures or clinics. A total of forty-three physicians are listed as speakers in this outline.

Rheumatic Fever.—The Committee on Public Health and Education and representatives of the State Department of Health prepared a list of speakers available for programs for county medical societies and hospital staff meetings. Meetings may be arranged as special single sessions or in connection with formal courses. This announcement appears in the *Course Outline Book*. A considerable number of lectures were given which are listed elsewhere in this report. Commissioner Godfrey, New York State Health Department, appointed an advisory committee on rheumatic fever which gives consideration to many matters including the graduate education regarding rheumatic fever. The physicians who lecture on this subject held a conference to discuss the educational program before it was made available to county societies.

Dental Health.—The Subcommittee on Dental Health prepared an elaborate outline announcing many speakers and subjects available for programs before county medical societies and hospital staffs and this appears in the *Course Outline Book*. In cooperation with the State Health Department and the District Branches of the New

York State Dental Society, three meetings were held in different parts of the state to present the latest information on dental caries. These meetings were held in Binghamton, Rochester, and Albany.

The Joint Committee on Dental Health has the following personnel:

New York State Dental Society—H. Shirley Dwyer, D.D.S., Chairman, 80 Hanson Place, Brooklyn; Leuman M. Waugh, D.D.S., 576 Fifth Avenue, New York City; Charles H. McNeeley, D.D.S., 1 Nevins Street, Brooklyn.

Medical Society of the State of New York—Harry Aranow, M.D., 355 East 149th Street, Bronx; Augustus J. Hambrook, M.D., 40 State Street, Troy; O. W. H. Mitchell, M.D., 428 Greenwood Place, Syracuse.

Industrial Health.—Following the appointment of the committee, arrangements were made for conducting inquiry and postgraduate education in industrial health by appointing a Study Committee. During the year, by conferences and correspondence, much information has been obtained regarding Industrial Health problems and other related activities. A special outline was prepared and included in the *Course Outline Book*. This outline suggested a list of topics and was prepared by Dr. Leonard Greenburg, a member of the Study Committee. Only one session was held in Industrial Health and that was in Buffalo. This meeting was regarded as very successful and was presented under the auspices of the Medical Society of the County of Erie, University of Buffalo School of Medicine, Division of Industrial Hygiene—New York State—Department of Labor, New York State Department of Health, and the Medical Society of the State of New York. The physicians in the following counties were invited to attend this session: Erie, Niagara, Genesee, Wyoming, Cattaraugus, Chautauqua, Orleans. Also invited were physician members of the area of the New York Society of Industrial Medicine, plant nurses, officials from various groups such as the Council of Social Agencies, the Tuberculosis Association, Senior and Junior Chambers of Commerce, labor organizations of the C.I.O. and the A.F. of L. embodying various subdivisions, insurance carriers, the Visiting Nurses Association, the local Health Department, and the New York State Department of Health. The School of Medicine of the University of Buffalo sent its junior and senior students. Later, it is hoped in this area to have an institute meeting, with material to be presented of a general character in which discussion would be participated in by the workers, personnel men, industrial managers, and by physicians.

Study Committee on Industrial Health has the following members: Herbert H. Bauckus, M.D., chairman, 925 Delaware Avenue, Buffalo; Robert K. Brewer, M.D., 865 Livingston Avenue, Syracuse; John H. Garlock, M.D., 50 East 77th Street, New York City; David J. Kaliski, M.D., 50 Park Avenue, New York City; John S. Lawrence, M.D., 260 Crittenden Boulevard, Rochester; Frederic E. Sondern, M.D., 180 West 58th Street, New York City. *Ex-Officio*: Edward S. Godfrey, Jr., M.D., State Department of Health, Albany; Leonard Greenburg, M.D., State Department of Labor, New York City.

Maternal and Child Welfare.—The Maternal Welfare Committee was changed to Maternal and Child Welfare Committee. In addition to the three members, Dr. Charles A. Gordon, chairman, Dr. James K. Quigley, and Dr. Ferdinand J. Schoeneck, a fourth member, a pediatrician, Dr. Alexander T. Martin, was added. In addition to the twelve Regional Chairmen in Obstetrics, twelve Regional Chairmen in Pediatrics were added to Dr. Gordon's committee. An understanding has been reached between the Medical Society of the State of New York and the New York State Department of Health regarding qualifications and compensation for obstetrical consultants. This service will be limited to those patients who, in the opinion of the attending physician, are unable to afford a private consultant. A letter announcing this service was prepared by the Subcommittee on Maternal and Child Welfare and was approved by the New York State Health Department. This letter, which requests each county medical society to submit a list of physicians willing to perform this service, has been sent to the presidents of all county medical societies. Answers to these requests are to be submitted directly to the Maternal and Child Welfare Subcommittee and a report will be made by the chairman, Dr. Gordon. The subcommittee from time to time supplies articles on appropriate subjects for publication in the *JOURNAL*.

Regional Chairmen in Obstetrics:

1. George W. Kosmak, 23 East 93rd Street, New York
New York, Richmond, Bronx
2. Harvey B. Matthews, 643 St. Marks Avenue, Brooklyn
Kings, Queens, Nassau, Suffolk
3. Julian Hawthorne, Highland Hall Apartment, Rye
Westchester, Rockland, Dutchess, Putnam, Orange
4. William M. Mallia, 1364 Union Street, Schenectady
Schenectady, Fulton, Montgomery, Schoharie, Greene, Ulster
5. Joseph O'C. Kiernan, 496 Madison Avenue, Albany
Albany, Washington, Saratoga, Columbia, Warren, Rensselaer
6. Elmer Wessell, 72 Clinton Street, Plattsburg
Clinton, Essex, Franklin, St. Lawrence
7. James L. Crossley, 240 Woolworth Building, Watertown
Jefferson, Lewis, Herkimer, Hamilton
8. Edward C. Hughes, 601 Medical Arts Building, Syracuse
Onondaga, Oswego, Oneida, Madison, Cortland, Cayuga
9. Stuart B. Blakely, 140 Chapin Street, Binghamton
Broome, Tioga, Chenango, Otsego, Delaware, Sullivan
10. Ward L. Ekas, 176 South Goodman Street, Rochester
Monroe, Orleans, Wayne, Livingston, Ontario, Yates, Seneca
11. R. Scott Howland, 531 West Water Street, Elmira

- Chemung, Schuyler, Steuben, Tompkins, Allegany
12. Robert C. McDowell, 50 North Street, Buffalo
Erie, Niagara, Chautauqua, Cattaraugus, Genesee, Wyoming

Regional Chairmen in Pediatrics:

1. Harry Bakwin, 132 East 71st Street, New York City
Manhattan, Bronx, Richmond
2. Charles A. Weymuller, 85 Pierrepont Street, Brooklyn
Kings, Queens, Nassau, Suffolk
3. Reginald A. Higgons, 264 King Street, Port Chester
Westchester, Dutchess, Putnam, Orange, Rockland
4. James J. York, 930 State Street, Schenectady
Schenectady, Fulton, Montgomery, Schoharie, Greene, Ulster
5. Hugh F. Leahy, 176 Washington Avenue, Albany
Albany, Saratoga, Warren, Washington, Rensselaer, Columbia
6. Sidney Mitchell, 71 Court Street, Plattsburg
Clinton, Essex, Franklin, St. Lawrence
7. Norman L. Hawkins, 300 Woolworth Building, Watertown
Jefferson, Lewis, Herkimer, Hamilton
8. Brewster C. Doust, 713 East Genesee Street, Syracuse
Onondaga, Oneida, Madison, Cortland, Cayuga, Oswego
9. John B. Burns, 153 Chapin Street, Binghamton
Broome, Tioga, Chenango, Otsego, Delaware, Sullivan
10. Albert D. Kaiser, 16 North Goodman Street, Rochester
Monroe, Wayne, Seneca, Yates, Ontario, Livingston, Orleans
11. George R. Murphy, 531 W. Water Street, Elmira
Chemung, Tompkins, Schuyler, Steuben, Allegany
12. William J. Orr, 135 Linwood Avenue, Buffalo
Erie, Niagara, Genesee, Wyoming, Cattaraugus, Chautauqua

4-H Club and Youth Activities.—Dr. J. G. Fred Hiss, chairman, is also the Health Director of the New York State N.Y.A. program exclusive of New York City. The chairman of this subcommittee has devoted considerable time and effort to improving the health program among the 4-H Clubs throughout the state. On June 23, 1941, Dr. Hiss addressed the School Physicians Association at Saratoga Springs. At this time attention was called to the health examinations of the 4-H Clubs and the overlapping and reduplication of health programs of youth organizations and the state school system. On August 25, Dr. Hiss attended a meeting of the 4-H State Health Committee at which time he urged that it would be better for the entire state if good physical examinations were made within the school system rather than have all the youth organizations, most of which are composed of school children, try to arrange for complete examination of their members. Acceptance of a

thorough school examination as the standard examination was advocated and the other organizations are requested to aid in having correctable defects corrected. Resolutions adopting suggestions for such a program have been adopted by the State Farm Bureau Federation, the State Federation of Home Bureaus, and the State 4-H Club Federation. The committee decided to discard the old annual health contest because it had very little health value, and has notified the Chicago office that New York State will not participate in the 1942 national health contest on the old basis. The chairman has addressed many groups of youth organization throughout the state during the past year.

War Medicine and Surgery.—In the early part of this year, President Kopetzky discussed with the Committee and the Council the advisability of preparing a list of speakers on plastic and reconstructive surgery and notification of the county medical societies of this program. Such a list was prepared and the county medical societies were notified. Later, when our country became actually engaged in war, another committee to supervise instruction in war medicine and surgery included the plan previously adopted concerning plastic and reconstructive surgery. This subcommittee is organized as follows: The chairman of the Public Health and Education Committee is the chairman of the Subcommittee on War Medicine and Surgery. One representative from each of the following fields has been appointed:

Plastic and Reconstructive Surgery.....	Gustave Aufrecht, M.D.
General Surgery... Frederick S. Wetherell, M.D.	
Orthopaedic Surgery.....	Leo Mayer, M.D.
Neurology and Neurosurgery.....	Byron Stookey, M.D.
Aviation Medicine.....	Louis H. Bauer, M.D.
Internal Medicine... L. Whittington Gorham, M.D.	
Industrial Hygiene... Leonard Greenburg, M.D.	
Epidemiology.....	James E. Perkins, M.D.

Already instruction has begun and it is the plan to provide medical societies and hospital staffs with a list of speakers and a wide variety of subjects.

Venereal Disease Control.—On December 11, at a meeting of the Council, the chairman of the Committee on Public Health and Education reported that the Committee on Public Health and Education considered that venereal disease control in New York State deserves attention of the Council. The following resolution was adopted as the stand to be taken by the Council of the Medical Society of the State of New York. First: That the control of venereal disease requires elimination of commercialized prostitution.

Second: That medical inspection of prostitutes is untrustworthy, inefficient, gives a false sense of security, and fails to prevent the spread of infection.

Third: That commercialized prostitution is unlawful, and that physicians who knowingly examine prostitutes for the purpose of providing them with medical certificates to be used in soliciting are participating in an illegal activity, and are violating the principles of professional conduct of the Medical Society of the State of New York.

A copy of the resolution was put in the JOURNAL and copies were sent to the following federal and state officials: the Secretary of War, the Surgeon General of the Army, the Surgeon General of the Navy, the Surgeon General of the U. S. Public Health Service, the Governor of the State of New York, Commissioner Edward S. Godfrey, Jr., and to Drs. V. A. van Volkenburgh, Edward S. Rogers, and William A. Brumfield of the New York State Department of Health.

Tuberculosis Conference Committee.—On this Committee, operating under the auspices of the state Department of Health, the state department of Social Welfare and Mental Hygiene, the State Charities Aid Association, the Metropolitan Life Insurance Company, and the Medical Society of the State of New York, Commissioner Godfrey, the chairman, on request of the Council, appointed Drs. Mitchell and Hambrook to serve with Dr. Irving. Studies by the Committee have been continued along several lines.

Case finding among contacts, it was agreed, needed to be stepped up to the utmost; and among the methods it became clear that x-ray as part of examination occupies a prominent place. The Council drew up a set of twelve suggestions, which were taken to the Conference Committee soon after the 1941 meeting of the House.

After discussions, the Conference Committee and Council agreed to certain revisions of the original wording of suggestion 10, leaving suggestion 12, however, for future discussion. The suggestions follow as revised:

1. The responsibility for communicable disease control rests largely with government health officials.
2. This responsibility carries with it the necessity of employing and advocating measures known or thought to be effective in disease control.
3. Such measures must be reasonable, without causing hardship, and at a cost which will not act as a deterrent. If the cost becomes relatively great, society must find a way, which is usually sharing cost through government taxation.
4. The per capita cost of x-ray examination for tuberculosis diagnosis is not a financial burden to some people, but to the great majority it is.
5. X-ray examination is necessary as a part of the tuberculosis control program and must be made available.
6. X-ray examination necessitates expensive equipment and specially trained physicians.
7. Patients, who, in the opinion of the health officer or his representative, for various reasons (contacts, etc.) should have a thorough physical examination including x-ray, as a part of the tuberculosis control program, should be rendered x-ray service without direct cost to themselves.

All such examinations should be done only on the written order of the health officer or his representative, or the order of the family physician, and approved by the health officer or his representative. The x-ray examinations are to be made only by

physicians licensed to practice medicine in the State of New York.

8. All x-ray examinations at tuberculosis hospitals and clinics should be done without direct cost to the patients.
9. X-ray examinations, when ordered as a part of the tuberculosis control program by the health officer and performed by a private physician, should be paid for from public funds.
10. No patients, except in emergency, should be examined at tuberculosis hospitals and clinics without approval of the superintendent of the hospital, or the director of the clinic, or on reference by a private physician.
11. In order to prevent lack of service and to encourage active participation of local health units, part or all of the cost of x-ray examinations should be borne through state aid.
12. To avoid misunderstandings regarding interpretation of x-ray findings, techniques and other matters, provision should be made for the establishment of an advisory board on x-ray procedures. Such a board should be composed of radiologists, the majority of whom are in the private practice of medicine. The members of this board should be compensated by, and function as part of, the state Department of Health. (NOTE: Original wording of No. 12 subject to future possible revision.)

During the year, studies of conditions affecting various parts of the state have been made for the committee, with appointment of local committees in a number of places to enlist the aid of all concerned. The program of the parent Conference Committee has been slowly but steadily crystallizing out.

The Deaf and Hard of Hearing

In order to carry on the work started but not finished by the State Commission for the Deaf and Hard of Hearing, President Kopetzky enlarged the Committee of the Society by the addition of four otologists, namely, Edmund Prince Fowler, M.D., C. Stewart Nash, M.D., John F. Fairbairn, M.D., and Ralph Almour, M.D.; A. J. Hambrook, M.D., was continued as chairman of the Committee.

Two meetings of the Committee have been held, at which time a review of the work accomplished was discussed, and the following report was approved by the Council:

REPORT

The State Commission was named with the idea of correcting abuses in the state as far as acoustically handicapped children were concerned. Surveys made several years ago by members of this Committee disclosed thousands of children in the schools of our state who were handicapped by hearing losses. No facilities were available at that time for the early diagnosis and correction of such handicaps. No effort was made to discover such handicaps in the preschool child. Two remedial laws were passed. One was for the reporting of any child with hearing defect, by parent, guardian, teacher, or physician, to the health department. The health department was empowered and directed to give such a handicapped child any and all necessary

treatment. This law if properly enforced would discover, in the preschool age, children with hearing handicaps, would allow necessary treatment, and prevent further hearing impairment. Another law directed especially in the interest of the school child was passed, which required annual hearing tests of all school children. Through the provisions of the Crippled Children's Act, the State Departments of Education, Health, and Welfare, in addition to many private agencies, remedial care is made available to parents who are unable to provide it.

Both these laws have been in the statutes of our state for three years, and have made possible the early discovery of cases and treatment of thousands of children who otherwise would have been neglected. All types of hearing loss, however, are not subject to satisfactory treatment and, in these cases, lip-reading instruction in addition to the regular class work is of paramount importance. This extra instruction makes it possible for the average child handicapped by hearing loss to keep up with the other members of his class. For these reasons efforts were made by the State Commission to pass a lip-reading bill. Last year this bill passed both houses of the legislature, only to be vetoed by the Governor. The bill, Senate Int. 162-Hastings; Assembly Int. 173-C. D. Williams, authorized school district trustees, as well as education boards and union free-school districts, to furnish instruction for physically handicapped children, including remedial instruction, and provided for state aid to help to pay teachers giving such instruction. In his veto the governor said that while he had no objections to the purpose of the bill, and while such corrective and remedial instruction should be extended to all children irrespective of the school they attend, the bill changed in a most important respect the equalization formula under which state aid is extended to public schools. The Committee felt that lip-reading instruction is a necessary aid to the acoustically handicapped child and that efforts should be made this year to have a bill introduced in the legislature to provide lip-reading instruction for all children requiring such aid.

The Committee registered a favorable comment on the appointment of a qualified otologist and the setting up of a soundproof room and installation of a properly calibrated audiometer approved by the Committee in the New York State Workmen's Compensation Department. The victim of an injury rarely has his hearing tested, and the referee is given hearing reports based on a percentage loss of hearing. Tests are taken on all different kinds of audiometers, and the department is asked to act as an official referee and without any precision instrument for guidance. A more accurate and equitable rating for hearing losses was also suggested to the Department of Labor.

Motor Drivers with Hearing Losses.—There is practically no evidence that persons who are partially or entirely deaf cannot drive safely. As a matter of fact a report on deaf-mute drivers, issued by the Department of Motor Vehicles of the State of Pennsylvania, reveals that the 600 deaf-mutes licensed to drive in Pennsylvania are, perhaps, the safest group of drivers in that state. These drivers, as a group, had only one minor accident to mar their record for a period of two years. In a single year 4 per cent of normal

operators were involved in accidents, as compared to $\frac{1}{4}$ of 1 per cent of the deaf. In other words, the deaf drivers were twenty-four times as safe as the so-called normal drivers. This also holds true in New York State. The driver handicapped by hearing defects is more alert than the average motorist, is more self-possessed, has better control in operating his car, and shows a wider knowledge of traffic rules and regulations. He thus compensates for his deficiency in hearing. More careful examinations are required before licenses are issued to such drivers, and a yearly re-check on their hearing is required. Full-length, rear-view mirrors are required in this state for all drivers with hearing defects, and the use of a hearing aid would improve the efficiency of the driver and should be required, just as glasses are required for persons with defective vision.

Hearing Handicaps and National Defense.—The Committee felt that it should continue the study started by the State Commission by making an inventory of the deaf and hard-of-hearing adults in the state and an appraisal of their skills for a national defense program and a study of the training facilities in the defense units for the deaf and hard of hearing, releasing of this inventory to the national defense units of the state and other state agencies. During the last war many skilled workers were released from industry to take their places in our defense forces, and their work was carried on very satisfactorily by individuals with hearing handicaps. As a rule, they are very careful, attentive, and excellent workmen. They are not distracted by ordinary noises and are especially useful in industrial plants where excessive noise is an industrial hazard.

The Use of Hearing Aids.—If lip reading is an aid to the hard-of-hearing child or adult, the addition of a properly fitted hearing aid makes possible the very best use of residual hearing. The same difficulty is found now in popularizing the use of hearing aids as was the case when glasses were first found to be so necessary for poor vision. Personal dislikes as to the appearance of glasses had to be overcome and their need emphasized. The same is true of hearing aids, but even more so. It is almost impossible to prevail upon an individual to wear a hearing aid unless he is old or hearing is almost entirely lost. Residual hearing should be preserved by the use of hearing aids as is vision by the wearing of corrective glasses. The great cost of most hearing aids prevents their use by many people who need them. Good hearing aids made by reliable manufacturers cost from \$150 to \$200. Until the manufacturers can furnish satisfactory models at a cost much less than that prevailing at the present time, their use will be of necessity limited. The Committee will endeavor to take this matter up with the leading manufacturers of hearing aids.

Calibrated Audiometers.—The Committee concerned itself with the question of calibrated audiometers because few are properly calibrated and only one has the approval of the American Medical Association's Bureau of Standards, yet all of them are still on the market. They are very inadequately calibrated, they are not steady or reliable, and what they profess to do on paper, namely, give a fixed standard of measurement like a thermometer, they do not do because they vary. Properly calibrated instruments are required in

order to provide proper hearing aids.

Hearing in Industry.—With the expansion of defense work in industry, it is more than ever necessary to protect men and women in industry whose hearing is liable to be affected by excessive noise, such as that of riveting, boiler making, pneumatic hammers, etc. While all possible noises cannot be eradicated from certain types of work, manufacturers have now perfected noise-softening or eliminating apparatus similar to mufflers on automobiles, and when this is used many of the offensive and injurious noises are eliminated. The committee considered the introduction of legislation making it compulsory in all industries where excessive noise is present for the employer to provide means of any and every kind which would lessen and perhaps obviate the onset of hearing impairment due to trauma from noise. Before such legislation is finally drafted, it is suggested that a conference be held with sound engineers, representatives of industry, trade union officials, and insurance experts, together with the Labor Department and others interested in suitable remedial legislation.

Exhibit at State Meeting.—The Committee has requested and has been accorded space reservation at the meeting of the Medical Society of the State of New York to be held at the Waldorf-Astoria Hotel, April 27 to 30. The latest types of hearing aids and audiometers will be on hand. Information covering facilities for care and treatment of persons with hearing handicaps will be available and specialists experienced in this work will be present to advise all seeking such information. Members of the Committee will participate in the scientific program during the meeting and will furnish articles of information for publication in the JOURNAL and newspapers.

List of Otologists in the State.—The Committee has endeavored to acquire an accurate list of all qualified otologists in the state. Each county medical society has been requested to furnish the names of all its otologists and, further, the president of each county medical society has been asked to name a committee of otologists to work in cooperation with the state Committee. A very favorable response has been received.

Blackouts, Air-Raid Alarms, and the Hard of Hearing.—Several communications have been received by members of the Committee regarding the ability of the hard of hearing to participate properly in air-raid and blackout alarms. Many handicapped by loss of hearing will be unable to hear such alarms and it is suggested that air-raid wardens and organizations concerned with hearing conservation have information as to all such individuals so that necessary aid may be provided. In case of actual damage to property by bombs or fire, this roster will be invaluable in seeing that such people are properly cared for. School children under present regulations will be returned to their homes if alarms warrant such procedure. It is suggested that no cotton or other obstruction be placed in the ears to prevent trauma by noise of bombs or excessive sound. Adults might properly use such protection, but children would be likely to do more damage than good by using them. Local hard-of-hearing groups are asked to meet frequently and keep in contact with defense organizations in each locality, thus providing a maximum of protection. Traffic accidents will increase during such alarms, and the hard of hearing will be required to be

unusually vigilant and observing. The Committee has had active cooperation from the New York League for Hard of Hearing and Miss Estelle E. Samuelson of that organization has graciously consented to act as secretary of the Committee, a position she has held since the Committee was formed eight years ago. Active cooperation is also given by the Empire State Association for the Deaf and all local groups affiliated with this work.

PART III

School Health Program

Your Council, as instructed at the last meeting of the House of Delegates of the Medical Society of the State of New York, has continued "its efforts along the present lines to the end that doctors be put in charge of health and health problems among children of school age, eventually bringing back to the Department of Health the health of our school children, because this is certainly where it belongs, and health education should be continued under the guidance of educators, whether lay or medical."

Your Council reports, with deep dissatisfaction, that the state Department of Education—withstanding further discussions in the last year between representative subcommittees of the Regents' Advisory Council and of the State Medical Society—has shown no disposition to make the basic changes in department procedure that were recommended by the State Medical Society in 1940.

The Subcommittee on School Health of the Council Committee on Public Health and Education is composed of:

F. Christopher Wood, M.D., *Chairman*.
 White Plains
 Albert D. Kaiser, M.D. Rochester
 A. Clement Silverman, M.D. Syracuse

In July, 1941, the subcommittee was invited by a subcommittee of the Regents' Advisory Council to discuss the proposals for changes previously made by the State Medical Society. At that meeting our subcommittee advanced for discussion the following principles, which it divided into three categories: "General," "School Health Service," and "Health Education."

General

"1. The school medical inspection should not be considered or accepted as an adequate substitute for periodic medical examinations and continuous health supervision by the private family physician.

"2. The parent must be brought into the picture. The primary and ultimate responsibility for maintaining the health of the child, for obtaining complete medical and health care for the child, including immunizations and correction of correctable defects, should be squarely recognized and assumed by the parent, assisted where necessary by the duly constituted agencies of public assistance.

"3. While not providing complete medical services, immunizations, or treatment of any kind, the schools should recognize and meet their responsibility of educating parents as to the importance of obtaining adequate and proper medical care, and of informing parents as to where and how such care may be obtained.

"4. The school should cultivate the interest and assistance of the medical profession in the community by recognizing the proper concern and more intimate knowledge of the family physician in regard to the health of the school child, by inviting the active participation and counsel of the profession in the school health program, and by directing those children whose parents can afford private medical care into the hands of the family physician."

School Health Service

"5. In view of the fact that physical education is only a single department or aspect of the entire school health service, the school medical inspector, not the director of physical education, should be the central coordinating factor—the leader and director of the health education and health service program in the school.

"6. The school medical inspector, or school physician, should be paid on a salary basis, and he should be paid enough so that the school may expect him to supervise and participate in the active school health program.

"7. The scope and content of the school health service should be clearly defined and carefully determined with a view to utilizing all related community services and avoiding unnecessary duplication of or competition with such services.

Health Education

"8. The relative functions of the school medical inspector, the director of physical education, the nurse, and the teacher, in regard to health education, should be clearly defined and this definition should be translated into practice."

In addition, our subcommittee submitted a prepared and detailed discussion of each of these principles. Also prepared and submitted were some ten recommendations for specific local and state action, including the recommendation that Section 491 of the Education Law be altered to require that state grants to local school authorities be made on the basis of school enrolment rather than of daily attendance.

Discussion indicated that there was a fair amount of agreement on some of these principles, but there appeared no disposition whatever to accept the principle that the school medical inspector should be the central coordinating factor, the leader and director of the health education and health service program. Despite the apparent general agreement on the majority of these principles, and although it was understood that the Regents' subcommittee would seek further conferences, no request for further discussion has been received by our subcommittee.

The Council feels that this situation indicates an attitude on the part of the Board of Regents of the University of the State of New York against changes in the present school health system—changes which the Medical Society of the State of New York deems essential to better promotion of the health of school children in the State of New York.

PART IV

Publications

The two publications of the Society, the *NEW YORK STATE JOURNAL OF MEDICINE* and the *Medical Directory of New York, New Jersey, and Connecticut*, have been produced in the year 1941 in a manner satisfactory to the Council from both literary and financial points of view.

Journal.—During the year there were published 251 scientific articles—an increase of 22 over 1940. The total number of text pages was 1,899 (including contents and officers' pages). Text content included the following sections: Scientific Papers, Editorials, Correspondence, Medical News (general and county), Book Reviews, Medicolegal, Public Health News, Hospital News, Maternal Welfare (recently changed to Maternal and Child Welfare), Medical Relief, Medical Preparedness, and Mental Hygiene. The scientific sections on Therapeutics and Diagnosis have appeared regularly and will continue to appear. The New York Pathological Society has decided to use another outlet for the reports of its transactions.

The policy was continued of accepting for instant publication timely papers having to do with war medicine and surgery. In some instances it was necessary to postpone publication of some of the scheduled articles.

The use of a new and smaller type for editorial and scientific sections, which was begun with the January 1, 1941, issue, has over the whole year made it possible to publish additional material representing an increase of 200,000 words.

Financially, the Council is pleased to report a marked improvement for 1941. With greater expenses for paper, wrappers, printing of 96 extra pages, and 19,150 more copies made necessary by increased circulation representing more members and more subscribers (each received the 24 issues for the year), the net cost has remained at the low level reached in 1940. This was \$15,847.58 for 1941, as compared to \$15,391.32 for 1940, thus giving a cost per member (calculated on "average" membership for each year) of 88¢ for 1941 as compared to 91¢ for 1940.

It is to be noted, however, that these figures from the auditor's report do not reveal the full picture of financial improvement in production as compared to the previous year. Not only were the extra costs met without corresponding increase in net cost, but a major extra expense was taken care of that implied savings in other departmental expenditures. This result was achieved by allocation to *JOURNAL* expense of substantial portions of the salaries of Dr. Irving, Mr. Anderson, and clerical workers with divided duties. These were bookkeeping entries only, but correspondingly lower salary costs show for the Administration and the Public Relations Bureau. The change in charging salaries according to the disposition of divided services was made in an effort to bring out financial reports truly representative of functional performance of officials and employees. In this fashion it is figured that the *JOURNAL* shouldered \$3,171.77 in the year 1941 as an extra cost.

All the additional expenditures—for paper, printing of more pages and copies, and allocation of salary fractions—were met by larger income

from advertising, and thus the net cost at the same level indicates a real betterment. Actual less cash was expended to produce the JOURNAL in 1941 as compared to 1940, in the sum of \$2,715.51, not counting betterments for more pages and more copies printed.

Directory.—As directed at your last meeting, the 1941-1942 edition of the *Medical Directory of New York, New Jersey, and Connecticut* was prepared in accord with the custom in vogue over the years until the change was tried in the 1939-1940 edition. The listing of physicians by towns was again arranged with Manhattan first, then the other boroughs of Greater New York, followed by the other towns in alphabetical order.

The suggestion that the *Directory* be thumb-indexed for greater convenience could not be followed out because the cost would have been prohibitive.

The financial experience with the 1941-1942 edition of the *Directory* shows improvement in several ways. Even with the added cost of printing 88 more text pages, the net cost was brought down to \$18,096.93 as compared to \$20,010.40 for the 1939-1940 edition, the cost per member being \$1.02 instead of \$1.15, a saving of \$0.13 per member. However, these are the auditor's figures as of December 31 in each year; and a still further improvement will be shown as sales have proceeded since the first of the year. As of February 15, 1942, net income from the sales for the 1941-1942 edition was \$553.31, as compared with \$112.25 net income from all further sales of the 1939-1940 edition; and sales of the present edition are still going on.

For comparative purposes it should be noted also that the improvement in net cost was made in the face of allocation, for the first time, of portions of the salaries of employees with divided duties to the expense of production. This policy reduced by \$2,144.63 the net cost of the Bureau of Public Relations.

Notwithstanding this favorable report, the Council believes it wise, under present circumstances, that consideration be given by the House of Delegates to postponement of publication of the next edition of the *Directory*. At the 1940 meeting the House directed annual publication beginning December 1, 1941.

The Council received the following report from the Publication Committee, dated October 9, 1941:

"In the light of experience gained in the production of the forthcoming edition of the *Medical Directory of New York, New Jersey, and Connecticut* (which will be in the hands of the members the first week in November), the Committee makes the recommendation that the following edition not be published until after the calendar year 1942. The Committee reached this conclusion because of the following reasons:

1. The cost of paper has been jumping rapidly upward and it is difficult to secure deliveries on time—even under existing arrangements for the JOURNAL that were made some time back.
2. The cost of delivery has risen, even for the forthcoming edition of the *Directory*.
3. Three hundred and fifty-five (355) members whose dues were remitted for 1941 have already gone into military or naval service,

prior to June, 1941, and will have no need for a *Directory*. In all probability many more will go into service during 1942.

4. The remission of state assessments for all of these members will necessarily diminish income as compared to what would have been expected under ordinary circumstances."

The Council went on record as follows:

"That in view of unforeseen circumstances and the present economic situation of the Society the opinion of the Council is that a *Directory* for 1942 should not be published until after the House has an opportunity again to assess the merits of this question, it being understood that that would mean a delay of probably six months in the publication of the next *Directory*."

In keeping with this decision the preliminary preparations for the next edition, which in the ordinary course of events would have been initiated in the fall of 1941, have been held in abeyance.

Medical Publicity

Radio.—Following the research work in radio which was described in the report of the Council one year ago, a program series, "Doctors for Defense," was conducted over station WMCA for thirteen weeks in 1941. These programs have been mimeographed and are available at cost to medical societies throughout the country. The titles of the programs are: *Banting: Defender . . . Against Diabetes; Davidson: Defender . . . Against Death from Burns; Minot: Defender . . . Against Pernicious Anemia; Biggs: Defender . . . of the Public Health; Smith: Defender . . . Against Parasite Diseases; Spender: Defender . . . Against Rocky Mountain Spotted Fever; Gorgas: Defender . . . Against Yellow Fever; McCoy: Defender . . . Against Parrot Fever; Goldberger: Defender . . . Against Pellagra; Francis: Defender . . . Against Typhus; Jackson: Defender . . . Through Invention; Park: Defender . . . Against Diphtheria; Jacobi: Defender of the Lives of Children.*

The results of research, and the experience in these broadcasts, have been made available to the membership of the Society as well as those interested in educational broadcasting throughout the country in three bulletins entitled: *The Doctor Takes to the Air; Doctors for Defense; and Radio Commentary on "Doctors for Defense."*

The librarian at Mt. Sinai Hospital requested a recorded transcription of the program devoted to Dr. Abraham Jacobi for the historical files of the hospital. This was supplied.

It was impossible to continue this series permanently because a sponsor satisfactory to the Society and willing to bear the expense of these broadcasts could not be found. The costs to station WMCA averaged \$700 per week; to the Society, for a script writer, an assistant, and incidental expenses, \$100 per week.

But it has been, on occasion, the privilege of the Public Relations Bureau to assist in preparation of other radio material. Most notable in this respect was collaboration with the Columbia Broadcasting System in its half-hour dramatized national broadcast on March 16, *America at Work: Doctors.*

Post graduate Medical Education.—Twenty-one releases regarding institutes and other educational programs sponsored by the Council Committee on Public Health and Education received notices in newspapers in the counties served, as follows: Cayuga, Columbia, Cortland, Delaware, Dutchess, Elmira, Erie, Jefferson, Madison, Monroe, Montgomery, Nassau, Oneida, Onondaga, Oswego, Otsego, Rockland, St. Lawrence, Schenectady, Suffolk, and Tioga.

District Branch Meetings.—All district branch meetings were covered by releases to the daily and weekly press, differing in each instance. Mr. Anderson, director of the Public Relations Bureau, attended all these meetings.

Other Newspaper Releases.—Special releases were issued to the press on the talk by Colonel Samuel J. Kopetzky, M.C., at the meeting of the Monroe County Medical Society, May 29, 1941. Releases were sent to the daily press of the state, to syndicates, and to special departmental editors, on editorials appearing in the JOURNAL for August 1, November 15, and December 15.

Printed Matter.—Reprints of "The Role of the Doctor in Defense," by Colonel Kopetzky, which appeared in the JOURNAL, were sent to a selected list of 5,000 editorial writers, radio commentators, science writers, and health, welfare, and educational publications.

An article entitled "Medical Problems in the Defense Program," by Colonel Kopetzky, was reprinted from the JOURNAL of October 15. This article presented an important interpretation of the significance of selective service statistics, often distorted by persons high in government circles. A total of 25,000 copies of this document was printed. Distribution included health, welfare, and educational publications, dailies and weeklies, libraries, lawyers, clubs, labor unions, farmers, nurses, teachers, and preachers. The Vertical File Service of H. W. Wilson Company, New York City, sent copies to 1,800 public libraries throughout the United States.

An article entitled "The Medical and Social Challenge of Alcoholism" was reprinted from the JOURNAL of December 15, 1941, and mailed to a list of 2,200, including health commissioners, editorial writers, departmental editors, radio commentators, and science writers, in addition to welfare, health-department, educational, and general publications.

Bulletins.—Four bulletins were issued in the Club Talk Series. These were prepared for the Bureau by James E. Bryan, executive secretary, Westchester County Medical Society. They have found high favor among physicians, health workers, and organization and institutional executives throughout the country.

In a letter to the Bureau from Thomas P. Fleming, librarian, College of Physicians and Surgeons, Columbia University, this comment is made on the bulletins of the Public Relations Bureau:

"We have been very grateful to you for sending us your bulletins. They have been extremely useful in a number of ways. With all of the defense activities, many doctors are being asked to speak to small local groups and your Club Talk Series has been particularly helpful to such doctors. Then, too, a number of nurses are giving home nursing courses and the subjects treated in your bulletins and the method of presentation

have been very helpful to such individuals.

"In fact, I may tell you that your bulletins have been so popular that our file is rapidly disappearing. Although at one time our file was complete, the only numbers which we have available are 7, 13, 14, 15, 16, 17, 24, 30, 32, 34, 35, 42, 43, 44. If you could supply us with the missing numbers we would be deeply appreciative."

Titles of the Club Talk Series are: *Fear—the First Enemy of Mental Health*; *Teaching Youth About Cancer*; *It Makes a Difference What We Eat*; and *Progress in Social Hygiene*.

In cooperation with the Committee on Public Health and Education and Dr. Kress of the State Health Department, a special bulletin was issued and distributed. It is entitled *Outline Material on Cancer*.

Other Activities.—Mr. Anderson was elected head of the National Association of Publicity Directors, as chairman of the board for the year 1942-1943.

At the request of Dr. W. W. Bauer of the A.M.A., Mr. Anderson participated in the program on Health Education at the annual meeting of the American Public Health Association, Atlantic City, October 13, 1941. He spoke at the Horace Wells Club annual dinner at Hartford, Connecticut, December 11, 1941. He attended the Conference of Secretaries and Editors in Chicago, November 14, 1941, and the usual meetings of committees of the Society held from time to time throughout the year.

Special assistance was given the Institute for Propaganda Analysis in the preparation of a pamphlet on medical public relations; the *Chicago Tribune* was supplied with information for a feature story; and numbers of individuals, physicians as well as laymen, were assisted in matters relating to medical publicity.

Apparent Expense Increase.—Audits for 1940 and 1941 show expenses for the work of the Council Committee on Medical Publicity increased in the latter year by \$5,544.77. This needs clarification in the light of the situation in the two years. The audit shows that in 1940 the sum of \$15,894.13 was spent, and in 1941, \$21,438.90. To present a true picture of activities, from an administrative point of view, these two years should be averaged, showing an expense for each year of \$18,666.51. This is the reason. In the spring of 1940 demands for public relations work were not so great as usual, and less than the proportionate allocation was spent. In the fall we took over plans to engage in radio broadcasting pursuant to the mandate of the 1941 House of Delegates. Preparatory work was comparatively inexpensive. But when the program got under way, April 9, 1941, expenditures increased sharply. As the project began in the late fall of 1940 and ended the following August, with the chief burden of expense in 1941, expenses for the two fiscal years are thrown out of perspective.

Plans for 1942.—Since the last annual meeting, the United States has gone to war, doctors are being called into service, many controversial issues to which the Public Relations Bureau addresses itself are in temporary abeyance. It is planned to limit expenses for public relations work in 1942, to basic and essential interpretation by the cheapest methods possible, and make a considerable saving on the budgetary allowance.

But it is essential that public relations work be continued throughout the war period. This is necessary to fulfil one of the purposes for which the Society exists, as stated in the Constitution: "To enlighten and direct public opinion in regard to the problems of medicine and health for the best interests of the people of the state."

But continued public relations activity is also advisable for practical and utilitarian reasons. At the conclusion of the war there will be a problem of unemployment the like of which this country has never seen. We shall find fixed upon the social order certain government policies of control over business, industry, and medicine—controls relinquished to the government willingly by the people because of the extremity of military needs, but which will not be ceded back to industry, business, medicine, and the people without a battle for the preservation of individualism. This fight on behalf of medicine can only be waged in the forum of public opinion through a public relations bureau which has not been allowed to languish, but has continued to function, though on a restricted and rationed diet. We should keep up contacts with key persons, retaining the ear of the public and maintaining a mailing list, which will be invaluable in building public opinion at a future time when a public relations bureau may very well be the crucial factor in determining vital issues. There are those who believe that the existence of this Bureau had much to do with delaying the enactment of compulsory health insurance a few years ago; it may very well, at another time in the future, stand the medical profession of New York State in good stead. Artificial respiration can be applied too late. The *alerte* may be sounded without warning.

During the last year or two, Mr. Anderson's services have been increasingly claimed by the Committee on Publications and the Committee on Office Administration. Therefore his activities in 1942 are to be equally divided between this work and public relations.

PART V

Nonprofit Medical Expense Insurance

The Subcommittee of the Council Committee on Public Relations and Economics has continued its work in this field with the same personnel:

Herbert H. Bauckus, M.D., *Chairman*, Buffalo

Walter T. Dannreuther, M.D., New York

William Hale, M.D., Utica

The Council received and approved the following report from the subcommittee.

REPORT

In the 1941 Annual Report to the House of Delegates of the Medical Society of the State of New York, the subcommittee presented a résumé dealing with the formation of plans in New York State and offering a limited analysis and discussion of nonprofit medical expense indemnity insurance. The House in 1941 took appropriate action on certain fundamental questions relating to this form of insurance. The members of the Society are respectfully invited again to consult this report for a better understanding of the subject.

In New York State there are three outstanding organizations operating actively: Medical Ex-

pense Fund of New York, Inc., Brooklyn; Medical and Surgical Care, Inc., of Utica; and the Western New York Medical Plan, Inc., of Buffalo. There are similar groups functioning in various other states, of which the California Physician Service and the Michigan Medical Service are the most widely known.

First of all, it should be plainly stated that the public and the practitioners of medicine stand in no small debt to these pioneers who have so faithfully gone forward in this most difficult task of expanding the avenues of direct medical care. Organized medicine requested this venture; it must follow with greater encouragement and support.

Clearly, the opportune time for selling medical care policies to the indicated economic stratum is at hand. At all times we have had the responsibility of safeguarding the health of our American workers and their families. In times of war, however, when their productive capacity and their morale are worth so much to the achievement of victory—and victory worth so much to the world—we have a far greater stimulation to our zeal, our service becoming a privilege inspired by the love of country. What the war and the price of liberty will cost our people no one can foretell, but all medical authorities are already deeply concerned with the oncoming peril to life and health.

At the present wage level, the worker has the means to buy medical indemnity insurance. He will buy the right kind of policy at the right price when he becomes educated to the benefits of budgeting for health. It should be remembered that the recent rise in wages is somewhat counteracted by the increases in the cost of living, by increased taxation, and the paying of debts contracted in previous years. It is not likely that the existing earning opportunities will continue indefinitely, but if we can make regular saving for the cost of medical care a habit with the worker, we may be sure that he will make every effort to continue his protection when employment becomes less remunerative.

The time and the tide being thus ripe, why the limited success in enrolling large numbers of people in the existing plans?

There are, no doubt, shortcomings in the plans as they stand today, and we hope that these will be evaluated and faced squarely by the local groups themselves. Looking toward the future, we present the following for consideration:

1. Educate the individual and the community to the great value of preventive medicine and early medical care. Insist that the official public health agencies increase their educational efforts by means of circulars, the radio, and the press. Make genuine and alive the often repeated statement that "the health of the people is the first concern of the government" by insisting that there be a physician as Secretary of Health in the Cabinet of the President of the United States. Public opinion should most heartily support this idea for the comfort and health of future generations. Institute health programs, emphasizing especially child health and industrial hygiene. Meet the layman on common ground of informed understanding. Ask for, and provide, lay help in educational programs.

2. Point out the importance of periodic and

regular health examinations. Prepare in the plans an examination system that will be satisfactory and thorough.

3. Provide good medical care, and prevent the lowering of modern standards by an adequate fee system, following in the main the Workmen's Compensation fee schedule of the Department of Labor of New York State. The cost of living of physicians is rising, too. The public would quickly associate inadequate fees with inferior service.

4. Build your plans chiefly on large groups, so that large numbers and unweighted samples are substituted for selective risks. This will allow minimum premiums, greater coverage, and should lead to the elimination of the troublesome deductible fee or coinsurance clause.

5. Do not exclude important catastrophic diseases, such as tuberculosis, syphilis, and other infectious diseases which constitute a great public health hazard.

6. Provide within the plans facilities for laboratory and x-ray service when they are necessary for proper diagnosis and treatment.

7. Keep the premium rate low enough first to provide the lower income groups with adequate and complete medical care for every insurable illness of a serious and catastrophic nature; and add specialized services as the plans will bear them. A desirable policy, widely sold, will soon furnish a cushion for additional service and possibly for a service to the unemployed. The cost of any plan should be estimated with the accessibles of a community in mind rather than with the thought of "how can we manage at this price?" If an area of 750,000 inhabitants has an insurer potentiality of 150,000 organized men and women workers (excluding their families), this figure should serve as a guide to determine the maximum cost to the consumer based on a minimum number of participants necessary for the fullest medical coverage. Such an attitude will change our entire approach to the selling of the plan and other administrative problems.

8. Institute educational and sales projects within the membership meetings of the workers. We are an organized profession—let us recognize other worthy organizations.

9. Secure consumer participation by inviting rank and file representation to the membership of Boards of Trustees of medical indemnity plans. Encourage physician participation in education and promotion.

10. Devise practical methods for a closer welding of publicity and sponsorship from lay community groups.

11. Sell medical indemnity insurance independent of hospitalization insurance plans. In many ways they differ greatly.

12. Give careful and well-studied consideration to the formation of a State, or an American Medical Association, plan for nonprofit medical expense indemnity insurance. Such a plan would have to be quite flexible and easily adaptable to local conditions. Its development, which should possibly be started this year, would undoubtedly encourage the formation of additional prepayment plans.

It might be well, at this point, to draw a few comparisons between medical indemnity insurance and any other type of insurance, be it life, fire, automobile, or even hospitalization insurance. A casual glance at the underlying principles in any of the above-mentioned schemes will clearly show the fundamental difference between these and medical indemnity insurance. Broadly speaking, we can say that all four types have a very wide spread of coverage, with payment for losses usually only once and after long periods of premium payments. All four are carried and sold with the expectation that they will not have to be called upon. Medical indemnity insurance, however, is sold and bought with the clear understanding that every individual has some signs and symptoms each year which should be attended to, and for which the policy should be utilized. Moreover, by advocating better and more complete preventive medicine, medical indemnity insurance plans invite the insurer to the fullest use of his policy.

If we understand these differences we will free ourselves of a good deal of mechanical thinking usually associated with the word "insurance." Adjustments on the part of both doctor and patient will be made more readily, the financial features will take second place after service, and a desire will grow among all parties concerned to make the plans function well.

It has been said that medical expense insurance has been approved by the organized medical profession because it was on the defensive against proposed legislation for compulsory sickness insurance. Those of us who sincerely strive to better our cooperation with public welfare groups will give little heed to such statements except in remembering that the American public has always been able to see that political medicine is not good medicine.

It is a curious phenomenon that all through the years the progressive physician has been forced to fight for humanity in the false and unpleasant light of a defendant of his own interests. To protect our people from the charlatan, the sorcerer, and the quack, from the inadequately schooled, the untrained, and the inexperienced, from the commercial-minded exploiter of misery and the symptom-monger of the present day, the medical profession has ever and anon—and often alone—fought legislation which it believed to be bad, solely in the interest of its lay brother.

The winning of the war has become a unanimous desire in the minds of our people. The worker in industry is proud of his responsibility in helping to win the war. He will want to do everything in his power not to jeopardize this responsibility. He will be eager to do his share in protecting himself and his family against sickness, and if once he has known the benefits of this protection he will never again want to relinquish them. He will learn to see health as the most important part in his budget next to food and shelter. He will sacrifice for this protection, even when the wave of higher earnings has subsided.

In closing this report, your Committee wishes to state its sincere belief that in providing nonprofit medical expense indemnity insurance plans the medical profession is hopefully building for the future of the American people.

PART VI

Medical Relief

The Council has continued the same Subcommittee on Medical Relief, working under the Committee on Public Relations and Economics:

E. Christopher Wood, M.D., *Chairman*.....
 White Plains
 Carlton E. Wertz, M.D..... Buffalo
 F. Leslie Sullivan, M.D..... Scotia

The Council transmits the following report of the Subcommittee, with its approval.

REPORT

At the last meeting of the House of Delegates, in April, 1941, your Subcommittee on Medical Relief presented a detailed report* of its discussions with the State Department of Social Welfare with respect to several Principles previously adopted by the House of Delegates to govern working arrangements between the medical profession and the Departments of Public Welfare. Included in the 1941 report were: a detailed enumeration and discussion of each of these principles; a statement of the basic policies essential to the establishment of a satisfactory local medical care plan; and a Joint Statement, indicating and explaining in detail the general background of the existing methods of providing medical care, and emphasizing throughout the central role the physician and the local medical society should play in determining medical needs and making plans to meet them.

Conferences and discussions have continued during the past year, and the following Joint Statement is an attempt to evaluate progress made in providing medical care to the needy, under the Principles upon which agreement was reached.

Joint Statement

*From the New York State Department
 of Social Welfare and the Medical
 Society of the State of New York*

Local Medical Care Plans
in the State of New York

"As of March 15, 1942, an approved local medical care plan had been adopted or was in course of active preparation in Social Welfare Departments in twenty-two counties and five cities in New York State—an area embracing more than three-fourths of the total population—to make available necessary medical care to at least 578,000 needy men, women, and children.

"In New York State, exclusive of New York City, local medical care plans were approved and in operation in fifteen counties and two cities, covering some 80,000 persons or more than one-third of the total number of recipients of public assistance, and such plans were in active development in seven additional counties and two cities embracing 46,000 more persons—so that about one-half of the persons receiving public assistance outside of New York City have, or will soon have, available to them a comprehensive medical service, adapted to local medical needs and facilities.

"New York City, with a medical care program peculiarly its own, is also developing a local medical care plan to conform with our basic policies. The 452,000 persons in New York City in receipt of public assistance comprise more than three-fifths of the total public assistance case load in the State—so that, although there are thirty-four counties and forty-five cities in the state with no local medical care plan under development, these seventy-nine remaining public welfare districts represent less than one-fifth of the total of 714,443 persons receiving public assistance in the state in January, 1942. These districts continue to render medical care to the needy under the rules and regulations of the State Department Medical Manual.

"Initiation of Local Medical Care Plan.—Complete freedom of action on the part of the local welfare district prevails in the initiation and adoption of an approved local medical care plan. A commissioner of public welfare can either continue to operate within the general restrictions of the *Manual of Medical Care*—which means continuing state review of certain medical problems—or take steps to prepare a tailor-made medical care plan for his community specifically designed to fit its special needs and special resources, a plan which, if approved as to basic policies, would make possible complete local control, both medical and fiscal.

"Preparation of a local medical plan usually takes the following course. (1) There is increasing concern on the part of the public welfare official with the problems of medical care, since, as large numbers of the physically fit become employed and self-sustaining, a higher percentage of persons still receiving public assistance is unemployable because of physical defects, poor health, and illness. (2) It is noted that a disproportionate amount of total welfare expenditures is for medical and hospital care. (3) Since much of this cost involves hospital care, which in the main is not reimbursable, the public welfare official seeks the advisory and consultation service offered by the State Department of Social Welfare in the formulation of a complete local medical care plan.

"The first step in the formulation of this medical plan consists in the preparation of a two-year summary of all expenditures, for medical, dental, and nursing services, hospital and convalescent care, drugs, medical supplies, and prosthetic devices—made under existing arrangements. This is analyzed for completeness by an area medical social worker, who then proceeds to compile a complete inventory of all medical and health facilities and services, both public and private, available in the community. She then makes a careful record and analysis of all the procedures and methods through which medical care is provided, following a request for any item of such care. Then both the inventory of facilities and the analysis of procedures are discussed with the public welfare official in the light of their relationship to the basic policies and procedures which are the minimum essential for the adoption of an approved local medical care plan. Since these basic policies are sufficiently broad to permit an infinite variation in detail to meet special local problems and needs, the initial draft of the local medical care plan is frequently revised from two to six times before

* See "Medical Relief: Joint Statement," New York State J. Med., 41: 619-624, No. 6 (March 15) 1941.

it is considered satisfactory to all the participants in the plan.

"In the consideration of local problems and the various possible alternative methods of providing medical care, the advice and guidance of local medical societies are invaluable, and the labor of preparing a plan is made immeasurably more easy when such cooperation is willingly given.

"Scope of Local Medical Care Plan.—An approved local medical care plan may provide for all forms of medical care, including many or all of the following:

- Acute illness, home or office
- Ambulance service
- Boarding homes for invalids
- Chronic illness, home, office, etc
- Clinic care, by referral
- Consultant services
- Dental care, including
 - Prophylaxis, Treatment, Fillings, Extractions, Dental surgery, Dentures
- Drugs, sera, etc.
- Eye examinations
- Eyeglasses and glass eyes
- Fractures
- Hospital care
- Laboratory services
- Major surgery, home or hospital
- Medical services in hospital
- Mileage (zoning basis)
- Minor surgery
- Nursing care, including
 - Visiting nurse, per visit
 - Registered nurse, per day
 - Practical nurse, per day
 - Home medical aides
- Nursing home care
- Obstetrics, home or hospital
- Physiotherapy
- Pneumonia treatment
- Preventive services, by referral
- Prosthetic or surgical appliances
- Radium treatment
- Sickroom supplies
- Specialist services
- Tuberculosis treatment, home
- Venereal disease treatment
- X-ray diagnosis
- X-ray treatment

"It should be recognized that while all of these items of medical care can come within the scope of Section 184 of the Social Welfare Law as a responsibility of the local welfare district, state reimbursement for some expenditures is not available because of *specific legal restrictions* or exclusions.

"General Impressions and Summary.—Good medical care can be made available to meet the medical needs of the individual, on a simple and efficient basis, under an approved local medical care plan. Since the local plan is designed to meet special local problems and needs, it can be changed to meet new problems and needs. An opportunity is given for participants in the medical plan, e.g., physician, dentist, nurse, hospital superintendent, etc., to take part in the formulation of the local plan and to submit to the public welfare officer or his medical director suggestions for correction, amendment, or improvement in the method or terms under which

services or supplies are provided. For example, if one or more physicians in a community operating under or preparing for an approved local medical care plan feel that the policies and terms of the plan are unreasonable, they should not criticize the plan without first submitting their comments for proper consideration by the public welfare official.

"The commissioner of public welfare has a dual responsibility in the development and operation of a medical care plan: (1) he is responsible for providing necessary medical care for persons under his care; and (2) he is responsible for an economical administration of medical expenditures, to permit him to provide all the other necessities of life for such persons within the total appropriations of tax funds made to him.

"The welfare official, both state and local, must consider as a resource any state or federal funds which may be available to him, under existing statutes. It was for this reason that representatives of the Medical Society of the State of New York agreed "to go along" with a "direct payment plan"* which would require certain patients to pay physicians directly for authorized medical care. This plan made possible participation by both the state and local welfare departments in federal funds made available under the Social Security Act. The experience with this plan to date indicates that patients fail to pay physicians for authorized services only in a negligible number of cases.

"The program leading to installation of approved local medical care plans gives an opportunity to each community to adopt and assume full local responsibility for providing good medical care to needy persons in the community—with full recognition given to special needs and special resources. Physicians, welfare officials, appropriating bodies, and all others interested are urged to continue their support of this program, which has shown that it can integrate and correlate all of the medical care services which are provided in a community at public expense."

CHRISTOPHER WOOD, M.D., *Chairman*,
Subcommittee on Medical Relief, Medical
Society of the State of New York
LEE. C. DOWLING, *Deputy Commissioner for*
Public Assistance
H. JACKSON DAVIS, M.D., *Chief Medical Officer*,
State Department of Social Welfare

PART VII

Legislation

The Council Committee, charged with the duty of studying legislation and putting forth the positions taken by the Society, was continued with the same personnel:

John L. Bauer, M.D., *Chairman* . . . Brooklyn
Walter W. Mott, M.D. . . . White Plains
Leo F. Simpson, M.D. . . . Rochester

The Committee makes the following preliminary report as of March 7, 1942. A supplementary full report will be ready for the House on April 27, 1942.

* See "Medical Relief for the Aged, the Blind and for Dependent Children," New York State J. Med., 41: 1006, No. 9 (May 1) 1941.

REPORT

Many of our legislators are on the job the year around. Those who are lawyers may be associated as counsel to business and industry, seeking a certain amount of favorable legislation. This legislation may be introduced by the lawyer himself—or he may interest another legislator, not necessarily a lawyer. These legislators may exchange courtesies—and strengthen and support the efforts of each other. It may be clever to favor or disapprove a bill in one body, knowing that others will offset the action in the other body. There may be nothing vicious in such procedures. The legislators may not sufficiently understand the import and far-reaching effect of the particular bill, in the pell-mell rush of legislation; they may be pledged to vote to please a friend.

It is our business to inform the legislators so that they shall be able to act intelligently and conscientiously on the bills which concern the welfare of the people from a health standpoint. We know that the lawyer may be influenced by the fact that some judge has mistakenly decided that x-ray diagnosis is not the practice of medicine, or by some other similar court decision. We should guide our legislators; if we do, we shall find them rather responsive.

We have a trust, and we as doctors realize and appreciate that trust. We may share that trust with the legislators by having them understand our attitude. The health interests of the people, of today's patients, of tomorrow's sick, must be protected. So we attempt and favor beneficial legislation and we try to block baneful legislation. We must interpret bills for them.

It was all very well to set up physiotherapists, mostly veterans of the first World War. We do feel that we owe a great deal to the veterans. But the restrictions were wise—the diagnosis and prescription for the kind and amount of modality to be given by a physician. These restrictions are beneficial to veterans and their families as well. The law has been disregarded—rarely is the doctor consulted. Generally, the physiotherapist treats as he will, without the formality of diagnosis and prescription. In conference with them and their counsel, Judge Dyer, we learned that they feel competent to diagnose and treat. So, in their new bill they are asking to practice medicine, and the legislators, if properly advised, will not permit it.

Each year, the doctors pay a registration tax, the monies to be used to enforce laws to prevent charlatans and quacks from their injurious practices. The physicians should not be required to provide for this service, except as citizens—and all citizens for the common good should provide the costs. In other words, sufficient money should be employed, taken from the general tax funds. At present it is a class tax, unfair, insufficient in amount; therefore only feeble and almost futile attempts to enforce laws can be made.

Those known as chiropractors are practicing illegally in New York State. The law should be enforced against them. We are yearly asked to appease these men—to pacify them by taking some of these illegal practitioners and giving them recognition, setting them up as a board of experts, legalizing them to examine and qualify the others. Scientists declare there is no scienti-

fic value in chiropractic. The chiropractors are busy in Washington. They are petitioning Congress for the right to treat federal employees, under the Federal Compensation Act. If this Tolan bill be successful, it might well be the slogan for the struggle in New York State. We refer to the Assembly Bill—Brees—No. 1434.

The practice of chiropractic as herein defined is hereby declared not to be the practice of medicine, within the meaning of the laws of the State of New York defining the same.

A second entering wedge! The first happened through a decision made once upon a time by a judge that the use of x-ray is not the practice of medicine. So when we desire to safeguard the interests of the people in their health, we find we are seriously opposed by the chiropractors—for x-ray diagnosis is the practice of medicine—and only one fully qualified to practice medicine can make such diagnoses correctly. Hence, the chiropractor may not use x-ray and loses his first entering wedge.

Many physicians in the State of New York are following, in this spirit, the bills introduced in the legislature, as well as federal legislation. We are aware of certain proposed federal legislation which would be inimical to the Associated Hospital Fund and the like. We are aware that the Hampton Bill is, on the other hand, the product of a certain well-known sponsor of the Associated Hospital Fund, seeking a change in the law which we all worked so hard for—the law that prevents any corporation from issuing combined contracts for both hospital service and medical expense indemnity.

Our executive officer, Dr. Joseph S. Lawrence, has a bureau of newspaper clippings which proves very valuable in our work. Late last spring and during the summer, Dr. Lawrence was busy with correspondence with the other states, learning all about the chiropractic laws and schools and boards; and obtaining letters from prominent scientists as to their opposition to the chiropractors. Some of us have copies of all of this material and lately he has had mimeographed, in quantities, these letters from the scientists, so that Congressmen and legislators may be thoroughly informed.

We need not enumerate or describe the many bills concerning automobile drivers' licenses, compensation, hospitals, health questions, labor problems, expert medical witnesses, malpractice, nurses' registers, x-ray, State medicine, Medical Grievance Committee, life insurance, etc.

The Annual Conference of County Society Legislative Chairmen was held at Albany, on Friday, February 20, 1942, and a very earnest, well-informed, actively participating and enthusiastic group was present. Thirty-nine counties, one more than last year, had representatives. All the bills to date were carefully considered and acted upon, a fine testimony to the successful methods employed by our executive officer.

The nurse training school problem was introduced and a method of procedure for later consideration and action was given to those most interested. Welfare problems were referred to the proper committee. Conferences during the year have been held with senators, assemblymen, doctors, lawyers, judges, and laymen.

To Dr. Douglas Quick and others of the New

it is considered satisfactory to all the participants in the plan.

"In the consideration of local problems and the various possible alternative methods of providing medical care, the advice and guidance of local medical societies are invaluable, and the labor of preparing a plan is made immeasurably more easy when such cooperation is willingly given.

"Scope of Local Medical Care Plan.—An approved local medical care plan may provide for all forms of medical care, including many or all of the following:

- Acute illness, home or office
- Ambulance service
- Boarding homes for invalids
- Chronic illness, home, office, etc.
- Clinic care, by referral
- Consultant services
- Dental care, including

- X-ray treatment

"It should be recognized that while all of these items of medical care can come within the scope of Section 184 of the Social Welfare Law as a responsibility of the local welfare district, state reimbursement for some expenditures is not available because of *specific legal restrictions or exclusions*.

"General Impressions and Summary.—Good medical care can be made available to meet the medical needs of the individual, on a simple and efficient basis, under an approved local medical care plan. Since the local plan is designed to meet special local problems and needs, it can be changed to meet new problems and needs. An opportunity is given for participants in the medical plan, e.g., physician, dentist, nurse, hospital superintendent, etc., to take part in the formulation of the local plan and to submit to the public welfare officer or his medical director suggestions for correction, amendment, or improvement in the method or terms under which

services or supplies are provided. For example, if one or more physicians in a community operating under or preparing for an approved local medical care plan feel that the policies and terms of the plan are unreasonable, they should not criticize the plan without first submitting their comments for proper consideration by the public welfare official.

"The commissioner of public welfare has a dual responsibility in the development and operation of a medical care plan: (1) he is responsible for providing necessary medical care for persons under his care; and (2) he is responsible for an economical administration of medical expenditures, to permit him to provide all the other necessities of life for such persons within the total appropriations of tax funds made to him.

"The welfare official, both state and local, must consider as a resource any state or federal funds which may be available to him, under existing statutes. It was for this reason that representatives of the Medical Society of the State of New York agreed "to go along" with a "direct payment plan"* which would require certain patients to pay physicians directly for authorized medical care. This plan made possible participation by both the state and local welfare departments in federal funds made available under the Social Security Act. The experience with this plan to date indicates that patients fail to pay physicians for authorized services only in a negligible number of cases.

"The program leading to installation of approved local medical care plans gives an opportunity to each community to adopt and assume full local responsibility for providing good medical care to needy persons in the community—with full recognition given to special needs and special resources. Physicians, welfare officials, appropriating bodies, and all others interested are urged to continue their support of this program, which has shown that it can integrate and correlate all of the medical care services which are provided in a community at public expense."

CHRISTOPHER WOOD, M.D., *Chairman*,
Subcommittee on Medical Relief, Medical
Society of the State of New York

LEE. C. DOWLING, *Deputy Commissioner for
Public Assistance*

H. JACKSON DAVIS, M.D., *Chief Medical Officer*,
State Department of Social Welfare

PART VII

Legislation

The Council Committee, charged with the duty of studying legislation and putting forth the positions taken by the Society, was continued with the same personnel:

John L. Bauer, M.D., *Chairman*.....Brooklyn
Walter W. Mott, M.D.....White Plains
Leo F. Simpson, M.D.....Rochester

The Committee makes the following preliminary report as of March 7, 1942. A supplementary full report will be ready for the House on April 27, 1942.

* See "Medical Relief for the Aged, the Blind, and for Dependent Children," *New York State J. Med.*, 41: 1006, No. 9 (May 1) 1941.

Only specialists, or those between the ages of forty-five and fifty-five whose experience fits them especially for military duty, will be called to the armed forces.

Women physicians are not commissioned in the military service. Certain of the government agencies—the Office of Civilian Defense; Industrial, State, and Public health agencies—will both need and utilize the services of women. As the need develops they should be encouraged to take on such additional duties as would make available for military service physically fit male physicians.

Part-time Service.—Individuals may not be considered essential who have part-time participation on a Health Department staff, in teaching, or in other capacities; but total time spent in these capacities would identify them as being essential. Wherever possible, persons over forty-five or those disqualified for military service should be encouraged to take on such part-time positions as will assist in releasing others for military service.

These are, in essential, the formal rules governing the processing of medical men whose status comes before our Committee.

The even flow of doctors through the medical schools into the internships and then into the armed forces has been established. Only when individual physicians, either through apathy, ignorance, or unwillingness, fail to conform with published regulations does individual hardship develop, and this, at times, the Committee is able to mitigate.

It would take this Committee too far afield to detail all the pertinent questions with which we are continuously employed. There are thousands of individual questions. All have had attention.

This Committee has no recommendations at this time. It wants to report its deep indebtedness to Dr. Peter Irving, whose continuing work with us has made our activity possible. Had he not taken on this work, some full-time executive secretary would have become a necessity. The correspondence has been handled by Miss La Porte of the office force. This young woman, handling much detail without regard to long hours, has been a faithful worker in our ranks. She deserves our sincere thanks.

Finally, the thanks and appreciation of the Committee are given to the secretaries and the chairmen of the component Medical Preparedness committees of the county societies. The cooperation has been splendid.

There is being established a National Roster of Physicians by the Washington Headquarters of the Selective Service. The application blanks are now pouring into state headquarters. This roster of physicians and dentists is to be used to give medical care to *rejected registrants* with remedial physical defects. The rehabilitation program has not yet been put into effect in this state. We shall have considerable concern with the manner in which this program proceeds. In the interest of completeness, it needs inclusion in this report. It comes within the framework of our activities if it will add man power to our armed forces. If the program, on the other hand, is a service to procure medical care to the population generally, this Committee has no legitimate concern with it, and the projected activity will

fall into other hands for its supervision and control.

The chairman of the Committee has not dilated upon his visits to county societies and his attendance at numerous conferences—in New York City, in Albany, in Chicago, and in Washington—or upon his contacts with agencies of government both in the metropolitan area and in Albany. These conferences were necessary in the interest of the physicians of the state.

PART IX

Workmen's Compensation

The Council Committee on Workmen's Compensation, Dr. Clarence G. Bandler, New York, *chairman*, Dr. Joseph C. O'Gorman, Buffalo, and Dr. David J. Kaliski, New York City, also director of the Workmen's Compensation Bureau of the Society, has presented the following report which is submitted with approval of the Council:

REPORT

Up to the present time nearly 19,500 physicians have been qualified by the county medical societies' compensation committees throughout the state. Two hundred and ninety-six physicians have been qualified by the New York State Homeopathic Board and about 360 physicians by the compensation board of the Osteopathic Society, making a grand total of 20,000 physicians qualified to practice under the Workmen's Compensation Law. This represents over 90 per cent of the practicing physicians of the state.

The number qualified in each county follows:

Albany, 299; Allegany, 42; Bronx, 2,038; Broome, 217; Cattaraugus, 82; Cayuga, 69; Chautauqua, 109; Chemung, 100; Chenango, 41; Clinton, 47; Columbia, 42; Cortland, 43; Delaware, 52; Dutchess, 152; Erie, 998; Essex, 35; Franklin, 67; Fulton, 67; Genesee, 54; Greene, 43; Herkimer, 58; Jefferson, 108; Kings, 3,580; Lewis, 23; Livingston, 55; Madison, 40; Monroe, 528; Montgomery, 61; New York, 5,081; Nassau, 520; Niagara, 168; Oneida, 234; Onondaga, 409; Ontario, 101; Orange, 159; Orleans, 29; Oswego, 74; Otsego, 66; Putnam, 16; Queens, 1,247; Rensselaer, 131; Richmond, 129; Rockland, 92; Saratoga, 70; Schenectady, 116; Schoharie, 30; Schuyler, 12; Seneca, 27; Steuben, 88; Suffolk, 195; Sullivan, 70; St. Lawrence, 91; Tioga, 39; Tompkins, 70; Ulster, 109; Warren, 57; Washington, 50; Wayne, 67; Westchester, 763; Wyoming, 44; and Yates, 27.

Character of Medical Care.—Under Section 13-b of the Workmen's Compensation Law statutory authority is given to the compensation boards to recommend physicians for authorization. It should be noted that the authority under the Law indicates that the Medical Society shall specify the *character* of the medical care which a physician is qualified and authorized to render. This may be interpreted as meaning that it is within the power of the compensation boards, subject of course to review by the Industrial Council, to indicate the scope and range of a physician's practice. It was the intent of the Law to place upon the medical societies this

York Roentgenological Society, we are greatly indebted. Mr. Cahal of the American Association of Radiologists is included. To the Woman's Auxiliary is due our thanks for their general aid and for the wonderful service of their legislative chairman, Mrs. Madden of Albany, who has visited many of the District Branches and explained legislative procedures and the meaning of the bills. The officers, the Council, and various chairmen have met with us on several occasions and given to us their valuable opinions and advice.

PART VIII

Medical Preparedness

The Council transmits with approval the following report of its Committee on Medical Preparedness, which is as follows:

Samuel J. Kopetzky, M.D., *Chairman*..... New York
Edward T. Wentworth, M.D..... Rochester
Louis H. Bauer, M.D..... Hempstead

REPORT

This Committee, set up by the Council during the previous year, when the nation's slogan was "Preparedness," has functioned with the same chairman and personnel ever since. It early established working relationships with, and encouraged the establishment of, medical preparedness committees in all the component county societies.

The Mailer Legislative Committee on Health Preparedness of the state was functioning for the purpose of coordinating all the medical and ancillary forces in one effort to prepare the State of New York for defense. Your Committee on Medical Preparedness associated itself with this state agency in a mutually cooperative effort. This has continued.

Thereafter ensued the passage of the Selective Service Law. Under its provisions, and under authority of Governor Lehman, this Committee, after clearing the names of such medical personnel, nominated to the Governor for appointment by the President of the United States all the examining physicians of two hundred local boards in upstate New York, and two hundred and fifty local boards in the New York City area. In addition, names of physicians were nominated to the Governor for appointment by him to all the Medical Advisory Boards of the state. Finally, at the request of the Governor the names of specially selected physicians were forwarded to serve him as members on Appeal Boards of the state.

The Surgeon of the Second Corps Area turned to this Committee to furnish the medical section of the Recruiting Office of this military area with the names of physicians, in various specialist categories, to serve as specialists on the various Second Corps Area Army Induction Examining Teams.

To accomplish the integrated medical service there was needed rapid, considered action. Every component part of the Medical Preparedness Committee functioned adequately and efficiently, and the Medical Section of the Selective Service Law has had compliments and approval from all authorities concerned.

Then came the War. The Mailer Commission

took on added functions in an all-out effort to win the war. The Medical Preparedness Committee also intensified its activity. The work has been exacting and has required daily attention. It necessitated a large correspondence. The files which had been collected in cataloging the medical profession of the state have been a valuable aid in estimating the medical men of the state.

The armed forces of the nation, the civilian defense service, and many other governmental medical services require doctors. In the effort to spread the available medical talent where it may be most needed, there has been set up, by Presidential Executive Order, a Procurement and Assignment Service to accomplish this purpose. Your chairman of this Committee has been named as the New York State Chairman for Medicine. Dr. Arthur W. Booth, of Elmira, was designated as the General Chairman of the Second Corps Area. He correlates the activities of the state chairmen for medicine—Dentistry, Veterinary Medicine, Education, Hospitals, etc.—for the states of New York, New Jersey, and Delaware. This constitutes the entire setup with which this Committee functions. The organization of the Procurement and Assignment Service is in process of being further organized. Clerical help has not yet been supplied. This was to be furnished from the Regional Social Security Board. There is full realization that this service will shortly be properly provided for. In the meantime, the Medical Society of the State of New York is carrying the financial burden of supplying clerical help, costs of postage, and telegrams.

The above constitutes the machinery within the framework of which we function.

Our aim now is to further the war effort. To this end we are constantly on guard to conserve medical man power, to see to it that physicians are not inducted into the Army as soldiers but are deferred by Selective Service boards until they are commissioned as medical officers, or held as unavailable for military duty and assigned to duty in some other federal governmental agency. Rules of procedure in processing these medical men have been published, and should be better known.

Under Forty-five Years of Age.—The Selective Service Act makes all men under forty-five available for military service. Procurement and Assignment headquarters suggests, therefore, that all men *below* the age of forty-five should be, in the main, listed as available. This, of course, cannot be adhered to strictly. The desirability of establishing the necessity of deferment from military service rests upon the individual and upon *his* employing agency.

In case military demands require the assistance of any man under the age of forty-five and he is considered essential in his community, an attempt should be made, if possible, to arrange for a replacement. Those classified as essential in their communities should include predominantly physicians under forty-five years of age who are physically disqualified for military service, women physicians, and research assistants.

Above Forty-five Years of Age.—The majority of persons considered essential in the community should belong to this age group.

does not strictly limit his practice to a specialty or where he has not yet had sufficient experience, although well trained, to be granted the full specialist's or consultant's rating. However, even the XA or XB, etc., rating is not given unless the physician can establish the fact that he is qualified in his special branch of medicine by reason of education, training, postgraduate education, and hospital experience.

In other words the XA physician is quite capable of performing the average operation apt to present itself in Workmen's Compensation practice, and the fee for such operation should in no wise be less than that given to the fully qualified specialist, especially as the fee schedule is a minimum one. Furthermore, in various parts of the state physicians, though fully qualified and often in charge of hospital services, may not confine themselves exclusively to the specialty. Where such physicians are recognized in the community as fully qualified and are the recipients of referred work in private practice they should be regarded as the equal of the full specialist with the "S" rating, and the fees paid for their services should be in no wise less than those paid to specialists. This is the only way that high quality of medical care can be assured the injured workmen. In the larger communities and especially in New York City there are fewer men in this category; more men confine themselves exclusively to the specialties. Hence, the rule was made purely on practical grounds that consultative work where sufficient fully qualified specialists are available should be as far as possible confined to physicians with the "S" rating; but here, too, it would seem only fair that physicians who have passed the test of our boards and been deemed qualified in the surgical and other specialties be permitted to accept certain operative referred work under certain conditions; that is, with the approval of the compensation boards which have qualified them. A hernia operation is indeed within the scope of practice of, e.g., an XA man and, if he is deemed to be qualified to operate on his own patient, he should be qualified to operate on a referred case. His opinion or testimony on a difficult controverted medical matter may not be the equal of that of the more experienced fully graded specialist, and this should be taken into consideration by the referees and the Industrial Board. Aside from the question of expert testimony the complexities of the X and S rating should offer no great difficulty in view of the fact that every physician agrees when he becomes authorized to limit his professional activities to such medical care as his experience and medical training qualify him to render. Furthermore, there are provisions in the law which enable an employer or carrier to transfer a patient from a physician who is deemed unqualified to treat a particular case. The medical societies when appealed to will not hesitate to give an opinion concerning a physician's qualifications for a particular procedure.

Workmen's Compensation Code Letters.—About one year ago the symbol "M-17; all others" was dropped as it did not represent an entity and was superfluous. Your committee now has under consideration the establishment of an additional subspecialty—thoracic surgery (M-17)—and is drawing up a schedule of standards

for the qualification of physicians in this field which will shortly be submitted to the county societies' Workmen's Compensation Boards for their guidance.

Arbitrations.—According to the provisions of Section 13-g, of the Workmen's Compensation Law, an employer or insurance carrier is entitled to arbitration if he objects to a physician's bill within thirty days of its submission. The Law provides that an agreement may be reached between the parties as to the value of medical aid and in the event that no such agreement can be reached after a bill has been submitted, the value of the medical aid rendered shall be decided by an arbitration committee as provided in this section. It was not intended, in our opinion, that the opportunity provided to agree upon the value of medical services should be used as a means of coercion or intimidation, or evasion of the law. The Workmen's Compensation Law provides that a physician may not, in any instance, charge less than the minimum fees in the schedule. And an agreement to accept less than the minimum fees would be tantamount to a violation of the Law and grounds for removal of the offending physician from the panel. The objection to a medical bill, however, may be on the grounds of excessive or too frequent treatments or to treatments for a condition not related to the accident in which event especially in protracted cases an amicable and ethical settlement is possible. In short cases, or even in protracted cases, the routine attempts at deductions from bills except on valid grounds should under no circumstances be countenanced by physicians, and arbitration should be demanded. Any attempts at coercion or intimidation should be reported at once to this Bureau. I believe we have the support of the insurance companies organization in bringing to light any effort to abuse the privilege of settlement or arbitration and to correct the condition. It is largely within the province of practicing physicians to put a stop to any evils or abuses that may exist. Generally speaking, physicians are mindful of the necessity of keeping their bills within reasonable bounds, for the cost of medical care ultimately is borne by the public and the consumer. Physicians should facilitate the payment of their bills by employers or insurance carriers by prompt and complete reporting of cases, as required by law; by cooperation with the insurance carriers medical examiners in the course of treatment and by frequent progress reports, especially in protracted cases; and by observance of the provisions of Section 13-a (5) in regard to the necessity for authorization especially for continued physical therapy. Frequent bulletins on this subject have been issued, and physicians should by this time be fully familiar with procedure. On the other hand, a great responsibility rests upon the employer and insurance carrier, which he does not always fully carry out, to avail himself of the provisions of the Law concerning the examination of claimants under medical care and in providing the attending physician with reports of medical examinations. Physicians should be vigilant in demanding such reports, especially where the carrier makes a request for the cessation of treatment.

Arbitration Statistics.—During the calendar year 1941, a total of \$84,048.78 in medical bills

responsibility in order to assure the injured workman proper medical care by restricting the practice of any physician under the Law to his actual qualifications as determined by the physicians on the compensation boards. The exigencies of the situation which brought about the amendment to the Law in 1935 required a limitation on the scope of a physician's practice so as to improve the quality of medical care rendered to injured and sick workmen and restore them to their work promptly and with as little disability as possible.

Qualifications.—It has been the aim of your Committee and the Director of the Bureau to carry out our functions in respect to the qualification of physicians in such a manner that the intent of the Law be accomplished and that the rating of physicians, either in general practice or in the specialties, would truly indicate their professional qualifications. Compensation committees and boards have now had over six years' experience. After an initial period of uncertainty when certain committees throughout the state gave a multiplicity of symbols to general practitioners, there has been a gradual revision and simplification of code letters. This has not been completed in all counties despite numerous communications from this office explaining the rationale of physicians and the need of simplification of procedure. We strongly urge that the recommendations of this Bureau concerning the code letters for general practitioners be carried out and that special qualifications to general practitioners be granted only where in the opinion of the board such practitioners are recognized by reason of training, postgraduate education, and hospital or dispensary experience as possessing special qualifications in a given field.

It goes without saying that such special qualifications can be given in only one special field and under unusual circumstances in perhaps two or three closely related fields. The coding of *specialists* should proceed using as a guide the standards of qualifications recommended by this committee with such modifications as may be indicated in any given county in accordance with the nature of the local practice. It is further recommended that in the larger cities advisory boards of specialists be set up to serve as advisory to the compensation committees in passing on the qualifications of applicants for the specialist's rating. Where there are insufficient specialists available to constitute a board, it has been recommended that the compensation board itself consist of specialists in the various fields in addition to general practitioners or that such specialists be available in an advisory capacity to the compensation committee or board in evaluating the credentials of applicants for specialist's rating. Where general practitioners apply for special qualification in addition to the general practice rating, these applicants should also be reviewed by the special advisory boards.

It is recommended that the compensation committees proceed with caution in granting limited or full specialist's rating. It should be borne in mind that once a specialist's rating is given the holder thereof is not only entitled to act as consultant, but his testimony before the Department of Labor carries great weight. Also it should be borne in mind that the holder of such a rating pits his opinion against that of the most

highly qualified men in the profession. Wherever there is a doubt as to a physician's credentials, especially in the case of physicians trained out of the state, every effort should be made to verify the credentials; and for physicians educated and trained outside of the United States, especially in the warring countries, it may be impossible to verify the applicant's credentials. It is not unfair to evaluate such applicants' qualifications on the basis of their actual practice in hospital and dispensary positions in their own community. Where a board of committee is in doubt it may require the applicant for a special rating to perform one or more major procedures under the scrutiny of a committee appointed by the board for this purpose. It is also reasonable to ask of any physician that following his internship and residency he have a number of years of experience in actual practice before granting him a full specialist's rating.

Attention is drawn to the x-ray examinations conducted by the State Medical Society at the request of county societies for physicians desiring a rating in radiology or radiation therapy. During the past year seven examinations were held in the metropolitan area for counties in that area; 11 physicians passed and 14 physicians failed. Unless a physician has had adequate training in this specialty and possesses such qualifications as would entitle him to obtain the diploma of the American Board of Radiology or possesses its diploma, he should be examined especially if he is not on the staff of an accredited hospital as roentgenologist. Special ratings in radiology should not be given to any physician or a specialist without full evidence of qualification in the entire field. The mere possession of x-ray apparatus does not qualify a physician to render an opinion on a radiological film. Furthermore, specialists in other fields do not require special x-ray ratings as they are entitled to make x-ray examinations in their own field. A special rating in radiology should not be given unless the applicant is fully qualified in the general field of radiology, with special reference to traumatic lesions of the various parts of the body.

Limited Specialty Qualifications.—In our report of last year we wrote at length on the question of the qualification of physicians with special reference to physicians with limited specialty qualifications. Inasmuch as the Fee Schedule carries fees for general practitioners and specialists under the heading of *consultations and consultant care* the belief has grown up that such specialist's fees should be paid only to physicians having full specialist's rating. However, there is provided in the Fee Schedule no fee other than the general practitioner's fee which can apply where services are rendered by a qualified man who does not have a specialist's rating, for one reason or another.

Under the provisions of Section 13-b-2 the Medical Society is given the power to rate a physician in accordance with his qualifications. It may define the character of medical care which the physician is authorized to render under the Workmen's Compensation Law. It has been the practice in recent years for the Workmen's Compensation Boards to give limited specialty ratings such as XA, XB, XE, etc., for two reasons: Where the physician

nothing of a proper scrutiny of the record of the case. It is the opinion of this Committee that an opinion concerning the necessity for, or advisability of, treatments should in no instance rest upon the mere dictum of a single examiner. It is strongly recommended that there be a change in this procedure. Wherever possible under present conditions no opinion should be given in the absence of full and complete data furnished by the attending physician. He should, furthermore, be notified in advance by the employer or insurance carrier that this issue will be raised at the time of the hearing or examination. Wherever possible the attending physician's presence should be required if he has not in advance agreed that treatment may be stopped or if the claimant himself insists upon further treatment. The ultimate solution of this difficult and vexing problem will depend upon the creation of boards of experts employed by the Department of Labor on a full- or part-time basis, preferably the latter. They should be advisory to the referees and the Industrial Board on questions of treatment and concerning other problems related to the adjudication of the claim from a medical standpoint. These recommendations were originally made by the Medical Society of the State of New York to the commission appointed by Governor Lehman in 1932 to study and report on the medical administration of the Workmen's Compensation Law.

Section 13(d).—Under Section 13(d) the Industrial Board or referee upon the recommendation of the chief medical examiner of the Division of Workmen's Compensation of the Department of Labor, when hearing a claim for compensation, may require examination of any claimant by a physician especially qualified with respect to the diagnosis or treatment of the disability for which compensation is claimed and may require a report from such physician on the diagnosis, the causal relationship between the alleged injury and treatment, and the such claimant.

These so-called "impartial specialists" are designated by the Commissioner from a panel of especially qualified physician compensation boards of the . . . cal societies. These lists may be added to from time to time if the Commissioner requires additional names. The employer or his insurance carrier pays for such examination in an amount set by the Industrial Commissioner.

It was hoped when this addition to the Workmen's Compensation Law was made in 1935 that impartial experts would frequently be called upon by the Department of Labor to decide difficult medical problems confronting the referees and the Industrial Board. Experience proved, however, that in spite of the large number of controverted cases before the Department such impartial examinations have been held relatively infrequently. Rarely have more than 300 such examinations been held in the entire state in any one year in all specialties.

When the revision of the Law was studied in 1932, it was the opinion of the State Medical Society Committee that boards of experts should be set up by the Department of Labor in the various specialties, either on a full-time or part-time basis, to consider medical controversies and act as advisory to the referees on the prob-

lems presented involving causal relationship, degree of disability, necessity for medical treatment, and other medical questions involving industrial accidents and diseases. Instead of boards of experts, the above panel of "impartial experts" was provided for in the Law, and in our opinion this procedure has not added materially to the effectiveness with which claims are settled by the Department of Labor. Furthermore, in recent years the ordinary medical examiners of the Department of Labor have been asked on numerous occasions to decide the question of the necessity for further treatment of a claimant, a task for which they are not generally fitted either by training or experience. Furthermore, owing to the limitations of time and space, they are not able adequately to review the history of the case and make an adequate survey of the problem presented and render an opinion that can do justice to all parties in interest.

Your Director was asked to serve as a member of a subcommittee on Workmen's Compensation of The New York Academy of Medicine which considered for seven months the operation of the Workmen's Compensation system with particular reference to the adjudication of claims for disability. It was the opinion of this subcommittee that the Academy call to the attention of the Department of Labor the desirability of appointing boards of experts in various specialties to pass upon the controversial medical problems. The committee found that under the present system the referees of the Department of Labor are guided in their decisions by the medical opinions of the physicians employed on a full-time basis in the Department. Difficult medical problems may also be decided by the so-called impartial specialists if their services are requested by a referee or the chief medical examiner of the Department. It was the opinion of the Committee that such expert advice could better be given by groups of impartial experts, one group for each specialty, and that if such groups existed more cases would be referred to them than at present are referred to the impartial specialists. The establishment of these special boards would enable thoroughly qualified specialists to become better trained in the handling of compensation cases and become more familiar with the questions at issue under the Workmen's Compensation Law. The referees would have some final authoritative source of medical opinion to which to turn and, although the referee would have the final word, the difficult medical problems would be settled more frequently by medical authority and less often by lay judgment. Once these boards had established a reputation for competence and impartiality, they would tend to minimize controversies and thus effect a saving in time and money to all parties concerned. The existence of these boards would also tend to raise the level of medical testimony before the referees, since such testimony would be evaluated by well-qualified experts.

It has been stated that the Industrial Commissioner has for the past three years attempted to get a provision in the budget to provide for boards in neurology and orthopaedics, but so far this has been unsuccessful. Although it would seem that under the provisions of 13(d) there is ample authority to set up these boards

was arbitrated in the metropolitan area for the counties of New York, Kings, Bronx, Queens, Suffolk, Westchester, and Nassau, in which the amount in dispute was \$78,390.43. Eighty-seven arbitration sessions were held and 773 bills were arbitrated. Awards were made in all but 50 cases, and in most of these prior bills had been paid. Three hundred and twelve bills were settled after the bills were scheduled for arbitration. The awards made for the six larger counties varied between 62 and 53 per cent of the amount in dispute. This included bills in which the full amount was awarded and those in which no award was made. For the upstate region twelve arbitration calendars were held. The total amount of the bills was \$10,993.50 of which \$7,599.50 was in dispute. The amount awarded was 54 per cent of the amount in dispute. Seventy-five bills in all were arbitrated. No awards were made in twelve of these. In 49 cases bills scheduled for arbitration were settled without a hearing. The percentage of awards against the amount in dispute varied from 42 to 94 per cent. With the exception of one calendar in the upstate area the percentage of awards closely followed those made in the metropolitan area. Twenty-nine counties in all were involved.

Attempts have been made continuously to improve the arbitration procedure and to narrow down the issue to the actual evaluation of medical services in each particular instance. A great deal depends upon the physicians selected as arbitrators in the proper and orderly carrying out of this procedure. Such physicians should be strictly neutral and not swayed by personal interests either in the physician whose bills are being arbitrated or in the employer or carrier defending the action. Each bill is an entity and should be decided strictly on its merits. While the rules of legal evidence are not strictly followed, irrelevant issues should be avoided. The arbitration procedure should not degenerate into a trial of the physician for violation of the provisions of the Workmen's Compensation Law which require the attention or action of the compensation committee of the county society. Physicians selected as arbitrators should be thoroughly familiar with the Law as well as the rules and regulations of the Department of Labor governing compensation practice. They should also be familiar with the Fee Schedule and be aware of the fact that it is a minimal one to which the practitioner need not be confined in the event that a fee higher than the minimum is justified. Although, as was stated above, the rules of evidence are not strictly adhered to, unconfirmed statements concerning action taken by the Department of Labor or by the medical examiners of this Department should not be accepted. If there is any question about the compensability of the case or the liability of the employer or insurance carrier the case should be withdrawn from arbitration until the issue is settled by the Department of Labor. Arbitrators should, under no circumstances, permit the introduction of irrelevant evidence and should attempt to carry out the spirit, as well as the letter, of the Law to the end that justice and equity may be served. It is becoming increasingly apparent that the grounds for objection to a medical bill should be more specifically stated by the insurance carrier or employer in the ob-

jection form; and so far as possible the arbitrators should not generally permit, or themselves raise, issues not raised by the objector, bearing in mind that the purpose of arbitration is to arrive at an equitable decision concerning the value of the services rendered by the attending physician in accordance with the nature of the injury sustained or the illness under treatment, and the medical services rendered. A physician as an arbitrator must under no circumstances become an advocate.

It is our opinion that there should be present at each arbitration proceeding, either as arbitrator or observer, a representative of the Compensation Committee or Board who is thoroughly familiar with all phases of arbitration and of the rules and regulations of the Department of Labor, as well as of the Workmen's Compensation Law.

Administrative Procedures—Department of Labor.—An important change in procedure has been adopted by the Department of Labor in respect to reports issued by the medical examiners of the Department. Heretofore, a typewritten copy of the medical report was given to the claimant, or to his representative and, even though it contained important information to the attending physician, it frequently was not brought to his attention. For a number of years we have been attempting to correct this and recommend that a copy of all such reports be mailed to the attending physician. Owing to the lack of personnel in the Department this was not deemed feasible but in December, 1941, we were notified by the Deputy Industrial Commissioner, Mr. Michael Murphy, who has had this matter under consideration, that in the future the Department will print prominently on all such reports the words, "To The CLAIMANT: Show This Report to Your Doctor." Physicians should be on the alert and request such reports from claimants after hearings and medical examinations at the Department of Labor. These reports should be retained as part of the physician's record. Where the report contains a recommendation concerning medical treatment with which the physician does not agree, he should in writing notify both the employer or insurance carrier and the Department of Labor of his opinion and recommend that the patient demand another hearing, to which the attending physician may be subpoenaed to appear by the claimant or, if he cannot appear, provide the claimant with the necessary factual data on which his opinion as to medical treatment is based.

This brings up the question as to the authority or advisability of medical examiners of the Department of Labor expressing an opinion as to the advisability of treatment being stopped or continued or the nature of the treatment to be rendered. A decision is often difficult and may require an opinion from a mature physician or specialist. It is questionable whether every examiner of the Department of Labor is qualified to express an opinion as the result of his examination or based upon his qualifications. Furthermore, the increased number of cases resulting from the enlargement of industrial establishments and increased industrial activity precludes, in most instances, the possibility of a complete and adequate examination of the patient, to say

April 1, 1942]

would ascertain at the time of the closing of the case whether a bill for medical care was outstanding or payable, thereby enabling the carrier at the time to make such objection or controversy as is permitted under the provisions of the law.

Legislative.—Again this year, bills have been introduced in the Legislature to permit the admission of nonemergent cases requiring hospital treatment to municipal hospitals. Occasionally, voluntary and proprietary hospitals refuse admission unless authorization for hospital expense is given in advance of admission. This usually involves cases under prolonged treatment and in which the case has been closed and liability may have terminated. In any event there may be a controversy over the liability of the employer or carrier. Although the physician is willing to take a chance on his fee, the hospital often refuses admission unless the hospital bill is authorized. Many hospitals are willing to admit such claimants to their wards but not to their private pavilions; in which event the free choice principle may become nonoperative if the patient's physician is not connected with regular staff of such hospital.

There is at present in the metropolitan area a committee of hospital directors which is attempting to solve this problem and obtain hospitalization for such cases as may be denied admission. In practically every instance your Director has succeeded in obtaining admission when appealed to either by the Labor Department or by the physician in charge. Therefore, it does not seem necessary to make any change in the Law at this time. Such a change would involve opening up municipal hospitals to non-emergent cases where the employer refuses authorization. In many such cases compensability is ultimately established. The injured workman is entitled to semiprivate care and should not become a free ward patient. Furthermore, the passage of such a bill would in a large measure nullify the free choice principle.

C-2 Forms.—Every accident must be reported promptly by the employer on a C-2 form. Employers often are negligent or tardy in reporting, and in certain sections of the state physicians have filled out C-2 reports and submitted them to the employer for signature and filing. The Labor Department has rendered an opinion in which it holds that this practice is improper and physicians have been so instructed. The physician is required to fill out only C-104, C-4, C-5, C-14, and C-27 reports, as indicated. The employer must fulfill his own responsibilities.

Duties and Responsibilities of Local County Medical Society Workmen's Compensation Boards or Committees.—In the larger counties where full- or part-time executives are appointed and where the Workmen's Compensation Committees have adequate secretarial help, they serve as intermediaries between practicing physicians and employers or insurance carriers in the adjudication of disputes or misunderstandings over medical bills and other matters concerning the administration of the Workmen's Compensation Law. It is recommended that this procedure be adopted wherever possible by all of the county society compensation boards. Employers and insurance carriers should be encouraged

to bring their problems and difficulties to the Society, thus establishing better relationships between the doctor and the employer or carrier. Many disputes over the treatment of patients and the rendering of bills could be thus eliminated. Just as the physician should be encouraged to seek the advice and guidance of his county medical society workmen's compensation board so the insurance carrier and employer should likewise be encouraged to work in closer relationship with the county society compensation boards. The office of the Director of Workmen's Compensation is at all times available in this work.

Insurance Carriers Claim Departments.

The commissions appointed by various governors of this state to study the administration of the Workmen's Compensation Law have in every instance recommended that there be a separation of the medical and claims departments of insurance carriers. In actual practice this has not been achieved and in the opinion of your Director is mainly responsible for some of the difficulties in administration and evils that still exist in the functioning of the Workmen's Compensation Law. The chief purpose of the Law is to provide adequate medical care to the injured workman, to compensate him for time lost, to rehabilitate him, and to get him back to work as quickly as possible. The cost of medical care should be as reasonable as compatible with high quality medical service. Theoretically, all insurance carriers agree on this principle, but in actual practice there often appears to be a tendency to consider "expenses" of prime importance and the patient and his welfare of minor importance. It is imperative that employers and insurance carriers have expert medical advice available at all times in order to protect their interests. Under the law they are given certain responsibilities and privileges, and most of these when related to medical care should be exercised by properly qualified physicians. Unfortunately, most of the contacts between physicians and insurance carriers are with laymen and not with physicians. The layman often has a smattering of medical knowledge and sets himself up as a judge of both the quality and quantity of medical care necessary. Physicians are frequently annoyed, to put it mildly, by the attempts of laymen to intrude themselves into the medical problem presented. This meddling involves not only the question of medical expense but too often the actual medical conduct of the case.

It goes without saying that the interests of both insurance carrier and doctor would be greatly advanced if thoroughly qualified and respected physicians were employed by insurance carriers to make contact with the medical profession. Physicians are ready to cooperate fully with employers and insurance carriers and this contact should be established as soon as an injury is reported. The frequent practice of some insurance carriers representatives objecting to medical bills or continuation of treatment without even having had a medical examination of the claimant during the early stages of the patient's illness cannot be too strongly condemned. It is hoped that steps will be taken by carriers to assure the separation of the medical and claims division of all insurance carriers.

from lists of physicians deemed duly qualified by the medical societies, so far the Commissioner has not been able to bring about their appointment. Inasmuch as the costs of this service would have to be borne by the insurance carriers, there undoubtedly would be some opposition or delay. For this reason it would seem better to recommend that the law be amended to provide for the setting up of full-time or part-time boards in the various specialties, but especially in orthopaedic surgery and neurology to begin with, and that provisions be made for salaries or emoluments. The opinion of these boards should be final as to medical facts and advisory to the Industrial Board and the referees. These boards should be appointed by the Industrial Commissioner on the recommendation of the Medical Society of the State of New York, or by its subsidiary compensation boards.

Department of Labor Procedure.—This brings us to the question of the adequacy of procedure and personnel in the Department of Labor. There frequently arise situations in respect to medical care which can only be resolved by prompt hearing and examination before the Department of Labor. Under present conditions, although we feel that such speeding up of hearings would redound to the advantage of the injured workman and in controverted cases enable him to receive medical care which, because of the nature of the controversy, must often be postponed, the lack of adequate personnel in the Department of Labor now renders this impossible. We have been informed by the Director of the Division of Workmen's Compensation that the volume of cases, open and pending, before the Department in New York City alone increased from 46,447 at the end of 1940 to 54,567 on December 31, 1941. This increase of a little over 8,000 during the year is equivalent to the work normally accomplished by two full-time referees. A further illustration is the fact that during the year 1940 approximately 1,348,000 papers were received, and during the last year this had increased to approximately 1,542,000. These papers of which there are no cases indexed are filed in the so-called "no-claim file." The amount of correspondence, reports of accidents, etc., in these files has grown tremendously. When a case folder is assembled, it is necessary to search this no-claim file in order to be certain that all papers previously received by the Department are included in the case folder. As the no-claim file has expanded in volume, the searching of each individual case requires more time; consequently, it is necessary to divert much of the time of higher salaried examiners to the elementary function of filing and searching these papers, which should be done by other and lower paid individuals. Medical examinations in the New York office have increased from 67,959 for the year 1940 to 71,406 for the year 1941, an increase of nearly 3,500 medical examinations. I believe these figures indicate the critical need for an increased personnel in the Department of Labor if the interests of the injured workmen are to be properly conserved, to say nothing of the advantage that would accrue to the medical profession through more prompt examinations. We strongly recommend, despite the need for economy in government, that the personnel of the

Department of Labor be increased. Increased efficiency through more prompt handling of claims would unquestionably, in our opinion, more than offset the cost to the insurance organizations and employers concerned in the way of more prompt hearings and prompt payment of claims and closing of cases.

Industrial Board.—Under date of March 3, 1941, a communication was issued by the Director of Workmen's Compensation to assistant commissioners and referees advising them that on February 14, 1941, the Board adopted a resolution to the effect that the referees be instructed in cases in which disability is less than seven days they should make the following findings: "No compensation due—disability less than 7 days—case closed." The reason for the adoption of this resolution was the fact that the Industrial Board had noticed that in a number of cases the referees used the phrase, "disallowed—disability less than seven days." The referees have closed these cases or disallowed them on the ground that no wages were lost. In the opinion of the Industrial Board this was not a proper action because under the provisions of Section 25 an award must be made to reimburse the employer if such reimbursement is requested either by the employer or the claimant. It was brought to the attention of Mr. Boyer by your Director that under a recent decision of the Court of Appeals of this state it was the opinion of the Court that compensation should not be restricted or confined in its definition to money compensation alone. The provision of medical care, in the opinion of the Court, was a form of compensation equally, if not more, important to the claimant than compensation for time lost. The Industrial Board has frequently taken advantage of a situation in which an employer or insurance carrier has paid for medical attention in deciding the question of accident, etc. In other respects medical care has not necessarily been looked upon as conterminous with compensation. Though it is true that compensation for medical care is not paid by the claimant but, under the provisions of Section 13, by the employer or insurance carrier, it should be looked upon and, in the opinion of the Court, should be regarded as compensation. Although a claimant may not be entitled to money compensation for time lost because such time lost is not equivalent to the waiting period, he may be entitled to medical care during this period of disability, and a medical compensation bill is incurred which under the provisions of the law is payable by the carrier or employer. It is therefore our opinion, and we recommend, that the referee should be instructed, when making a determination of compensation due, to indicate that medical or hospital expense has been incurred or payable so that there may be no question in the mind of an employer or insurance carrier as to the reason why the case was closed. This is emphasized because in a number of instances insurance carriers have utilized the fact that the Department of Labor has not passed upon the question of medical care, when closing a case, as a basis for refusal to pay for medical care often requiring a reopening of the case at a time when the patient may be no longer available or disinclined to appear after he has resumed his work. If the procedure recommended were adopted, the referee

rests on his contention that he did not authorize such special services or that the circumstances did not require them. Under the present law the Industrial Board has taken the position, and properly so, that it has no power to pass upon such claims or to make awards to physicians in hospitals for such services.

The Industrial Board bases its limitation of power to affix the cost of medical care on the provisions of Section 24 of the Workmen's Compensation Law which reads as follows:

"Cost and Fees. If the court before which any proceedings for compensation or concerning an award of compensation have been brought, under this chapter, determines that such proceedings have not been so brought upon reasonable grounds, it shall assess the cost of the proceedings upon the party who has so brought them. Claims of attorneys and counselors at-law for legal services in connection with any claims arising under this chapter, and claims for services or treatment rendered or supplies furnished pursuant to subdivision (b) of Section 13 of this chapter, shall not be enforceable unless approved by the board. If so approved, such claim or claims shall become a lien upon the compensation awarded, but shall be paid therefrom only in the manner fixed by the board. . . ."

Section 13(b) referred to involves only out-of-state cases.

As properly stated by the Bar Association Committee, proper and willing medical treatment of injured employees is not encouraged if physicians and hospitals are forced to litigation in order to collect their bills. The spirit of the law would be defeated by such litigation. The purpose of the statute would be defeated if liability for medical services or hospital care imposed by law cannot easily be enforced. An amendment is therefore required to eliminate all doubt about the authority and jurisdiction of the Industrial Board over claims for medical services. At the present time the Industrial Board has jurisdiction only where the injury occurred outside of the state [Section 13(b) (2)], or where the employer has failed to provide compensation for his employees (Section 13-g subdivision 4 amended in 1940). According to the Bar Association there seems to be no logical or historical reason for the distinction created by these two exceptions. They should embody the general rule, which was probably the legislative intent when the Law was amended in 1935. It must be remembered that under Section 13-f the physician rendering treatment to a compensation claimant may not accept or collect a fee from the claimant but must have recourse for payment to the employer under the provisions of the Law. In the decision of the Supreme Court in the Szold case the Court held that recourse to the employer for payment of medical bills shall be had only under the statute. Despite this the Industrial Board has always claimed that it has no jurisdiction under the provisions of the Law, as amended in 1935, to fix the cost of medical care except in out-of-state cases and in accordance with the 1940 amendment where the employer failed to carry insurance. It has been held that a physician is not a party in interest under the statute by reason of his claim for medical services, that medical expenses are not compensation, and

that the Industrial Board has no authority to make an award to other than an injured employee, therefore, making it necessary for the physician to sue at law in order to collect his bill. In order to insure beyond doubt realization of the essential object of those parts of the Workmen's Compensation Law discussed above, it is necessary to amend the Law. Legislative authority to do so is clear.

Therefore, the following amendment to Section 13-a(5) and Section 13-g(4) is recommended:

"Section 13-a(5). No claim for specialist consultations, surgical operations, or physiotherapeutic procedures costing more than \$25 shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency. No claim for x-ray examinations or special diagnostic laboratory tests costing more than \$10 shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency. Where payment of a claim for such special services is refused on the ground that such special services were not authorized as herein provided, the physician or hospital presenting such claim shall have the right to appeal to an arbitration committee as provided in subdivision two of Section 13-g to determine whether such special services were authorized by the employer or by the commissioner, and if not, whether such authorization was unreasonably withheld or whether such special services were required in an emergency. The amount of any such claim, if disputed, shall also be determined at the request of the physician or hospital presenting such claim, or at the request of the employer or insurance carrier by arbitration in the manner provided in subdivision two of Section 13-g and an award to the physician or hospital in accordance with the decision of the arbitration committee may be able and enforced as provided in said subdivision two of Section 13-g."

Subdivision (4) of Section 13-g is also amended to read as follows:

"(4). The Industrial Board may make an award to the physician or hospital entitled thereto upon a claim presented by such physician or hospital to the employer or to the commissioner for the value of medical services or treatment rendered to an employee, in accordance with the schedules of fees and charges prepared and established under the provisions of Section 13-a of this chapter, irrespective of whether the employer has secured compensation to his employees as required by Section 50 of this chapter or has failed to do so, and a default in the payment of such award may be enforced in the manner provided for the enforcement of compensation awards as set forth in Section 26 of this chapter."

The industrial board shall have full power and authority to determine all questions in relation to the payment of such claims pre-

It is the Board's conviction that greater responsibility should be given to their medical departments, and the physicians employed therein, in regard to medical matters. A closer cooperation between the medical departments of insurance carriers and employers and attending physicians, especially during the acute phases of treatment, would in a large measure do away with many of the disputes which ultimately bring about objections to a physician's bill. In this connection it might also be said that such separation of medical and claims departments, and the providing of properly trained medical examiners by carriers would unquestionably redound to the advantage of the injured workmen and lead to the avoidance of delays in the institution of medical care, especially operative treatment. It is pleasant to report the impression that there has been some improvement in this respect during the past few years, but there is still room for improvement.

Fee for Testimony.—The following resolution was adopted by the Industrial Board of the Department of Labor on June 7, 1940, and promulgated to the medical profession in the fall:

"Resolved, That under the Fee Schedule for attendance of physicians at hearings, adopted by the Industrial Board at its meeting on June 7, 1940, the Board believes that if a physician's appearance for the purpose of testifying at a hearing is required, he shall receive the \$25 or \$10 fee, according to his designation, as provided in the schedule. If at the same session, he is required to testify in another case, whether before the same referee or not, he shall be entitled to receive an additional \$12.50 or \$5.00 fee, according to his designation. If the same physician is required to attend a hearing for the purpose of testifying on the same day, but at the afternoon session, he shall be entitled to receive the larger fee, even though he had appeared at a hearing in the morning session, and an additional \$12.50 or \$5.00 fee, according to his designation, for any additional case in which he may be required to testify at the same session, even though such case may come before the same referee."

This means that if a physician with a specialist's rating testifies in 2 cases in the morning, he will be paid \$25 for the first and \$12.50 for the second at the same session. If he is required to stay over until the afternoon, he will again receive the full fee of \$25 for the first case and \$12.50 for any subsequent cases. The fee for the general practitioner under these circumstances will be \$10 and \$5.00, respectively. Under certain conditions the referees may award a mileage fee if the physician must travel a considerable distance to the hearing place. Where the physician is subpoenaed by the insurance carrier and serves as their witness he should make arrangements with the carrier for a fee for his testimony.

The above applies only to cases injured on and after July 1, 1935.

Amendments.—We have been fortunate in having the support of the Bar Association of the City of New York, through its Committee on Law Reform, in formulating and having introduced into the Legislature a number of bills to

improve the functioning of the Workmen's Compensation Law, especially as it concerns section 13. Section 13-g(1)(2) should be amended so as to give the Industrial Board the power to make awards to physicians in hospitals for medical care and services where the value of such services has been fixed or determined (1) by the submission of a bill which was not objected to within thirty days in compensable cases and (2) where the value of the bill has been determined under the provisions of Section 13-g(1) by arbitration. As the Law now stands, without amendment, unless the employer or carrier pays, the physician or hospital must sue at law at considerable expense and trouble, especially where the bill is small. As was pointed out by Justice Loughran of the Court of Appeals, to force doctors and hospitals to settle and collect their bills "by the varying and uneven result of ordinary litigation would perhaps in the long run impair the grade of medical care secured to those on whose lives and safety the common welfare depends."

In the same decision the Court also said: "The medical care which the employer must furnish is part of the statutory compensation of the workman." The Committee of the Bar declared that the enforcement of such liability for medical care is as properly the function of the Industrial Board as is the enforcement of the employer's liability for monetary compensation.

At the suggestion of your Committee, the Bar Association took up a further amendment to Section 13-a, subdivision 5, which at present reads:

"Section 13-a(5). No claim for specialist consultations, surgical operations, or physiotherapeutic procedures costing more than \$25 shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency. No claim for x-ray examinations or special diagnostic laboratory tests costing more than \$10 shall be valid and enforceable, as against such employer, unless such special services shall have been authorized by the employer or by the commissioner, or unless such authorization shall have been unreasonably withheld, or unless such special services are required in an emergency."

The statute as above quoted does not provide for the manner in which questions of fact arising under this section, such as the existence of an emergency or other conditions requiring special medical services, are to be determined or by what tribunal. Therefore, arbitration as under Section 13-g(1) should be provided. Such arbitration is provided where a physician accuses an employer or his agent of improper transfer, Section 13-a(3), and there is no reason why arbitration should not be provided for ascertaining the facts under Section 13-a(5). At the present time physicians or hospitals with claims for special medical services under Section 13-a(5) in excess of \$25 or \$10, respectively, and especially where the employer or carrier claims that physical therapy in excess of \$25 was not authorized, are required to sue at law if the employer

action against such other within the time limited therefor by subdivision one, such failure shall operate as an assignment of the cause of action against such other to the state for the benefit of the state insurance fund, if compensation be payable therefrom, and otherwise to the person, association, corporation, or insurance carrier liable for the payment of such compensation. If such fund, person, association, corporation or carrier, as such an assignee, recover from such other, either by judgment, settlement or otherwise, a sum in excess of the total amount of compensation awarded to such injured employee or his dependents and the expenses for medical treatment paid or for which liability has been incurred by it, together with the reasonable and necessary expenditures incurred in effecting such recovery, it shall forthwith pay to such injured employee or his dependents, as the case may be, two-thirds of such excess, and to the extent of two-thirds of any such excess such recovery shall be deemed for the benefit of such employee or his dependents. When the compensation awarded requires periodical payments the number of which cannot be determined at the time of such award, the Board shall, when the injury or death was caused by the negligence or wrong of another not in the same employ, estimate the probable total amount thereof upon the basis of the survivorship annuitants table of mortality, the remarriage tables of the Dutch Royal Insurance Institution and such facts as it may deem pertinent, and such estimate shall be deemed the amount of the compensation awarded in such cases, for the purpose of computing the amount of such excess recovery, subject to the modification thereof as herein-after provided."

The Bar Association has independently of the above amendments suggested an amendment to Section 13-g, to give to the Industrial Board the power to make an award to a physician or hospital in the event that the employer or carrier has not objected to a doctor's bill within thirty days, thus making the bill due and payable and deeming it to be the fair value of the services rendered. An amendment to Section 13-g(2) also gives to the Industrial Board the power to make an award in accordance with the decision of the arbitration committee in the event that an employer or carrier refused to honor such decision. Whether this second amendment is necessary is doubtful since arbitration awards are deemed to be enforceable under the statute.

The first amendment concerns Section 13-g, subdivisions 1 and 2. The italic sentences are new.

"Section 13-g. Payment of bills for medical care.

(1) Unless within thirty days after a bill has been rendered to the employer by the physician or hospital which has treated an injured employee, such employer shall have notified the commissioner and such physician or hospital in writing that such employer demands an impartial examination of the fairness of the amount claimed by such physician or hospital for his or its services, the right to such an impartial examination shall be deemed to be waived and the amount claimed by such

physician or hospital shall be deemed to be the fair value of the services rendered by him or it, and the Board may make an award to such physician or hospital in the amount claimed by such physician or hospital. A default in the payment of such award may be enforced in the manner provided for the enforcement of compensation awards as set forth in Section 26 of this chapter.

(2) If the parties fail to agree as to the value of medical aid rendered under this chapter such value shall be decided by an arbitration committee consisting of two physicians designated by the president of the medical society of the county in which the claimant resides, and two physicians, also members of the Medical Society of the State of New York, appointed by the employer or carrier. The majority decision of the arbitration committee shall be conclusive upon the parties as to the value of the services rendered. In the event of equal division, the committee shall select a fifth physician, also a member of the Medical Society of the State of New York, whose decision shall be conclusive. If the physician whose charges are being arbitrated is a member in good standing of the New York Osteopathic Society or the New York Homeopathic Society, the members of such arbitration committee to be appointed, similarly, shall be physicians of such organization and the president of such organization shall make the designation provided herein. *The Board may make an award to the physician or hospital for his or its services in accordance with the decision of the arbitration committee as evidenced by a copy of said decision certified by at least three of the members of the arbitration committee and a default in the payment of such award may be enforced in the manner provided for the enforcement of compensation awards as set forth in Section 26 of this chapter.*"

Industrial Health.—Industrial health is assuming greater importance particularly in view of the national defense program. Our Committee on Public Health and Education has created a special study committee to interest itself in industrial health problems. Dr. H. H. Bauckus is chairman, member of this committee is Ver Mitchell, chairman of the Public Health and Education Committee, took part in the Program of the Congress on Industrial Health of the American Medical Association which was held in Chicago on January 13 to 14, 1942.

This committee has under consideration the providing of educational programs in industrial medicine and surgery. It is hoped to attract the attention of the medical profession as a whole to those aspects of industrial practice for which medical leadership and initiative are required. Physicians must be trained to render satisfactory service in industry, and opportunities must be afforded for such instruction for medical and postgraduate students. Conservation of man power is of great importance especially in wartime, and in this program well-trained physicians must play a leading part. Small industry must be served as well as large organizations, the latter being usually well staffed with competent medical advisers, while the smaller often lack the same. There are

sented to it and with respect to the employer's liability for medical treatment and care of his employees.

In any case where the amount claimed has been fixed or determined under subdivision (1) or (2) of this section the award shall be in such amount. In any case where the amount of the claim when presented has not been so fixed or determined and is in dispute the Board shall, at the request of any party, or on its own motion, refer the question of the fairness of the amount claimed to an arbitration committee such as provided in subdivision (2) of this section and the award shall be in the amount determined by such committee.

In cases where the employer has failed to secure compensation to his employees as required by Section 50 of this chapter the payment of the claim of the physician or hospital for medical or surgical services or treatment shall be subordinate to that of the payment of the claim for compensation of the claimant or his beneficiaries."

Section 13-C of the Workmen's Compensation Law reads as follows:

"(c). The liability of an employer for medical treatment as herein provided shall not be affected by the fact that his employee was injured through the fault or negligence of a third party, not in the same employ, *unless and until notice of election to sue or the bringing of suit against such third party*. The employer shall, however, have an additional cause of action against such third party to recover any amounts paid by him for such medical treatment, in like manner as provided in Section 29 of this chapter."

Under this section it has been held that compensation and medical expense are payable until notice of election to sue the third party or a suit against such third party is begun. Section 29 of the Workmen's Compensation Law was amended in 1937 to give employees the right to all compensation benefits regardless of the commencement of third party suit, including medical care. Section 29 provides for the continuation of compensation payments. Monetary payment as well as the benefits of medical care must be regarded since the decision in the Szold case as two parts of the compensation provided for the employee by the compensation law.

In a recent decision of the Appellate Division, Third Department, January 7, 1942, the Court held that subdivision (c) of Section 13 releases the employer from liability for medical expenses after a suit against the third party is begun. It was the opinion of the Court that the 1937 amendment of Section 29 was not sufficient to repeal or annul the limiting effects of Section 13-C.

The Court stated: "Doubtless the problem should receive further legislative clarification, but as the statute now exists we do not think that the provisions of Section 29 have superseded or destroyed the limitations contained in Section 13." The employer is protected by a right of subrogation and a cause of action against the third party. While it was the opinion of the Industrial Board that the Legislative amendment to Section 29 in 1937 superseded the limiting Section 13-c, this view has been superseded by the opinion in the case of *Wolkenstein vs. Lumin-*

art Lampshade Products, Inc., cited above. Therefore, it is recommended that that portion of Section 13-c which limits liability for medical expenses to those services rendered before the commencement of the third party suit be eliminated and that Section 29 be amended so as to provide that the employer or carrier shall have a lien or right of action for medical expenses incurred, as well as for those actually paid, where a third party is responsible for the injury. These amendments follow:

"(c). The liability of an employer for medical treatment as herein provided shall not be affected by the fact that his employee was injured through the fault or negligence of a third party, not in the same employ, but the employer shall have a cause of action against such third party to recover any amounts paid by him for such medical treatment or for *which he has incurred liability under the provisions of this chapter* and such other rights as are provided in Section 29 of this chapter."

This also necessitated an amendment to Section 29 as follows:

"Section 1. Subdivisions 1 and 2 of Section 29 of the Workmen's Compensation are hereby amended as follows:

"1. If an employee entitled to compensation under this chapter be injured or killed by the negligence or wrong of another not in the same employ, such injured employee, or in the case of death, his dependents, need not elect whether to take compensation under this chapter or to pursue his remedy against such other but may take such compensation and at any time either prior thereto or within six months after the awarding of compensation, pursue his remedy against such other subject to the provisions of this section. If such injured employee, or in the case of death, his dependents, take or intend to take compensation under this chapter and desire to bring action against such other, such action must be commenced not later than six months after the awarding of compensation and in any event before the expiration of one year from the date such action accrues. In such case, the state insurance fund, if compensation be payable therefrom, and otherwise the person, association, corporation or insurance carrier liable for the payment of such compensation, as the case may be, shall have a lien on the proceeds of any recovery from such other, whether by judgment, settlement or otherwise, after the deduction of the reasonable and necessary expenditures, including attorney's fees, incurred in effecting such recovery, to the extent of the total amount of compensation awarded under or provided or estimated by this chapter for such case and the expense for medical treatment paid or for which liability has been incurred by it and to such extent such recovery shall be deemed for the benefit of such fund, person, association, corporation, or carrier. Notice of the commencement of such action shall be given thirty days thereafter to the commissioner, the employer and the insurance carrier upon a form prescribed by the commissioner.

"2. If such injured employee, or in case of death, his dependents, has taken compensation under this chapter but has failed to commence

should aid in the interpretation of the occupational relationship.

"In the majority of cases of occupational dermatosis, the following criteria will usually be found to apply:

"(a) The dermatologic diagnosis is a dermatosis in which the role of an occupational causal (major or contributory) factor has at some previous time been established beyond reasonable doubt.

"(b) The person has been working in contact with an agent known to have produced similar changes in the skin.

"(c) The time relationship between exposure to the agent and the onset of the dermatosis is correct for that particular agent and that particular abnormality of the skin.

"(d) The site of the onset of the cutaneous disease and the site of maximum involvement are consistent with the site of maximum exposure.

"(e) The lesions present are consistent with those known to have followed the reputed exposure or trauma.

"(f) The person is employed in an occupation in which similar cases have previously occurred.

"(g) Some of the person's fellow workers using the same agent are known by the examiner to have similar manifestations due to the same cause.

"(h) So far as the examiner can ascertain there has been no exposure outside of occupation which can be implicated.

"(i) If the diagnosis is dermatitis, the following items are important:

"(1) Attacks coming after exposure to an agent, followed by improvement and clearing after cessation of exposure, constitute most convincing evidence of the occupational factor as a cause.

"(2) The results of patch tests performed and interpreted by competent dermatologists corroborate the history and examination in the majority of cases.

As previously indicated, these criteria are difficult of application in certain groups of cases: (a) cases in which there is sensitization, (b) cases in which there is accentuation of existing cutaneous disease by occupational factors, (c) cases in which there are supervening complications of other dermatoses and occupational dermatoses, (d) cases in which much time has elapsed between the development of the dermatosis and the examinations, and (e) cases in which there has been overtreatment.

Increasing Medical Costs.—On December 6, 1941, a confidential inquiry was directed to the chairmen of all compensation boards throughout the state requesting detailed information concerning the cost of all items entering into Workmen's Compensation practice such as the cost of technical help, nursing service, secretarial service, medical and surgical supplies, drugs, instruments, office rental, etc., in order to determine whether we would be justified in asking for a change in the Fee Schedule at this time. Replies have so far been received from twenty-three compensation boards. At the time of going to press we have not yet been able completely to analyze the replies. They seem to indicate a need for an upward revision of the schedule

especially for low cost visits and other items. There again seems to be a universal demand for the elimination of the 5 per cent discount allowed for payment of bills over \$15 within thirty days.

Unions.—The free choice principle is one of the most important and valuable assets of the amended Workmen's Compensation Law. This principle has been affirmed by the highest courts of the land, and we should not lightly permit this principle to be violated and thereby deprive an injured workman of his right to select to treat him a physician in whom he has confidence. The injured workman is amply protected as to the competence of the physician by other provisions of the law limiting a physician's practice to what he is actually qualified to render. The majority of workmen of this state are aware that they may select their own physician. From time to time we have had evidence that employers and insurance carriers have by direct or indirect means attempted to intimidate or coerce claimants to accept medical care at the hands of physicians either directly or indirectly in their employ or pay or under their control. Fortunately, this practice has ceased to a large extent. There are still many injured workmen who apply to their employers for medical care and are satisfied with the physicians recommended. They may on occasions change to a physician of their own choice. In some instances employees still refuse to exercise their right to free choice fearing that they may jeopardize their positions. Nevertheless, on the whole the free choice principle is becoming more firmly established year by year. There has been an increasing tendency on the part of labor organizations to employ physicians on a salary or fee basis to render all sorts of medical attention to members of the labor unions. Some unions have even established clinics, consultation service, and hospitalization for their members. The Department of Labor has recognized the principle that a union may assist its members in the handling of compensation cases, and the Industrial Board has licensed certain representatives to assist union members at hearings of the Department. We have no wish to interfere here or to minimize the importance of union representation in compensation claims. We further have no desire to prevent or interfere with the injured workman seeking the attention of a qualified physician employed by a labor union, provided that the member seeks such services of his own free will. The question arises whether once a claimant has selected his family physician, or some other physician of his own choice, to treat him, he should be required to remain under the supervision of a union physician, or transfer his care to such physician, at the request of some union official, or at the direction of the physician of the union. It is not intended to convey the impression that the practice of coercing union members to receive medical attention at the hands of physicians appointed by unions is universal or even general, but there have been a few instances in which complaints have been received indicating that patients were transferred from the physician of their choice to a physician employed by a labor union and one not preferred by the injured workman. We believe that the patient's right of free choice should be limited only by the provisions of the Workmen's Compensation Law relating to quali-

questions involved concerning free choice of physician for certain types of service involved. Knowledge on the part of the physician of industrial medical work in its various aspects is imperative. The profession generally should be aware of the necessity of keeping workers at work throughout the year, and an effort should be made to reduce the number of days of absence due to illness not the result of accident or occupational disease. Accurate statistics on this phase of lost time are not available. While the blame for such loss of time can hardly be placed on the shoulders of the medical profession, some effort should be made to create closer relationships between management and the profession in order to bring under the physician's care, as promptly as possible, those who are reported ill and absent from work.

First-Aid Stations.—Because of the base increase in defense projects throughout the state, many new plants have arisen and old ones have been expanded. It may be estimated that the number of accidents will increase many fold and occupational diseases will likewise increase in number. In regard to the latter, the importance of expert medical advice in regard to industrial hazards, safety measures, etc., cannot be overestimated if man power is to be conserved. First-aid stations are being created throughout the state, and it is imperative that there be adequate control over these establishments. Under the Workmen's Compensation Law a *medical bureau* cannot be set up without the sanction of the Medical Society Compensation Committee and the payment of a license fee to the state. First-aid stations have absolutely no governmental control. They may or may not be properly equipped and staffed, and the provisions of the Workmen's Compensation Law regarding the reporting of cases may not be carried out. Furthermore, there is no provision whereby the medical societies' compensation committees may inspect such first-aid stations and determine whether they are properly equipped and conducted, and in accordance with the provisions of the Workmen's Compensation Law. In some stations continued medical care may be given, and an unlicensed individual may be assuming the responsibilities of a physician. The danger to the injured workmen of improper medical care is obvious. We strongly recommend that provisions be made in the public health and Workmen's Compensation Laws for the inclusion of first-aid stations.

An additional word may be permissible, drawing attention to occupational diseases that arise in the course of, as the result of, or which are peculiar to, the individual activity in which an employee is engaged. While the more common occupational diseases, and particularly the industrial dermatoses, are well known, there are numerous conditions peculiar to modern industry which are not well known and, hence, are apt to be overlooked by physicians. Attempts should be made to familiarize physicians with the various industrial illnesses and the symptomatology, diagnosis, and treatment of same. The amended C-4 form should be helpful and physicians should avail themselves of the services of the Department of Industrial Hygiene (through the help of Dr. Leonard Greenburg, director) in cases where an employee may be suffering from

symptoms suspicious of poisoning to determine whether a hazard exists at the place of employment.

Industrial Dermatitis.—The importance of industrial dermatitis under the Workmen's Compensation Law cannot be overestimated. The report of the Committee on Industrial Dermatitis of the Section on Dermatology and Syphilology of the American Medical Association published in the February 21, 1942, issue of the *Journal of the American Medical Association* should be studied carefully.

This report is in line with a similar study made by a special committee appointed by the Section on Dermatology of the State Medical Society and working as a subcommittee under our Committee on Workmen's Compensation. In our previous reports to the House, we have stressed the importance of closer cooperation between the medical profession and the insurance carriers and employers, so as to bring about a *modus vivendi* among dermatologists, industrial physicians, and employers which would afford to the employee prompt and efficient diagnosis and treatment for cases of occupational dermatitis and at the same time enable a qualified physician to be paid at least a minimum for a diagnosis in a doubtful or noncompensable case. The arrangement suggested would, we believe, be in the interest of all parties concerned and would, by prompt diagnosis and efficient early treatment, save the employers and carriers considerable money in controverted doubtful cases. Our proposal has been under consideration by the insurance carrier's organization for over a year, and it looks as though we are no nearer a solution of this problem than we ever were, despite what we believe to be a favorable attitude toward our proposals on the part of the insurance carriers.

We are herewith reprinting the criteria for the diagnosis of occupational dermatoses published by the Committee of the American Medical Association:

"Criteria for the Diagnosis of Occupational Dermatoses.—The Committee on Occupational Dermatoses submits this statement of the criteria for the diagnosis of occupational dermatosis with the purpose of improving the proper interpretation of manifestations on the skin resulting from occupational causes. In so doing, the committee realizes fully the inadvisability, as well as the impossibility, of establishing arbitrary standards for determining the causal relationship between the occupational exposure and the abnormal condition of the skin in every individual case.

"The lapse of time between exposure and examination, the inability to obtain an accurate history, the previous treatment, the combination of occupational and nonoccupational cutaneous disease and various other factors prevent the application of any criteria in certain cases. It is also realized that all the suggested criteria will not fit every individual case, that new causal factors will continually be introduced in industrial processes and that new, or at least unusual, manifestations on the skin may be caused by agents in use at the present time. However, a careful weighing of the evidence obtained by detailed history and examination in the light of these standards

are directly concerned with different state departments, and because of the close proximity of the chairman to Albany it is convenient and much more efficient to have personal interviews and thus save other members of the Committee long and often unnecessary trips. During the year reports have been made monthly to the Council and, because these reports are permanent records and in the office of the secretary, this report will include only unfinished business of the Committee and possibly some further information obtained regarding matters already reported.

Disposition of Registration Fees.—The Nassau County Medical Society presented the following resolution to the 1941 House of Delegates, whence it was referred to the Council for study, and thence to the Committee on Public Relations and Economics for study and report.

"WHEREAS, The Medical Practice Act of 1930 provides for the payment by every practicing physician of an annual re-registration fee of \$2; and

"WHEREAS, The medical profession was told at the time that this law was proposed that the purpose of the fee is to provide the educational authorities of the state with funds with which to control the unlawful practice of medicine in the state, with the implied or expressed promise that such fees were to be collected for a period of five years, by which time the problem of the control of unlawful practice of medicine was expected to be solved; and

"WHEREAS, This annual fee has been collected annually since the effective date of the new law, with no indication that it is not considered a permanent tax; and

"WHEREAS, There are no provisions or, at best, inadequate provisions for the care of indigent physicians in New York State; be it *Resolved*, First, that the Nassau County Medical Society requests an accounting of the moneys collected for annual re-registrations since the effective date of the law, with a statement as to how such moneys were expended; and be it further

Resolved, Second, that a sum of money be set aside from this fund to be made available to the indigent physicians of the state; and be it further

Resolved, That a portion of the annual registration be henceforth allocated for such purposes; and be it further

Resolved, That the delegates of the Nassau County Medical Society be instructed to present these resolutions to the annual meeting of the House of Delegates of the Medical Society of the State of New York to be held at Buffalo starting April 28, 1941, with the request that the Medical Society of the State of New York sponsor and see to the introduction and passage of such legislation as might be necessary to make effective the purposes of these resolutions.

Members of the Committee discussed the disposition of re-registration fees and also the question of fines for noncompliance with the law with Commissioners of Education Dr. Miller, Dr. Conroe, Dr. Heisler, and Dr. Hannon. The law is specific and requires every practicing physician to apply to the Department annually for registration. Application forms for such

registration will be mailed by the Department on or before the first day of October to every registered physician in the state. The application must then be filled out and returned to the Department with the statutory fee of \$2.00. The certificate of registration bears the date of January 1 and expires on December 31. The law further states that any licensed physician who fails or neglects to register by January 1 of any year, as required by the provisions of this section, shall be required to pay for registration, in addition to the fee of two dollars, a further fee of one dollar for each thirty days, or part thereof, that he is in default; and any licensed physician who willfully refuses or omits to register hereunder and engages in practice shall be subject to a civil penalty of one dollar for each day that such practice shall continue, and if the same continues for more than thirty days the penalty thereafter shall be five dollars per day so long as the said practice shall continue; said penalty shall be recoverable in an action by the attorney general of the state maintained in the name of the people of the state of New York.

The following letter from Director Heisler of the Division of Professional Licensure of the State Department of Education outlines the cost of the annual registration and the expense for the penal enforcement of the Medical Practice Act.

"Dr. Hannon has advised me that you would like to have information relative to the cost of the annual registration of physicians and the expenditures for the penal enforcement of the Medical Practice Act. I understand that you wish to ascertain whether the receipts from annual registration far exceed the expenditures for the enforcement, as has been asserted in some quarters, or whether they are insufficient to carry the load. Although it is impossible to make an exact financial statement, it can be shown that the latter is more nearly the case.

"In the first place, the receipts from the annual registration of physicians aggregate approximately \$50,000. During the past year, we have registered something over 24,000 physicians, each of whom has paid at least \$2 for his registration. In addition, we have additional fees for delay and delinquency which bring the total up to the amount stated.

"In determining the amount of the expenditures the problem is more difficult. Fortunately, some work along this line is being done under the direction of the Finance Division by Mr. Richard Woodruff, a graduate student of the Maxwell School of Public Administration at Syracuse University. From the data that he has collected, it appears that the annual cost of the permanent and temporary clerical staff having to do with the annual registration of physicians amounts to \$3,600. In addition there are unallocable services amounting to \$10,000. This amount represents the closest possible estimate of the value of the service rendered in the annual registration of physicians and in enforcement by members of the staff whose regular duties include much more.

"Mr. Woodruff has analyzed the service costs of the enforcement of the various professional laws by Mr. Mangan's office and advises me that the amount that best repre-

fications and should not be violated by any outside party, be he employer, insurance carrier representative, employers' organization representative, or labor union representative.

Laboratory Services.—Recently bills of practicing physicians have been questioned because they charged for laboratory services performed in a workman's compensation case where the laboratory tests were done by another physician.

Where a practitioner is qualified by reason of experience and training to do certain simple laboratory procedures himself, such as urine examinations and blood counts, and actually performs such examinations, he may include the cost of same in his bill. Where a physician orders laboratory service performed by a physician with laboratory qualifications, the latter should render the bill and not the attending physician who ordered the services. Where an attending physician sends a specimen of blood to the Department of Health Laboratory for a Wassermann test, it is not proper for him to charge a fee of \$5.00 for such test, since he does not actually perform the test. If the blood for a Wassermann is sent to a private laboratory, such laboratory, if licensed under the Workmen's Compensation Law, should make the charge for the Wassermann test.

Laboratory examinations under the Workmen's Compensation Law may be performed without authorization if they do not exceed \$10. Where the fee exceeds \$10, authorization should be obtained except in an emergency in accordance with the provisions of Section 13-a(5).

Aetna Casualty and Surety Company.—We are pleased to report that the Aetna Casualty and Surety Company has agreed to desist from its former practice of sending out names of physicians and hospitals to policyholders. This problem has been discussed in a number of our previous reports and has been the subject of considerable negotiation for a number of years. Mr. Samuel Kaltman, attorney for the Aetna, has informed us that the practice will cease as of March 1. We are very happy to announce a satisfactory conclusion of this matter and to congratulate the Aetna and Mr. Kaltman on their decision.

Miscellaneous Items.—There were five hearings before the Industrial Council on appeals by physicians over rulings on qualifications by the county medical society compensation boards. In each instance the compensation boards have been upheld.

We have been consulted on numerous occasions by the Chairman of the Compensation Law Board of the New York State Osteopathic Society, Dr. Claude M. Bancroft, who has always manifested a spirit of cooperation concerning workmen's compensation matters. The question whether osteopathic physicians may obtain specialists ratings in certain specialties has been raised and is being studied by your Committee.

Your Director has taken part in a number of programs on industrial medicine and surgery, and on compensation matters generally, before various county societies and private medical groups.

In the course of the year there were numerous conferences with the Industrial Board and the Industrial Council of the Department of Labor and also other law enforcement agencies, insur-

ance organizations, etc. Our relations with these groups continue cordial and harmonious.

Your Bureau has assisted county society compensation boards throughout the state in compensation matters and has assisted numerous physicians throughout the state in ironing out their difficulties in regard to compensation matters, payment of bills, etc.

As in the past, your Director has followed arbitration proceedings closely and participated in such arbitration proceedings upstate, as well as attending meetings of the legislative committee and secretaries group.

Appreciation.—Your Director wishes to acknowledge the great help voluntarily given by the Law Reform Committee of the Bar Association, under the chairmanship of Mr. Henry Clay Greenberg, in preparing and introducing certain amendments to the Workmen's Compensation Law to facilitate the administration of the Law.

During the past year our relations with the Department of Labor and the Compensation Insurance Rating Board have been close and cordial. We wish to express our appreciation and thanks to the rank and file of these organizations, especially to Mr. Henry S. Sayer, Mr. Irving Sofferman, and Miss Elizabeth Doogan of the Compensation Insurance Rating Board; and to Mr. Michael Murphy, Mr. Ralph R. Boyer, and Mr. Hugh Murphy of the Labor Department; as well as to the members of the Industrial Council. These individuals and an increasing number of representatives of insurance carriers organizations and self-insurers have shown a real desire and willingness to cooperate with your Committee and with the representatives of the county societies in bringing about a smoother and more equitable administration of the Workmen's Compensation Law.

Time and space do not permit of a detailed description of the routine work of the office. The volume of paper work has increased so that at the present time the office is working to capacity and occasionally overtime. Your Director wishes to commend and thank the members of the office staff under the supervision of Miss Elizabeth Wheeler for their devotion to their duties during the past year.

PART X

Public Relations and Economics

The Council Committee on Public Relations and Economics:

Augustus J. Hambrook, M.D., *Chairman*. Troy
Herbert H. Baucus, M.D. Buffalo
Harry Aranow, M.D. Bronx

has continued its studies of a number of different matters. The annual report on these, approved by the Council, follows.

REPORT

The Committee held three meetings during the year, at which matters referred to it by the Council were discussed and principles formulated. Because of the difficulty in bringing members of the Committee together at frequent intervals, much of the work was done by mail, telephone, and personal interviews by the chairman.

During the year many matters come up that

vehicle licenses. The family doctor can render valuable help to the Motor Vehicle Department of the state. The Commissioner stated that he had received no adverse comments on the special M.D. license plates accorded members of the medical profession, and he will continue to accord members of the medical profession this special privilege in the future. Physicians are cautioned to use on their cars only the license plate issued by the department. Any other plate is illegal. The medical insignia may be used on the front of the car and will accord traffic officers information as to the profession of the driver approaching him. This suggestion was made by the motor vehicle commissioner to obviate unnecessary traffic delays.

Physical Examinations for Federal Civil Service.—Some protests have been received and investigated by this Committee, wherein applicants for civil service positions have been required to have physical examination by a government-employed physician. I am informed, as of this date, that this has been changed and any licensed physician may now make such examinations and submit report. Hitherto, physicians in government institutions or under government pay made such examinations without cost to the applicant. In some instances excessive fees were requested by the examining physician. The stress of war may make necessary many changes in the way in which examinations are required and in the personnel. This Committee will continue to supervise such examinations.

Recommendations for the Improvement of the Coroner System in New York State. Better Postmortem Examinations.—The New York State Association of Public Health Laboratories and the New York State Association of Funeral Directors are both concerned with possible amendments to the law governing the duties of coroners. It will be noted that under this title you will find nowhere in the statutes a statement as to the qualifications or educational background which an individual must possess in order to be eligible for election to the position of coroner. In the State of New York some counties have abolished the position of coroner and substituted therefore a new position under the title of medical examiner. The administration of this new office has resulted in the appointment of persons who possess more adequately the proper qualifications for the important duties devolving upon the official. In the counties where the coroner still exists, it has been found that in some cases they do elect physicians, but in many other cases a layman holds the office. This requires that when an autopsy or post-mortem examination is required, it is necessary that the lay official call in to assist him a qualified physician. There exist today no specifications under the law as to experience or training necessary for the office of coroner. Almost any citizen can qualify for the position. The coroner is elected or appointed and in some instance he may exercise great power in a county.

Obviously, under our present type of civilization, the position of coroner has been outmoded. Such an officer should be a pathologist, trained in morbid pathology. He should have judicial temperament and be a good executive. At times even a well-trained and experienced pathologist

finds it difficult to determine the cause of death. How much more difficult does the problem become when a man without any experience makes this attempt. A coroner should also have legal knowledge and training. Many states have recognized this situation and have either abolished the office of coroner entirely or have delegated the duties to other county officials, such as the district attorney. In this state, medical examiners have replaced the coroners in at least four counties. In the few counties where medical examiners have been substituted for coroners, the administration of the new office has been improved. Any special tissue examinations or other laboratory investigation must be performed at a laboratory and by qualified laboratory men. The time seems to be at hand, therefore, when some change should be made, and the following recommendations are suggested:

1. That the position of coroner be abolished and the title of medical examiner with proper statutory requirements be substituted.
2. If this recommendation does not meet with the full approval of the electors in any county, then it is suggested that the person nominated for the position of coroner be required to have a physician's license to practice in this state. Further qualifications would be the ability correctly to perform autopsies and postmortem examinations.

The funeral directors are chiefly concerned with the manner in which postmortem examinations are made, and in many instances it has come to the attention of members of this Committee that postmortem examinations have been refused by a family on the advice of the funeral director. His objections were based on the fact that the examination was so poorly done that it made his care of the body unsatisfactory. Severed blood vessels were cut too short, ligatures slipped off, and this made embalming of the body unsatisfactory. The Subcommittee on Hospitals will cooperate with the funeral directors in efforts to have more satisfactory work done. Hospitals receive their rating in no small measure on post-mortem examinations performed, and for this reason alone members of the medical profession should take a vital interest in this matter. We have a fine opportunity at the present time to cooperate with the State Association of Funeral Directors and the New York State Association of Public Health Laboratories in correcting abuses that apparently now exist.

PART XI

Special Matters

During the year the Council has given attention to a wide variety of subjects of administrative or other special import. These matters and the actions thereon are herewith submitted.

State Society Assessments and Service in Armed Forces.—At your last meeting you gave direction "that, on the request of any component county medical society, the annual assessment of any of its members temporarily on active duty in the military or naval service of the United States may be remitted by the Council in full or in part during the period of that service."

sents the cost of enforcement in medicine is \$29,000.

"Annual registration requires a large amount of printing. The Publication Bureau advises me that these costs amount to approximately \$5,000. The printed list, appearing annually, costs by itself over \$4,700.

"In addition, there is a large expenditure for postage, amounting to over \$1,000, for sending out the application cards and the registration certificates, to say nothing of the large amount of correspondence that registration and enforcement require inevitably.

"This makes a grand total of \$48,600, but the story is by no means all told. There are intangibles and incalculables that would raise this amount to a much higher figure were it possible to compute them. For example, there is overhead. There is no possible way of computing the amount that should be charged to medical registration for items such as rent, heat, light, and janitor service. There is no way of computing how much medical registration should be charged for telephone service, messenger service to and from the mailing room, and the service in the Finance Division where the mail is opened and the fees are recorded. There is no way of computing the charge for building service and maintenance, equipment and supplies, depreciation, and other items. Undoubtedly, all of these items would amount to a considerable sum, and it would be unfair and inaccurate not to consider them in determining whether the medical profession pays in registration fees an amount that would be sufficient to carry on registration and enforcement as a separately housed and self-contained unit.

"The conclusion is inescapable. The state does not make a handsome profit or any profit at all on the annual registration of physicians. In fact, it is only by providing the cost of the incalculable items from other sources that the state has a sufficient amount left in the registration funds to carry on the vigorous enforcement of the law that its policy demands."

Fines for Late Registration.—The Committee has been active during the year in efforts to have fines imposed for late registration remitted. The department is anxious to cooperate but the law is specific and ignorance or neglect of its provisions is no excuse. The large proportion of the medical profession in the state register promptly and the publications department has agreed to print boxed information in the JOURNAL regarding annual registration. The county medical societies will be stimulated either through their publications or at meetings to have their membership register promptly and according to law. The names of all physicians going into service will be submitted to the department promptly and carried on the roster during their absence from their medical practice. The Committee has found very active cooperation on the part of all members in the department concerned, and has been aided in its work by Dr. Joseph Lawrence, our executive secretary.

We had hoped to include in this report a statement as to the enforcement of the Medical Practice Act by the Department of Education during the past year, but up to date no report has

been received and this information will be included in a supplemental report.

Health and Accident Insurance for Interns.—It was brought to the attention of the Council that in many instances in this state doctors serving as interns in hospitals were not covered by insurance, either accident or sickness. At the time no subcommittee on hospitals was available and this Committee instituted an investigation. Many of the hospitals were contacted by letter and the results were compiled. In many cases doctors served as interns without any compensation, while in some hospitals, especially upstate, some compensation is received for services rendered. In the course of their work accidents may occur and they may become sick by caring for patients in the wards of the hospital.

As a rule, nurses are covered under the State Compensation Law, and it seems only fair and reasonable that interns in hospitals should be protected under the Compensation Law. Dr. David J. Kaliski, director of the Workmen's Compensation Bureau of the State Medical Society, advises us that under Group 15 of the Workmen's Compensation Law, interns are covered in municipal hospitals, prisons, reformatories, mental hygiene hospitals, or a hospital maintained by any subdivision of the state.

In the case of *Bernstein v. Beth Israel Hospital*, 236 N.Y. 268; 133 S.B. 42, it was held by the court that an intern in a voluntary or private hospital is an employee of such an institution and therefore covered under the law. It would seem that all interns should be protected under the State Compensation Act and the newly created Subcommittee on Hospitals has been furnished with all data collected up to date. The new committee will have the responsibility of dealing with the Hospital Association and will, no doubt, make a report.

Medical Examination of Motor Vehicle Drivers.—After careful study covering several years, this Committee made definite recommendations last year to the Motor Vehicle Department of the state in connection with licenses and relicenses to be issued. It was found that accidents were caused repeatedly by the same drivers and some of these accidents were directly due to diseased condition or physical deficiencies—heart disease, diabetes, mental disease, nephritis, physical deformities. All were found to be associated with the accident repeaters. Because of the great number of motor vehicle drivers in the state, it would not be practical to have a yearly physical examination before license is issued. Applicants are now required to answer certain questions regarding evidence of disease and whether proper treatment is being administered. After a serious accident the driver is usually expected to furnish satisfactory report of his ability to drive. The mental case now committed to a hospital will have his license taken up and returned to him only after satisfactory proof of his mental fitness. We have a law now covering the drunken driver. The department feels that the recommendations made by the Medical Society have been fruitful and is anxious for our further cooperation.

To repeat, it is the opinion of the Committee that in many instances of diseased condition known to physicians, individuals could be discouraged by their physicians from seeking motor

helped to educate the public on the evils of compulsory health insurance.

It has been evident that the women will really work when they are given a job and that they will be active in combating unfavorable legislation, whereas the men for the most part will do little or nothing in endeavoring to influence legislation. It is believed that the Legislative Committee will testify to this fact in that they have always had great difficulty in getting doctors to write telegrams or letters to legislators, whereas the women will do it readily.

It is realized that there has been some opposition to the Women's Auxiliary in the state, but it is believed that those counties which have active auxiliaries will testify to their usefulness and that the opposition has been largely from those counties which either do not have them or have inactive ones.

Another point that occurred to me after hearing Dr. Bauckus' report is that the Auxiliary might also be useful in spreading information about medical expense insurance organizations.

Continuation of Special Committees.—The Council recommends the continuation of the two special committees of the Society which were created by the House in 1940 and reappointed by it in 1941. These are the Publication Committee and the Committee on Office Administration and Policies, which work under the supervision of and report to the Council.

The Publication Committee has met regularly and effected production of the JOURNAL and the 1941-1942 edition of the *Medical Directory of New York, New Jersey, and Connecticut*, as shown in Part IV of the Council report. Its personnel has been: the general manager, Dr. Irving; the director of the Public Relations Bureau, Mr. Anderson; the literary editor, Dr. Redway; the treasurer, Dr. Dwight; and one trustee, Dr. Brennan, who was also chairman.

The Committee on Office Administration and Policies has held regular meetings throughout the year coincidently with those of the Publication Committee since many of the matters discussed were of mutual interest. Among these were included the following: assignment of members of the office staffs and evaluation of their duties; specific functions of the Society's secretary in his various capacities; salary adjustments in relation to living costs; renewal of contracts of certain officers; consultations with auditor's representatives; and various questions of routine which came within the province of this Committee, including possible retrenchments necessitated by reduction of income from dues. Its personnel has been: the general manager, Dr. Irving; the business manager of the JOURNAL and the *Directory*, Mr. Anderson; the literary editor, Dr. Redway; the treasurer, Dr. Dwight; and one trustee, Dr. Kosmak, who was also chairman.

The Council recommends that in continuing the two committees the House direct that the personnel be as follows:

For the Publication Committee: the general manager, the director of the Public Relations Bureau, the literary editor, the treasurer, and one member of the Board of Trustees to be appointed by the president of the Society after consultation with the chairman of the Board of

Trustees, in accordance with the resolution adopted by the House of Delegates in 1941.

For the Committee on Office Administration and Policies: the general manager, the business manager of the JOURNAL and the *Directory*, the literary editor, the treasurer, and one member of the Board of Trustees to be appointed by the president of the Society, after consultation with the chairman of the Board of Trustees, in accordance with the resolution adopted by the House of Delegates in 1941.

Nominations for State Positions.—On request for a nomination from the Bureau of Narcotic Control of the New York State Department of Health, the Council nominated Dr. Homer L. Nelms, Albany, to succeed himself as a member of the Advisory Board of the Bureau of Narcotic Control on July 1, 1941. On request for nominations from the executive secretary of the Committee of Grievances of the State Department of Education, the Council nominated the following to succeed themselves on January 1, 1942: Dr. Austin G. Morris, Rochester; Dr. George B. Broad, Syracuse. On request for a nomination from the secretary of the State Board of Examiners of Nurses for membership on the Nurse Advisory Council, the Council of the State Society nominated Dr. Aloney L. Rust, Malone, to succeed himself as of December 31, 1941.

Related Bills.—The Council recommends payment of the following bills for travel expense, which were not turned in until after expiration of the statutory thirty days and possible extension for ninety days more: Dr. Harry C. Guess, Buffalo, \$10.81, for train fare to the A.M.A. meeting as delegate in 1941; Dr. F. Leslie Sullivan, Scotia, \$20.59, for travel expense in December, 1941, to attend the meeting of the Subcommittee on Medical Relief in Rochester.

Proposition for the Economical Use of Medical Personnel.—One of the members of the Nassau County Medical Society, Dr. Arthur C. Martin, drew up and submitted to Dr. Louis H. Bauer a plan which Dr. Bauer brought to the Council. It was understood that this was the method pursued in England. It was considered by the Council and was ordered to be transmitted to the surgeons general of the army and the navy. It follows:

Under the conditions of this war, adequate medical, dental, and nursing service must be provided for: (1) the army and navy abroad; (2) the army and navy at home; (3) the war industry worker; (4) the civil population under normal peacetime sickness incidence; (5) the civil population as the potential victims of casualties resulting from invasion by air or sea, and from sabotage which may strike anywhere.

None of these three groups can safely be deprived of adequate and prompt professional service.

The number of men and women available who are trained and able to render this professional service is definitely limited. This number cannot be materially increased by any practical or safe method of rushed education or mass production.

Therefore, it is imperative that the services of already trained and competent medical practitioners be allocated with the most care-

In keeping with this policy your Council worked out and set up for the year 1941 the following guiding regulations which were sent to the county medical societies in June, 1941:

1. *Full remission* of 1941 state assessments will be made, when requested by the county medical societies, for those members temporarily in full-time or practically full-time military or naval service of the United States who entered such service prior to June 1, 1941, except as stated under No. 3 below.

2. *No remission* of 1941 state assessments will be made for those members entering service after June 1, 1941.

3. *For new members* elected in 1941 or elected in the last three months of 1940 with dues credited to 1941, *no remission* of the first year's assessments will be granted.

This decision rests on the reasoning that the payment of the first year's dues is made at the time of application and partakes somewhat of the nature of an initiation fee.

4. *1941 state assessments already received* from county medical societies for those members—not new members—eligible for remission of these assessments under No. 1 above will be *refunded* by the State Society to the county societies.

As a result of this action the Council, at request of the county societies, remitted state assessments for the year 1941 for members who had entered service prior to June 1, 1941, to the total of 455.

The matter of remission of state assessment for the year 1942 was taken up with the county societies with the break of the new year. So far (March 12, 1942), requests have come in covering two groups: first, those who had received 1941 remissions because of entrance into service before June 1, 1941; and, second, those who had gone into service after that date. The Council has granted 1942 remissions to the total of 581.

Further 1942 remissions will, of course, be in order for members in good standing with dues paid for 1941 who will enter service before June 1, 1942.

Two questions have arisen as to remissions: one of these the Council felt that it had the authority to settle, but the second question, in the opinion of the Council, requires action by the House of Delegates.

The Council went on record at its meeting on January 8, 1942, "as interpreting the action of the 1941 House on remissions for service to include remission for any member entering the armed services of the Allies of the United States in the present war. It was understood that remissions would be made on the same basis as for those entering the armed services of the United States."

The other question the Council refers to the House. It arose because the Cattaraugus County Medical Society proffered a request for remission of 1942 assessment for a member who gave up his practice in Olean, reporting for duty with the U. S. Public Health Service in the Panama Canal Zone. The wording of the resolution adopted by the House in 1941 specifically mentioned active duty "in the military or naval service of the United States." At the time of this report the Council is seeking information about wartime increases in the U. S. Public Health Service which in the ordinary course of

events would be followed by demobilization when the war ends. This will be presented at the time of the meeting.

Financial Aid to County Societies for Medical Preparedness Work.—At your last meeting you considered a resolution reading, "That the Medical Society of the State of New York allot sufficient funds to assist the county committees on medical preparedness where it is evident that such assistance is needed." After discussion this was committed "to the Council for such action as they may find expedient." The Council gave due consideration to this problem but decided last October to table the matter "until it has been determined just what the future of draft board work is going to be."

Woman's Auxiliary.—The Council set up an Advisory Committee to the Woman's Auxiliary, as a Council committee to replace the former Special Committee of the Society, with the following personnel:

Louis H. Bauer, M.D., *Chairman*.Hempstead
Francis R. Irving, M.D.Syracuse
Carlton E. Wertz, M.D.Buffalo

This Committee presented a report, which has the approval of the Council, including the recommendations.

REPORT

The Advisory Committee to the Woman's Auxiliary to the Medical Society of the State of New York had a meeting recently with the officers of the Auxiliary. A long-range program for the Auxiliary was discussed. It is felt that certain actions should be taken by the Council in the matter of the Auxiliary.

First, there are too few counties which have organized auxiliaries. It is believed that through the JOURNAL and through communication with the secretaries of the various county societies the Council should urge the formation of additional auxiliaries and urge those which already have them organized to increase their membership.

Second, it is felt that an increasing strain is going to be placed on the finances of many county societies due to the loss of dues from members entering the military services. In some instances this may prove such a financial drain that many society activities will have to be suspended unless another source of income is found. It is believed that the auxiliaries in many instances might be able to increase the finances of their county societies by raising money and by helping out in county society offices on a part-time basis, thereby reducing the overhead.

The third recommendation is that county societies be urged to have their auxiliaries make a survey of their membership. Many members will be found qualified as nurses, laboratory technicians, and clerical workers, and they could be tied not only into county society work but into the defense program. Some of the auxiliaries have already made such surveys and are anxious to have their membership put to work.

The final recommendation is that the Public Relations Bureau be asked to prepare a circular of information on the proposed extension of the Social Security Act to cover hospitalization and health. This circular can be used by Auxiliary members to help educate the general public through their connections with other organizations on the viciousness of this plan just as they

PART XII

Malpractice Defense and Insurance

The Committee on Malpractice Defense and Insurance:

Clarence G. Bandler, M.D., *Chairman*.....

.....New York

Murray M. Gardner, M.D.....Watertown

Andrew Sloan, M.D.....Utica

Peter Irving, M.D., *ex officio*.....New York

Kirby Dwight, M.D., *ex officio*.....New York

submitted the following report, which the Council approved.

REPORT

Great wars reach into and disturb the economic balance of every phase of human existence in all countries. It is not easy to trace the course by which some elements are disturbed, but the results are clearly discernible. It is easy to understand, for example, why marine insurance with its attendant war-risk losses is profoundly affected, but it is not so easy to understand why the general unrest should cause an increase in the cost of malpractice insurance, but our most carefully compiled loss tabulations indicate that to be a fact. While there has been a noticeable decrease in the number of suits and claims against members of the State Medical Society, the cost of disposing of them has considerably offset that favorable factor. The over-all result of the operation of the Group Plan of the State Society up to date indicates that some increase in the base rate has become necessary.

Analysis of our loss costs developed the fact that losses, on account of plastic surgery and particularly that which, for want of a better term, is referred to as "cosmetic" surgery, have grown to be far in excess of those for all other branches of medical practice, with possible exception of x-ray therapy. Had it not been for those losses, it is possible that a small reduction could have been made in the Group Plan rate at the present time.

This situation has made it necessary for the Yorkshire Indemnity Company to amend the master policy so as to exclude all losses on account of plastic surgery, except those arising by reason of the performance of operations for the purpose of "remedying conditions caused by trauma, or by congenital deformities, or by demonstrable pathological lesions." At the same time, arrangements were made so that members whose practice regularly includes "cosmetic" surgery, and who have clearly demonstrated their competence to pursue that specialty, could secure protection, by endorsement added to their individual insurance, for an additional premium equal to 50 per cent of their annual premium. This follows the principle, adopted in 1924 with respect to x-ray therapy, of allocating increased charges against specialties responsible for excessive loss experience.

Because of this adjustment, the forthcoming increase in the general rate will be small. Although the new rate computations have not yet been completed, it appears that some further reduction may be made in the expense element which will exert a further modifying effect upon the ultimate rate.

At the present time, when an increased number

of members are being called into active service with the armed forces, the following opinion of the Judge Advocate General of the Army will be of special interest:

"A person in the military service may claim that an officer of the medical corps has in some manner been guilty of malpractice in treating or examining him in the line of duty. A similar claim for alleged malpractice may be pressed against an examining physician for a local Selective Service board by a selectee called before that board. The fact that a person is in the military service, or is in the course of being inducted therein, does not prevent him from asserting his civil rights so long as the interests of the service or of national defense are not concerned. Hence, the Judge Advocate General of the Army has held that members of the Army are entitled to the same civil rights of action among one another with reference to suits for malpractice or negligence as they would have in civil life.*

"Without doubt the same degree of care, diligence, and professional ability required of any physician with respect to the care of patients in civilian life is required by law of a medical officer of the Army, or of an examining physician for a local board, in his care or examination of a member of the service or of a selectee called for the purposes of induction. For a departure from such standard resulting in harm to the patient the medical officer or the examining physician would be liable in a civil suit by the aggrieved patient the same as though both the patient and the physician were in civil life. The medical officer, then, in the Army and the physician acting for a local Selective Service board by virtue of his service or function stand in no different position with respect to answerability to his patients from that of a physician acting solely in a civil capacity.

"However, were a malpractice claim to be pressed against an army medical officer or an examining physician for a local board for alleged malpractice in the performance of his official duties, the government itself would no doubt provide defense for the physician accused. It has been the practice of the Attorney General, in the past, to provide, on the request of an interested government department or agency, defense for government officers or agents in civil suits arising out of the activities in the course of the discharge of their official duties. A communication from the office of the Judge Advocate General of the Army dated May 1, 1941, indicates that in the past the War Department itself has not undertaken the defense of a civil suit for malpractice brought against a member of the medical corps, but that the defendant medical officer has had the right to have the case removed to a federal court and to be defended by a United States attorney designated by the Department of Justice. If, however, according to this communication, a judgment was to be rendered against such a medical officer, there is no provision by law by which the judgment could be paid by the government or by which the defendant physician could be reimbursed by the government."

* J.A.G. 707, March 6, 1934.

ful consideration of the needs of the entire population.

To accomplish this "rationing" of medical service, it should be recognized that every practitioner has parts of each day in which he is not engaged in his professional duties. Further, it can be shown that by rearrangement of the routine work of each practitioner still more hours of each day could be set aside for duties other than are now engaged in.

This surplus time can be placed at the disposal of: (1) the army and navy at home; (2) the war industry worker; (3) the civil general population.

It may be accepted by the medical services of the armed forces, therefore, that much of the medical service required by them at home can be supplied by present active practitioners on a part-time basis, without removing these practitioners from their present localities. They may recognize that the clinical care of the sick and wounded in permanent home hospitals and camps differs little from the clinical service now being rendered to civilians in civil hospitals, and further that in case of air or invasion casualties all the population, military and civil alike, are reduced to a common level and must all be treated alike. It is entirely possible to enrol the whole eligible medical, dental, and nursing personnel of the United States into a tremendous reservoir of "professional service hours."

From this reservoir, withdrawals could be made in the following major classes:

1. Young, physically fit practitioners for the physically arduous requirements of over-sea and ship service, full-time;

2. Certain others, regardless of age and not necessarily physically perfect, for special, full-time, administrative consultative command, or other duties which require medical or dental training;

3. The great majority of the several professions to be called to give service, part of their time, to registration areas, camps, concentration centers, embarkation centers, and base and general hospitals in the "home area" (continental United States) without removal from their home communities or severance from their civilian practices.

Suggested Method of Creating, Rapidly and Effectively, this "Reservoir of Professional Service Hours."—Establish a federal Professional Reserve Corps composed of (1) doctors of medicine, (2) dentists, and (3) trained nurses. Enrol therein every active and acceptable practitioner of these medical and allied professions in the United States, regardless of age or physical condition, through the national, state, and county organizations. Classify the whole group of such practitioners in accordance with the major classes previously outlined. As rapidly as may be needed, release for active over-sea service the present full-time medical officers in now existing "home area" army and navy hospitals, camps, centers, etc., replacing them with local, part-time practitioners of the third group.

As new army and navy hospitals are contemplated, locate them with principal regard to the availability of local practitioners of the third group.

Protest against Noninclusion in Directory.—From an active member who is not registered to practice in the State of New York, but has membership through the Medical Society of the County of New York as a full-time teacher in the Cornell University Medical College, comes a protest that the Council deems can best be considered by the House of Delegates. The following letter is from Dr. McKeen Cattell, professor of Pharmacology at Cornell, and resident in New York City. He has been an active member since January 24, 1938.

"For several years I have been carrying cards which certify that I am a member in good standing of the Medical Society of the County of New York and of the Medical Society of the State of New York. During this period my name has not been included in the *Medical Directory of New York, New Jersey, and Connecticut*. Evidently the membership is made up of sheep and goats. There would seem to be no objection to this, but somewhere there should be available a complete listing of the membership of the Society which is accessible for reference. If it is not feasible to include all the members in a single listing, the disqualified members should be classified under a separate heading.

The present policy is misleading and a source of frequent embarrassment to me. I am therefore writing to request that the matter be rectified with the publication of the next edition of the *Directory*."

The reason for nonpublication of Dr. Cattell's name is the policy laid down many years ago of listing in the *Directory* only physicians who have registered their licenses to practice in the state of New York. The House alone, therefore, has authority to change that policy—if a change be deemed wise.

Committee for Interpretation of Medical Ethics.—The Council, as instructed, considered "an amendment to our constitution setting up a body for interpretation of medical ethics, to which committee questions could properly be addressed."

The Council is of the opinion that the objective stated does not call for amendment of the constitution. It is the belief of the Council that where questions come from members on matters of ethics, they should be referred directly to the county society concerned. This conclusion rests on the fact that while the *Principles of Professional Conduct* are a product of the state Society's studies, their application is primarily the privilege and duty of the county societies, with the state Society ready to act as a court of appeals.

Where questions come from county societies, they should come to the Council—with, if necessary, a Council committee to sift them through and thus hasten reply.

1945 Convention of the American Medical Association.—From the New York Convention and Visitors' Bureau, the Council has received a suggestion that the American Medical Association be invited by the Medical Society of the State of New York to hold its annual meeting in 1945 in New York City. The Council begs to transmit this suggestion without recommendation.

committee which recommended adoption of the resolution has been headed. That committee felt "that the Council and elected officers should at all times be cognizant of any impending legislation and be on the alert to study the same."

Deaf and Hard of Hearing (Section 47).—Recommendation was adopted that the Council committee concerned with studies of problems in the field of the Deaf and Hard of Hearing be continued.

The Council continued the committee and increased it to five. See Part II of the 1942 Council Report for report on the committee's work this year.

Deferment of Service for Medical Students (Section 62).—With relation to medical students already inducted (at that time) into the Army, the House passed the following resolution:

"WHEREAS, the experience of belligerent nations in the World War and in the present conflict amply demonstrates the necessity for insuring a continuing supply of well-trained medical graduates; and

"WHEREAS, the United States Army in 1917-1918 permitted medical students on active service to be transferred to the Reserve for the purpose of completing their medical course, on application to and approval by the Surgeon General; therefore be it

"Resolved, that the Medical Society of the State of New York instruct its delegates to the American Medical Association to introduce a resolution, memorializing the Surgeon General to give consideration to similar action with respect to medical students inducted into active service in the present emergency."

The matter was presented in a resolution to the House of Delegates of the American Medical Association on June 2, 1941.

(Section 63).—For medical students not yet (at that time) inducted, the House approved of the principle of deferment of service for medical students and enrolled medical students as "essential to the health, safety or interest of the nation."

This matter also was presented to the House of Delegates of the American Medical Association on June 2, 1941.

Directory (Section 39).—Recommendation was adopted that a return be made to the old system of listing the names by towns so "that New York City and each of its boroughs be listed alphabetically after Manhattan, and grouped in the front of the Directory."

This instruction was carried out in the 1941-1942 edition of the *Medical Directory of New York, New Jersey, and Connecticut*. See Part IV of the 1942 Council Report.

The House also adopted a recommendation "that the *Directory* be alphabetically thumb-indexed or, if this is too expensive, that some method be evolved and included in the new *Directory* of rendering the alphabetical listing of physicians and communities more easily available."

This procedure was found too expensive by the Publication Committee and the instruction,

therefore, was not carried out. See Part IV of the 1942 Council Report.

"Doctor"—Use of Title (Section 77).—The House approved the following report of the reference committee concerned:

"Your committee approves of the stand of the Committee on Legislation to safeguard the use of the title of 'Doctor' by those who practice podiatry, and that measures be taken to enact legislation to limit the term 'Doctor' to those who deserve it without qualifying terms."

The Council took this under consideration but took no action looking to further legislation. It was understood that under present laws of the state the only one who may use the title "Doctor" is a Doctor of Medicine. All other "doctorates" now require the qualifying terms of Doctor of Philosophy, Podiatry, etc.

Dues and Assessments—Remission for Members in Active Military and Naval Service (Section 56).—The House, being advised of the action of one component county medical society (Erie County) as favoring the waiving of both county society dues and State Society assessments, went on record as follows:

"that, on the request of any component county medical society, the annual assessment of any of its members temporarily on active duty in the military or naval service of the United States may be remitted by the Council in full or in part during the period of such service."

The Council, with regard to State Society assessments, worked out a system of making remissions, and put it into practice as shown in Part XI of the 1942 Council Report.

Governor and Legislators—Expression of Appreciation (Section 51).—The House adopted "an expression of appreciation to the members and officers of the Legislature, and especially to the Governor, for the courteous reception extended representatives of the medical profession and the thoughtful consideration they have given medical and public health measures that have come before them."

The following letter was sent, under Council authority, to the Governor over the signatures of the president and of the secretary:

May 5, 1941

Hon. Herbert H. Lehman
Governor of the State of New York
Albany, New York

Dear Sir:

It gives us great pleasure to advise you that the Medical Society of the State of New York at its recent Meeting on April 28, 1941, adopted a resolution expressing appreciation to the members and officers of the Legislature, and especially to the Governor, for the courteous reception extended the members of the medical profession and the thoughtful consideration given medical and public health measures that have come before the Legislature and yourself.

Respectfully yours,
SAMUEL J. KOPETZKY, M.D.
President
PETER IRVING, M.D.
Secretary

Malpractice insurance in the Society's Group Plan will extend protection to policyholders *wherever they may be*. It will also protect members on account of suits against them because of the acts of other insured members in whose care they leave their practice.

Malpractice defense, however skillful, is only half of the protection needed by a practicing physician in this state, because not all suits or claims are resolved in favor of the defendants. A few are lost, but many are compromised because they are of such a nature that public defense would do more harm to the doctor's standing in his community than would a quiet settlement out of court. In such cases in New York State, an uninsured doctor must bear the cost of settlement and all expenses incident to defense except, of course, fees for legal counsel.

Malpractice protection to be effective must combine sound indemnity and skillful legal defense. That is the great lesson learned by the State Medical Society following the last war. It was to provide such a combination that the Group Malpractice Insurance Plan was organized by the Society in 1921. And since, for the first

time in insurance or medical history, these two elements of protection were brought together under the supervision and direction of organized medicine the Group Plan has lived and grown stronger through each of its twenty years of existence. As this plan of ours approaches its twenty-first birthday, it can be said that no undertaking of the State Medical Society has accomplished more for its members.

It has furnished sound, safe, and reliable financial protection. It has maintained, with the help of the Society, the finest legal defense for doctors to be found any place in the world. It has made possible the continuance of free malpractice defense for uninsured members of the Society. It has relieved the members from worry on account of malpractice actions against them and allowed them to devote their full thought and energies to their professional work, with no haunting fear of a courtroom. Since every member of the Medical Society of the State of New York, whether insured or not, benefits by the existence and sound growth of the Group Plan, every member of the Society owes to it his loyal backing and support.

Resumé of Instructions of the 1941 House of Delegates and Actions Thereon of Council, Trustees, and Officers

At the 1940 meeting the House of Delegates adopted a resolution to the effect "that the Annual Reports of the Medical Society of the State of New York in matters referred to the Officers, Trustees, or Council for action or study by the preceding House of Delegates shall include a résumé of the recommendations and resolutions with a definite report as to the specific action in each instance."

There follows what is in effect a summary, of index type, of the different instructions issued by the House at its meeting on April 28 and 29, 1941. The significant portions alone of the different resolutions are quoted.

The term "section" with a number following each heading refers to the Minutes of the 1941 House published in the June 15 and July 1, 1941, issues of the NEW YORK STATE JOURNAL OF MEDICINE.

—PETER IRVING, M.D., *Secretary*

Advertising by Physicians in Newspapers (Section 61).—

"Resolved, that the House of Delegates of the Medical Society of the State of New York go on record as disapproving all advertising in newspapers by practicing licensed physicians of the State of New York, individually or in groups, in the form of announcing their office address, office hours, kind of practice or particular cure to the public; and further be it

"Resolved, that the House of Delegates instruct the Committee on Legislation of the New York State Medical Society to take any necessary action to amend the present law to this effect."

This instruction was passed by the Council to its Committee on Legislation.

Committee on Public Health and Education (Section 46).—The House expressed "the hope that means may be found providing greater support in funds and personnel" for the Council Committee on Public Health and Education.

The Council and Trustees appropriated an initial increase in funds for this work in the budget for the last half of the calendar year 1941. For the new fiscal year 1942 the total allowance was enlarged to, roughly, 50 per cent more. This takes care of several new needs, including those caused by the substantial increase in number of subcommittees.

Corporate Practice of Medicine (Section 71).—The House adopted the following resolution:

"WHEREAS, the practice of medicine or of any other profession by a corporation is advisedly prohibited by most of the states of the Union; and

"WHEREAS, New York State now authorizes the formation of nonprofit corporations in the field of voluntary health and medical expense insurance, a development which may ultimately be extended to the authorization of the virtual practice of medicine by commercial as well as nonprofit corporations; and

"WHEREAS, proponents of radical innovations in the practice of medicine are known to be seeking means of breaking down or of circumventing present legal obstacles to the outright or disguised practice of medicine by corporations; therefore be it

"Resolved, that the House of Delegates request the Council to designate a committee to study the present laws and precedents in New York State relating to the corporate practice of medicine; this committee to be charged with the continuing duty of studying and periodically reporting to the House of Delegates and to the Society its findings and recommendations, with a view to preventing the destruction or circumvention of legal safeguards against corporate practice in New York State."

This was referred to the Council Committee on Public Relations and Economics. No report has been prepared but the advice of the reference

Medical Ethics Committee (Section 77).—Report of reference committee adopted included the following:

"The committee urges the Council to consider an amendment to our constitution setting up a body for the interpretation of medical ethics, to which committee questions could properly be addressed."

See Part XI of Council Report for report on Council study.

Medical Licensure to Graduates of Foreign Medical Schools (Section 75).—

"Res.

"1.

New Y

otherwise and irrespective of the question of citizenship, of graduates of foreign medical schools be strictly in accordance with the method of recognition that is applied with respect to the graduates of medical schools located in the United States and Canada. Any other method of recognition would constitute the grossest type of discrimination in favor of foreign graduates;

"2. That in the future recognition be accorded graduates of a foreign medical school who apply for license to practice medicine in the State of New York, only when there is in the possession of the Department evidence of the quality of instruction imparted by the school of graduation. This must be of equal quality with the evidence required of approved domestic schools. The identical standard should be applied in approving all medical schools, domestic or foreign."

The stand thus taken was ordered brought to the attention of the Executive Officer of Education through the Executive Officer.

Medical Preparedness—Funds to Assist County Societies (Section 74).—A resolution was ordered committed to the Council "for such action as they may find expedient." The resolution reads:

"That the Medical Society of the State of New York allot sufficient funds to assist the county committees on medical preparedness where it is evident that such assistance is needed."

The Council in October, 1941, postponed action until the future status of draft board work should be determined. See Part XI of Council Report.

Medical Practice Act—Definition of Word "Antiseptic" (Section 41).—Resolution adopted and ordered presented to the Board of Regents of the University of the State of New York:

"WHEREAS, the word 'antiseptic' has never been clearly defined as used in the Medical Practice Act, Paragraph 2, Section 1262; be it

"Resolved, that for the purpose of administration the term 'antiseptic,' as used in this law, shall be construed to refer to a substance employed for external purposes, the effect in both instances being to prevent or inhibit the growth of microorganisms."

This resolution was presented to the Regents. In December the Executive Officer reported to

the Council that in the opinion of the Attorney General the definition cannot be used legally since no State Department's jurisdiction permits it to interpret the law in such fashion as to grant less than the law itself; that no definition of antiseptic as given in the dictionary or encyclopedia limits its use to external application; the only way in which the definition of the House could be put in operation would be to have it incorporated in the law.

The Legislation Committee still has this under study.

Medical Practice Act—Enforcement and Re-registration Fees (Section 47—Enforcement).—Recommendation adopted: "that further annual reports on the workings of the Medical Practice Act be made to the House of Delegates from year to year."

See Section X of Council Report for this year's report on enforcement.

(Section 48. Re-registration Fees—Disposition) A resolution was referred to the Council for study. It read:

"WHEREAS, the Medical Practice Act of 1930 provides for the payment by every practicing physician of an annual re-registration fee of \$2; and

"WHEREAS, the medical profession was told at the time this law was proposed that the purpose of the fee is to provide the educational authorities of the state with funds with which to control the unlawful practice of medicine in the state with the implied or expressed promise that such fees were to be collected for a period of five years by which time the problem of the control of unlawful practice of medicine was expected to be solved; and

"WHEREAS, this annual fee has been collected annually since the effective date of the new law with no indication that it is not considered a permanent tax; and

"WHEREAS, there are no provisions or, at best, inadequate provisions for the care of indigent physicians in New York State; be it

"Resolved, first, that the Nassau County Medical Society requests an accounting of the monies collected for annual re-registration since the effective date of the new law with a statement as to how such monies were expended; and be it further

"Resolved, second, that a sum of money be set aside from this fund to be made available to the indigent physicians of the state; and be it further

"Resolved, that a portion of the annual re-registration be henceforth allocated for such purposes; and be it further

"Resolved, that the delegates of the Nassau County Medical Society be instructed to present these resolutions to the annual meeting of the House of Delegates of the Medical Society of the State of New York to be held at Buffalo starting April 23, 1941, with the request that the Medical Society of the State of New York sponsor and seek the introduction and passage of such legislation as might be necessary to make effective the purposes of these resolutions."

The Council in Part X reports fully on its study of this matter.

Instead of sending individual letters to the members and officers of the Legislature, the Council authorized that thanks be extended through an editorial in the JOURNAL. The editorial, from the June 1, 1941, issue of the JOURNAL (p. 1144) follows:

See Your Legislators

The House of Delegates at the One Hundred and Thirty-fifth Annual Meeting of the Medical Society of the State of New York voted unanimously "to adopt an expression of appreciation to the members and officers of the Legislature, and especially to the Governor, for the courteous reception extended to the representatives of the medical profession and the thoughtful consideration they have given medical and public health measures that have come before them."

Legislators are not mindreaders, however disposed they may be to cooperate with their constituents and with the medical profession. They are not mindreaders but lawmakers. To make laws wisely they must be accurately informed. And especially is this true concerning matters medical since such matters are frequently highly technical.

It is, therefore, up to the doctors of medicine who know about these things to keep closely in touch with their representatives not only in Albany but in Washington also. Cooperation implies equal effort on both sides. No legislator can cooperate with an indifferent, silent, or uncommunicative profession. Let every member of this Society get in contact with his representative or senator often. This is an obligation that medicine will neglect at its own peril and that constitutes a disservice to the public.

Hospital Construction Federal Bill S. 1230 (Section 45).—The House adopted a resolution which it had received from the Kings County Medical Society and revised in part to read:

"The Medical Society of the State of New York is informed that the Senate Committee on Education and Labor, of which Senator Mead is a member, has under consideration S. 1230, the Hospital Construction Bill introduced by Senator Brown of Michigan. The Society, through its proper committee, has carefully studied the bill and wishes to file with Senator Mead certain objections to it in its present form:

(1) It objects to the inclusion of an osteopath on the National Hospital Advisory Council. This designation seems unnecessary, for no hospital would be created for that form of treatment alone since it is only a specialized form of treatment.

(2) The bill seems to provide that only projects constructed within the first year shall be supervised by the advisory council. Other projects conceivably will be constructed in later years and the advisory council's authority should be extended to cover these also.

(3) The definition of the term 'hospital' in Section 18 is so worded as to permit of the construction, equipment and operation of health, diagnostic and treatment centers without specifying that there must be available bed capacity. Such centers, we believe, without available bed capacity would not constitute a hospital."

The Council directed Dr. Lawrence, the executive officer, to carry out the instruction to register the objections of the Society to the bill.

Interns—Health and Accident Insurance (Section 42).—The House received a suggestion that legislation be introduced "making it obligatory for hospitals in New York State to provide health and accident insurance for interns serving in their hospitals."

This matter was referred by the Council to its Committee on Public Relations and Economics. See Part X of the 1942 Council Report for action taken.

Invitation to American Medical Association for 1944 Meeting in New York City (Section 70).—The House authorized an invitation to the American Medical Association to hold its 1944 Meeting in New York City.

The invitation was given officially and by the delegates from the State Society. The decision of the A.M.A. House was for St. Louis in 1944.

Laboratory Medicine (Section 55).—In 1940 the House adopted the resolution:

"Be It Resolved That:

"1. The House of Delegates go on record as disapproving laboratory medicine by laymen or nonmedical personnel;

"2. That measures for establishing a proper relationship between city and state departments of health laboratories and physicians who practice pathology be endorsed;

"3. That the work of state and city departments of health be limited to the diagnosis of communicable diseases except where the diagnostic facilities of the state and city health departments are the only diagnostic means available for indigent patients."

In 1941 the House, receiving a report that conferences with representatives of various organizations on this resolution had turned up differences of opinion, adopted a recommendation "that the Council committee continue conferences looking toward the practical adoption of the spirit of the resolution by the laboratories concerned."

Formal conferences have not been held as yet.

Laboratories—Public Health (Section 55).—Recommendation: "Adoption of the principles stated in the proposal and appropriate action thereon by county medical societies and laboratory directors throughout the state." (See proposals in the JOURNAL for April 1, 1941.)

Formal meetings have not been held but there has been frequent informal contact with representatives of the Department of Health and of the Public Laboratories in the state, through the Council Committees on Public Health and Education and on Public Relations and Economics.

Library Fund (Section 56).—Recommendation: "the creation of a fund for a library in order to facilitate the work of the Publication Committee should be referred to the Council for study and action."

The Council delegated this study to the Publication Committee, which has not as yet made a final report.

Manhattan State Hospital—Demolition (Section 55).—The Council was charged with continuing observation of the opposed plan for early demolition of the hospital.

No action has been necessary.

Medical Ethics Committee (Section 77).—Report of reference committee adopted included the following:

"The committee urges the Council to consider an amendment to our constitution setting up a body for the interpretation of medical ethics, to which committee questions could properly be addressed."

See Part XI of Council Report for report on Council study.

Medical Licensure to Graduates of Foreign Medical Schools (Section 75).—

of Delegates:
medical licensure in
New York State whether after examination or

uates of medical schools located in the United States and Canada. Any other method of recognition would constitute the grossest type of discrimination in favor of foreign graduates;

"2. That in the future recognition be accorded graduates of a foreign medical school who apply for license to practice medicine in the State of New York, only when there is in the possession of the Department evidence of the quality of instruction imparted by the school of graduation. This must be of equal quality with the evidence required of approved domestic schools. The identical standard should be applied in approving all medical schools, domestic or foreign."

The stand thus taken was ordered brought to the attention of the State Department of Education through the Secretary and Executive Officer

Medical Preparedness—Funds to Assist County Societies (Section 74).—A resolution was ordered committed to the Council "for such action as they may find expedient." The resolution reads:

"That the Medical Society of the State of New York allot sufficient funds to assist the county committees on medical preparedness where it is evident that such assistance is needed."

The Council in October, 1941, postponed action until the future status of draft board work should be determined. See Part XI of Council Report.

Medical Practice Act—Definition of Word "Antiseptic" (Section 41).—Resolution adopted and ordered presented to the Board of Regents of the University of the State of New York:

"WHEREAS, the word 'antiseptic' has never been clearly defined as used in the Medical Practice Act, Paragraph 2, Section 1262; be it

"Resolved, that for the purpose of administration the term 'antiseptic,' as used in this law, shall be construed to refer to a substance employed for external application only, or to serve as a solution for the sterilization of instruments, the effect in both instances being to prevent or inhibit the growth of microorganisms."

This resolution was presented to the Regents. In December the Executive Officer reported to

the Council that in the opinion of the Attorney General the definition cannot be used legally since no State Department's jurisdiction permits it to interpret the law in such fashion as to grant less than the law itself; that no definition of antiseptic as given in the dictionary or encyclopedia limits its use to external application; the only way in which the definition of the House could be put in operation would be to have it incorporated in the law.

The Legislation Committee still has this under study.

Medical Practice Act—Enforcement and Re-registration Fees (Section 47—Enforcement).—Recommendation adopted: "that further annual reports on the workings of the Medical Practice Act be made to the House of Delegates from year to year."

See Section X of Council Report for this year's report on enforcement.

(Section 48. Re-registration Fees—Disposition) A resolution was referred to the Council for study. It read:

"WHEREAS, the Medical Practice Act of 1930 provides for the payment by every practicing physician of an annual re-registration fee of \$2; and

"WHEREAS, the medical profession was told at the time this law was proposed that the purpose of the fee is to provide the educational authorities of the state with funds with which to control the unlawful practice of medicine in the state with the implied or expressed promise that such fees were to be collected for a period of five years by which time the problem of the control of unlawful practice of medicine was expected to be solved; and

"WHEREAS, this annual fee has been collected annually since the effective date of the new law with no indication that it is not considered a permanent tax; and

"WHEREAS, there are no provisions or, at best, inadequate provisions for the care of indigent physicians in New York State; be it

"Resolved, first, that the Nassau County Medical Society requests an accounting of the monies collected for annual re-registration since the effective date of the new law with a statement as to how such monies were expended; and be it further

"Resolved, second, that a sum of money be set aside from this fund to be made available to the indigent physicians of the state; and be it further

"Resolved, that a portion of the annual re-registration be henceforth allocated for such purposes; and be it further

"Resolved, that the delegates of the Nassau County Medical Society be instructed to present these resolutions to the annual meeting of the House of Delegates of the Medical Society of the State of New York to be held at Buffalo starting April 28, 1941, with the request that the Medical Society of the State of New York sponsor and seek the introduction and passage of such legislation as might be necessary to make effective the purposes of these resolutions."

The Council in Part X reports fully on its study of this matter.

Instead of sending individual letters to the members and officers of the Legislature, the Council authorized that thanks be extended through an editorial in the *JOURNAL*. The editorial, from the June 1, 1941, issue of the *JOURNAL* (p. 1144) follows:

See Your Legislators

The House of Delegates at the One Hundred and Thirty-fifth Annual Meeting of the Medical Society of the State of New York voted unanimously "to adopt an expression of appreciation to the members and officers of the Legislature, and especially to the Governor, for the courteous reception extended to the representatives of the medical profession and the thoughtful consideration they have given medical and public health measures that have come before them."

Legislators are not mindreaders, however disposed they may be to cooperate with their constituents and with the medical profession. They are not mindreaders but lawmakers. To make laws wisely they must be accurately informed. And especially is this true concerning matters medical since such matters are frequently highly technical.

It is, therefore, up to the doctors of medicine who know about these things to keep closely in touch with their representatives not only in Albany but in Washington also. Cooperation implies equal effort on both sides. No legislator can cooperate with an indifferent, silent, or uncommunicative profession. Let every member of this Society get in contact with his representative or senator often. This is an obligation that medicine will neglect at its own peril and that constitutes a disservice to the public.

Hospital Construction Federal Bill S. 1230 (Section 45).—The House adopted a resolution which it had received from the Kings County Medical Society and revised in part to read:

"The Medical Society of the State of New York is informed that the Senate Committee on Education and Labor, of which Senator Mead is a member, has under consideration S. 1230, the Hospital Construction Bill introduced by Senator Brown of Michigan. The Society, through its proper committee, has carefully studied the bill and wishes to file with Senator Mead certain objections to it in its present form:

(1) It objects to the inclusion of an osteopath on the National Hospital Advisory Council. This designation seems unnecessary, for no hospital would be created for that form of treatment alone since it is only a specialized form of treatment.

(2) The bill seems to provide that only projects constructed within the first year shall be supervised by the advisory council. Other projects conceivably will be constructed in later years and the advisory council's authority should be extended to cover these also.

(3) The definition of the term 'hospital' in Section 18 is so worded as to permit of the construction, equipment and operation of health, diagnostic and treatment centers without specifying that there must be available bed capacity. Such centers, we believe, without available bed capacity would not constitute a hospital."

The Council directed Dr. Lawrence, the executive officer, to carry out the instruction to register the objections of the Society to the bill.

Interns—Health and Accident Insurance (Section 42).—The House received a suggestion that legislation be introduced "making it obligatory for hospitals in New York State to provide health and accident insurance for interns serving in their hospitals."

This matter was referred by the Council to its Committee on Public Relations and Economics. See Part X of the 1942 Council Report for action taken.

Invitation to American Medical Association for 1944 Meeting in New York City (Section 70).—The House authorized an invitation to the American Medical Association to hold its 1944 Meeting in New York City.

The invitation was given officially and by the delegates from the State Society. The decision of the A.M.A. House was for St. Louis in 1944.

Laboratory Medicine (Section 55).—In 1940 the House adopted the resolution:

"Be It Resolved That:

"1. The House of Delegates go on record as disapproving laboratory medicine by laymen or nonmedical personnel;

"2. That measures for establishing a proper relationship between city and state departments of health laboratories and physicians who practice pathology be endorsed;

"3. That the work of state and city departments of health be limited to the diagnosis of communicable diseases except where the diagnostic facilities of the state and city health departments are the only diagnostic means available for indigent patients."

In 1941 the House, receiving a report that conferences with representatives of various organizations on this resolution had turned up differences of opinion, adopted a recommendation "that the Council committee continue conferences looking toward the practical adoption of the spirit of the resolution by the laboratories concerned."

Formal conferences have not been held as yet.

Laboratories—Public Health (Section 55).—Recommendation: "Adoption of the principles stated in the proposal and appropriate action thereon by county medical societies and laboratory directors throughout the state." (See proposals in the *JOURNAL* for April 1, 1941.)

Formal meetings have not been held but there has been frequent informal contact with representatives of the Department of Health and of the Public Laboratories in the state, through the Council Committees on Public Health and Education and on Public Relations and Economics.

Library Fund (Section 56).—Recommendation: "the creation of a fund for a library in order to facilitate the work of the Publication Committee should be referred to the Council for study and action."

The Council delegated this study to the Publication Committee, which has not as yet made a final report.

Manhattan State Hospital—Demolition (Section 55).—The Council was charged with continuing observation of the opposed plan for early demolition of the hospital.

No action has been necessary.

Report of the Treasurer

To the House of Delegates; Gentlemen:

The financial status of the Society is shown by the following figures taken from the annual report of the auditors, Messrs. J. K. Lasser & Co., for the year 1941.

Attention might be called to a few of the items contained in it. Due to the general condition of the security market in these troubled times, there has been during the year a depreciation in the market value of our holdings of about \$8,800, but in spite of this depreciation our balance has increased by about \$14,500. This favorable financial result of a year's activities is due to our income from investments and bank balances of about \$12,300 and to the excess of dues income over operating expenses of about \$11,000.

This balance does not quite show the complete picture, however, for there are the inventories and other assets on the one side to be considered, and the liabilities on the other. The inventories and other assets total \$11,600 and the liabilities about \$8,200, so there is a favorable balance between these two items of about \$3,400. In last year's report the liabilities exceeded the inventories and other assets by \$1,400, so that in this respect we are better off than last year by about \$4,800. This should be added to

the increase in our balance, giving a figure of about \$19,300.

I wish that we could hope for a similar favorable balance next year, or even any kind of favorable balance, but the indications are all pointing in the opposite direction, with an ever increasing number of our members entering the armed services of the United States, and with the cost of materials and supplies rising sharply.

The extent to which we will suffer financially during the present fiscal year (1942 calendar year) cannot be estimated with any accuracy at the time that this report is written (March 1), but it is evident that strict economy will have to be practiced by all of us, and it is very probable that in addition some drastic curtailment of activities and services may be necessary if our expenses are to be kept from far exceeding our total income.

In closing I wish to thank those members of the office staff, who have the keeping of the books and the care of the other financial details of the Society, for the conscientiousness and accuracy with which they have performed their duties and for their cheerful cooperation.

Respectfully submitted,
KIRBY DWIGHT, M.D., *Treasurer*

March 1, 1942

Auditors' Statement

We have completed an examination of the balance sheet of the Medical Society of the State of New York as of December 31, 1941, and the statements of income and capital for the year ended with that date, and have reviewed the system of internal control and the accounting procedures of the Society, have examined or tested accounting records of the Society and other supporting evidence by method and to the extent we deemed appropriate.

In our opinion, the accompanying balance sheet and related statements of income and capital present fairly the position of the Society at December 31, 1941, and the results of its operations for the year ended that date.

Respectfully submitted,

J. K. LASSER & Co.,
Accountants & Auditors

February 2, 1942

Medical Relief (Section 72).—Resolution adopted:

"WHEREAS, the indigent of the City of New York are provided with medical care through a plan devised by the Medical and Nursing Service for Home Care; and

"WHEREAS, these same indigents require ambulatory care for which no provision is made; and

WHEREAS, the physicians of the City of New York are supplying this ambulatory care without remuneration; be it

"Resolved, that the Bronx County Medical Society recommend that provisions be made for the ambulatory care of indigent patients in the office of the private practitioners and that the physicians be adequately remunerated for this care; and be it further

"Resolved, that these resolutions be introduced at the House of Delegates at the meeting of the New York State Medical Society in April, 1941."

This matter was referred by the Council to its Subcommittee on Medical Relief.

Motor Vehicle Drivers—Medical Examinations (Section 47).—Recommendation adopted: that the following portion of the 1941 Council Report be referred back to the Council for further study and recommendation. That reads:

"Regarding drunken drivers, tests are now available to determine alcoholic content in the blood and legislation is contemplated which will permit such tests to be made where accidents have occurred. The medical profession has not as yet passed upon the proposed tests, but at least two other states have incorporated them in their restrictions."

See Part XI of Council Report for further report.

Physicians' Benevolence Fund (Section 56).—The House referred to the Council the question of creation of a Benevolence Fund for relief of physicians incapacitated by age, infirmities, and actual poverty.

The Council has received report from a committee which it appointed that in the opinion of Legal Counsel a plan originally advanced by Dr. Kosmak is legal. It is the understanding of the Council that Dr. Kosmak will present an enabling amendment to the Constitution and Bylaws.

School Health Program (Section 37).—The House adopted a recommendation:

"That the Council be instructed by this House of Delegates to continue its efforts along the present lines to the end that doctors be put in charge of health and health problems among children of school age, eventually bringing back to the Department of Health the health of our school children, because this is certainly where it belongs, and Health Education should be continued under the guidance of educators, whether lay or medical."

The Council has continued its efforts through its subcommittee. See Section III of Council Report.

Special Committees to Be Continued (Sections 39 and 56).—The House directed that the two special committees on Publication and on Office Administration and Policies be continued, to consist of the same officials: the general manager; the director of the Public Relations Bureau, who is also business manager of the *JOURNAL and Directory*; the literary editor; the treasurer; and a separate member of the Board of Trustees on each committee.

Tattoo Code for Serum Sensitive (Section 55).—Recommendation adopted:

"That the Council of this Society be instructed to draw up a resolution to be presented to the American Medical Association at its meeting in June this year, requesting the American Medical Association to appoint a committee to study this question and take suitable action thereon."

A resolution was presented to the House of Delegates of the American Medical Association on June 2, 1941, where the matter was referred to the Council on Scientific Assembly for study and such action as its Board of Trustees might order.

Thoracic Diseases—Symposium (Section 44).—The House, receiving a request for creation of a new "Session on Thoracic Diseases," requested instead that the Council "consider the incorporation of a symposium on thoracic diseases."

The Council approved a decision by its Subcommittee on Scientific Program of its new Committee on Convention to devote one of the two general sessions at the 1942 Meeting to thoracic diseases.

Women Physicians for Army and Navy Medical Corps (Section 69).—The House instructed the Delegates of the State Society to introduce a resolution in the meeting of the American Medical Association House of Delegates, favoring admission of women physicians to the Medical Corps of the Army and Navy.

This instruction was carried out on June 2, 1941. The resolution was defeated.

Workmen's Compensation (Section 58).—The House adopted recommendations:

1. For modification of Section 13-g(2) to remove necessity of the Medical Society arbitrating hospital bills.
2. Revision of Statute Subsection 13-g to include a sentence to enforce payment of "bills not objected to" without necessity of court action.
3. Amendment to Section 13-g(2) so that disputes in regard to the payment of a bill because of alleged failure of a physician to obtain authorization should be arbitrated.

The suggested amendments were referred to the Legislative Committee by the Council.

The House referred to the Council for further consideration the question of placing the director of the Workmen's Compensation Bureau on a full-time instead of part-time basis.

The Council after study decided not to change the basis of employment of the director.

volve expenditure of money to plan seriously on the cutting down of their outlays and the making of substantial budgetary savings."

The Board is glad to report that the financial condition of the Society continues sound and that so far the Society has lived within its income from dues without embarrassing curtailment of its activities or the shirking of any of its truly important duties and responsibilities. Serious concern for the future along financial as

well as other lines, however, is distinctly in order.

Report of the Counsel

To the House of Delegates; Gentlemen:

Your Counsel herewith submits his report of the activities of the Legal Department of the Medical Society of the State of New York for the period from February 1, 1941, to and including January 31, 1942.

Brevity is the objective to be sought in the making of a report of this character. Thus, only the barest outline of the work done in our Department can be given. This, of course, does not give any adequate picture of the work done or the responsibility assumed by our Department.

At the outset of this report, we wish to record our grateful appreciation for the assistance and cooperation furnished by your officers and your committeemen.

In making his report, your Counsel adheres to the convenient category employed in previous years whereby his activities have been divided into three main divisions: (a) the actual handling of malpractice actions before courts and juries and in the appellate tribunals; (b) counsel work with officers, committees, and individual members of the Society; and (c) legislative advice and activities.

Litigation.—For a number of years we have called to the attention of the membership the dangers of careless, hasty, and unjustified criticism by one physician of the work of another. We feel it necessary to do so again this year. In these times of unrest and economic distress not much is needed to plant in the mind of a patient the idea of a malpractice action. While the matter is not susceptible of definite proof, we feel that we state a fact when we say that many malpractice actions stem from just such criticism. The fact that the physician does not, in many instances, intend that his remarks shall result in a malpractice action, does not help the situation. When the criticism is made, the damage has been done.

It is almost unnecessary to call to the attention of your membership the ever present hazard of a malpractice action to the practicing physician, nor should it be necessary to note that the rights of the physicians in malpractice actions are in the hands of lay jurors, who frequently are unduly influenced by factors that do not go to the merits of the case. While theoretically sympathy, passion, prejudice or bias have no place in the jury box, as a practical proposition we know that jurors are rendering verdicts every day in our courts where these elements or some of them are responsible for the verdict.

It is difficult to understand why more of the members of your Society do not avail themselves of the Group Plan of insurance sponsored

by the State Society. We have yet to meet a physician facing a lawsuit without this insurance who did not voice deep regret over his failure to take advantage of the benefits of the Group Plan. The Group Plan deserves and should receive the loyal support of every member of the Society. It has been in operation for some twenty years and its outstanding success is a matter of record.

At this point mention should be made of the Yorkshire Indemnity Company, the carrier under your Group Plan. This company is now entering its seventh year as such carrier. It has lived up in every way to all of its obligations and, in addition, has demonstrated its genuine and enthusiastic interest in the successful operation of our Group Plan. Appreciation should be recorded of the cooperation furnished by Mr. Horace Crowell, Jr., claim agent of the Yorkshire Indemnity Company, with whom your Counsel and office staff are in almost daily conference and consultation.

Mention should also be made of the splendid work of your Insurance Committee headed by Dr. Clarence G. Bandler. We have conferred on a number of occasions during the reporting period with Dr. Bandler with relation to the problems before the Insurance Committee.

We also have conferred with Mr. Harry F. Wanvig, the authorized insurance indemnity representative, and with his office staff on various matters pertaining to the operation of the Group Plan.

For many years I have recorded in this report my deep appreciation for the splendid work of my associates, Mr. William F. Martin and Mr. Thomas H. Clearwater.

Mr. Martin's reputation in the defense of malpractice actions is well and favorably known throughout the entire state. His experiences in this field for fourteen years have won for him expressions of the highest approval from judges, lawyers, and doctors in all parts of the state, not only for his exceptional ability as an advocate but for his fine personal qualities as well.

Mr. Thomas H. Clearwater, the Attorney for your Society, has had close contact for many years with the members of your Society and with its officers and committeemen. Mr. Clearwater is a gentleman of exceptional ability and character, and he has rendered to your Counsel at all times the fullest measure of cooperation and support.

We cannot leave this subject without paying tribute to the splendid spirit of industry, loyalty, and devotion manifested by your Counsel's entire staff, both legal and clerical.

With this preliminary statement, we note

Report of the Board of Trustees

To the House of Delegates; Gentlemen:

I have the honor to report for the Board of Trustees on its supervision of the financial affairs of the Society since your last meeting on April 29, 1941.

At that meeting there were passed amendments to the bylaws of the Society changing the fiscal year to coincide with the calendar year. It became necessary, therefore, first, that the Council present, and the Board of Trustees approve, a budget for the six months from July 1, 1941, to December 31, 1941. This was done, and then later a budget for the full year 1942 was set up and approved in similar fashion.

Contract renewals were made with the Executive Officer and with Mr. Kent Lighty for securing advertisements for the *JOURNAL and Directory* and for sale of technical exhibit space for the 1942 Annual Meeting. Re-employment of Mr. Brosnan as legal counsel, Mr. Clearwater as attorney, and Dr. Kaliski as director of the Bureau of Workmen's Compensation was effected.

On recommendation of the Council that Dr. Irving and Dr. Lawrence attend the meetings of the House of Delegates of the American Medical Association, the Board authorized payment of travel expenses on the same basis as for the elected delegates.

The investments of the Society have been the subject of close and constant study, in the double effort to maintain income from securities and at the same time to keep the funds invested as

sound as possible in these times. Upon advice of the Chase National Bank, some securities have been sold and others purchased.

In view of the policy adopted of remitting state assessments for members who went into military or naval service before June 1, 1941—and a considerable increase is expected before June, 1942—the Board has counseled all officers and chairmen of committees to pay particular attention to the limitation of expenditures. The following letter, signed by the chairman at the instance of the Board, was sent to those concerned, on January 17, 1942.

"At its meeting on January 8, 1942, the Board of Trustees requested me as its chairman to transmit to the administrative officers of the Society and the chairmen of all Council Committees a memorial urging them to conserve their Society resources by limiting their expenditures.

"This decision was reached after the Board had considered probable diminution in income that would develop from increased remissions of state assessments because of active military and naval service. In addition, the Board felt that rising taxes and interference with ordinary business might so disturb the financial status of other members that they might be unable to pay their dues. It seems the part of wisdom, therefore, for all concerned with the various Society activities that in-

physician who, upon entering the military service, turns over his practice to another physician on a percentage basis.

21. Inquiry concerning the legal consequences of a verbal consent to operation as distinguished from a written consent.

Other Counsel Activities.—Your Counsel, acting with the Committee on Bylaws, examined various proposed amendments to the Constitution and Bylaws of a number of component county societies and has rendered advice and made suggestions in connection therewith.

Your Counsel drew the contracts between Mr. Kent Lighty and the State Society with reference

to advertising matter in the NEW YORK STATE JOURNAL OF MEDICINE, the *Medical Directory of New York, New Jersey, and Connecticut*, and the Commercial Exhibits.

Your Counsel drew the contract between the Society and Dr. Joseph S. Lawrence, its executive officer.

Your Counsel drew the contract between the Society and Dr. Peter Irving, its secretary and general manager.

Your Counsel also drew the contract between the Society and Mr. Dwight Anderson, as director of the Public Relations Bureau and business manager of the NEW YORK STATE JOURNAL OF MEDICINE and the *Medical Directory of New York, New Jersey, and Connecticut*.

Your Counsel has conferred at various times with members of the various committees on certain phases of their work.

Your Counsel attends and advises at the monthly meetings of the Council of your Society.

Your Counsel is constantly in communication by telephone and letter with Dr. Peter Irving, secretary and general manager of the Medical Society of the State of New York, with regard to the many questions which arise almost daily in connection with his work.

It should also be noted that daily telephone calls from members of the Society come to your Counsel and his office staff, which require advice and assistance on various problems. Most of these telephone inquiries present emergency situations which cannot be handled by correspondence.

Legislative Advice and Activities.—During the period of time that the Legislature was in session in 1941, your Counsel examined certain bills affecting the medical profession and gave advice with respect thereto, and conferred with the Executive Officer of the Society regarding such bills on various occasions.

Mr. Clearwater attended the Annual Conference of the Council Committee on Legislation with the Chairmen of the County Society Legislation Committees held at Albany.

At the time of the writing of this report, your Counsel has already been in conference with the Executive Officer and numerous other persons with respect to certain bills before the Legislature at its current session. Of particular importance among said bills presently before the Legislature is that designed to modify the Statute of Limitations on malpractice actions, which bill your Counsel has been and is continuing to oppose vigorously.

At present, the Statute of Limitations applicable to malpractice actions provides that such cases must be instituted within two years after their accrual. By said bill, it is proposed to change the law so that such actions must be commenced within one year after their accrual with the proviso that they are not deemed to have accrued until discovery of malpractice by the patient and with the further proviso that in no event shall they be brought more than six years after the treatment of the case.

Upon cursory analysis, the bill would seem to have some merit, but it is your Counsel's opinion that possible advantages of the proposed legislation would be far outweighed by the fact that physicians would be subjected to numerous actions instituted as much as six years

that there were commenced within the present reporting period 153 cases. These figures, of course, do not include a number of claims outstanding on which suit may ultimately be brought. Of equal importance with the actual work of litigation is the preventative work done by your Counsel and his office staff. Throughout the year we are in consultation with many claimants and their attorneys and frequently we have been successful in demonstrating to them in fact and in law that no valid claim exists. Thus these claims never reach a suit stage.

Table 1 shows that during the present reporting period we disposed of 146 cases. Fifty-two of these cases were settled and 89 terminated successfully in favor of the physician. In 5 cases there were judgments for the plaintiff.

We note from Table 1 that there were pending as of January 31, 1942, 413 cases.

Table 2 gives the number of members insured during the reporting period, the number of members in the county societies, and the percentage of insured members.

Counsel Work.—During the period of this report, your Counsel prepared for the Society's JOURNAL articles in the nature of editorial comment. These articles have included the following: Responsibility of Physician for Acts of Nurse; Responsibility of Surgeon for Care Following Operation; Physicians and Surgeons—Evidence of Malpractice; Liability of Surgeon in Needle Breaking Case; Workmen's Compensation—Alleged Fraud in Physician's Report; Licensing of Foreign Physicians; Privilege—Public Health Records; Wrongful Death Case—Failure of Proof.

At the request of the House of Delegates, your Counsel has also prepared for publication in the JOURNAL a number of inquiries and the answers to the same which have been received from members of the Society seeking information on legal questions considered to be of general interest to the profession.

In addition, your Counsel has prepared for publication in the JOURNAL several digested reports of cases handled by your Counsel which were considered to be of interest to the members of the profession.

Your Counsel is pleased to learn from the members of your Society, from time to time, that they enjoy reading these reports and articles and that they find them to be interesting and instructive.

In addition to his other duties, your Counsel receives frequent requests for opinions, orally and in writing, on various topics. Some of the matters upon which advice has been given (in writing) are the following:

Inquiries.—1. Inquiry from a physician as to the propriety of revealing confidential and professional information obtained in examining applicants for factory employment.

2. Inquiry regarding the legality of use of nonhusband donor for artificial insemination.

3. Several requests for information regarding the recent amendments to the Education Law relating to interns and residents.

4. Request for an opinion concerning the extent to which an intern, resident, or medical student may legally practice medicine.

5. Inquiry as to the liability of a hospital

Board of Managers for the acts of doctors, interns, nurses, or others associated with the hospital.

6. Request for information as to whether resident physicians must be licensed.

7. Inquiry as to the legality of an arrangement whereby a practicing physician has associated with him a nonlicensed physician.

8. Request for information as to the method of incorporating a Medical Society.

9. Inquiry concerning remuneration for the care of relief cases.

10. Inquiry with respect to the necessity for written consent to operations.

11. Inquiry as to the right to collect a fee when a substitute attends a patient during delivery.

12. Request for advice as to whether a practitioner licensed in New York is entitled to practice medicine in Massachusetts.

13. Inquiry as to the responsibility of a physician for the acts of a doctor taking over his practice when the former enters the military service.

14. Request for an opinion from a physician as to his right to reveal confidential information (a) to another physician and (b) to an insurance company.

15. Requests for forms of consent to operation.

16. Inquiry as to the right to perform a postmortem cesarean without permission.

17. Inquiry as to the right to perform sterilization operations where no medical reason exists.

18. Inquiry as to the right of a physician to utilize the services of a nonnurse assistant in the administration of diathermy treatment.

19. Inquiry as to the necessity of operative consent in cases involving minors.

20. Inquiry as to the legal responsibility of a

Telegraph Company, New York City; Occupational Diseases, Dr. Irving Gray, chairman, Committee on Industrial Health, Medical Society of the County of Kings, slide demonstration; The Prevention of Infection in Injury, Dr. Samuel Potter Bartley, chief, Traumatic Clinic, Long Island College Hospital, Brooklyn; Placement of the Handicapped, Murray Nathan, member of administrative staff, New York State Employment Service, Albany; Rehabilitation, Dr. Henry H. Kessler, medical director, New Jersey State Rehabilitation Clinic, Newark, New Jersey. A sound film was shown.

At the afternoon session we were especially honored in having as our guest speaker Dr. Frank H. Lahey, director of the Lahey Clinic in Boston and president of the American Medical Association. Dr. Lahey talked on Diseases of the Thyroid Gland. An exceptionally fine slide demonstration accompanied the address.

Between the morning and afternoon sessions, a luncheon was held at the hotel attended by 188 physicians and members of the woman's auxiliaries of the four component county societies of the Second District Branch.

We were addressed after the luncheon by Dr. Samuel J. Kopetzky, president of the Medical Society of the State of New York. Dr. Frank Lahey also spoke at this time.

At the morning meeting the auxiliaries heard Dr. Luvia M. Willard, president of the American Women's Hospital Reserve Corps. Dr. Kopetzky, president, and Dr. Joseph Lawrence, executive officer of the State Society, talked to the auxiliaries in the afternoon.

In addition to Dr. Kopetzky and Dr. Lawrence, other State Society officials present at our meeting were Dr. Peter Irving, secretary and general manager; Dr. Louis H. Bauer, speaker of the House of Delegates; Dr. William H. Ross, trustee; Drs. Herbert H. Bauckus and Augustus J. Hambrook of the Council; and Mr. Dwight Anderson, director, Public Relations Bureau.

During this year I have visited the four component county societies in the Second District Branch.

Respectfully submitted,

BURDGE P. MACLEAN, M.D., President
February 13, 1942

Report of the Third District Branch

To the House of Delegates; Gentlemen:

A successful meeting of the Third District Branch was held at Catskill on September 30, 1941, at which time an unusual and unique program was presented.

Approximately seventy-five doctors attended the meeting, with a good representation of each county society of the Branch. The morning session was given up to the chairmen of the standing committees of the Medical Society of the State of New York, each giving a résumé of his own work and problems.

An excellent luncheon was served at noon, and Dr. Samuel J. Kopetzky, New York City, president of the State Society, was the speaker. In the afternoon the chairmen of the Council committees of the State Society met at a round-table discussion with the chairmen of the corresponding standing committees of each county

society. Branch. and educational, and I feel that each doctor went back to his own county medical society with a message of inestimable value concerning the workings of the State Medical Society.

I believe this type of meeting should be rotated around the various district branches at least once a year, for what our Branch learned at this meeting gave us an entirely different slant on the general workings of the State Medical Society.

Respectfully submitted,

MAHLON H. ATKINSON, M.D., President

March 10, 1942

Report of the Fourth District Branch

To the House of Delegates; Gentlemen:

The thirty-fifth annual meeting of the Fourth District Branch was held on Friday and Saturday, September 26 and 27, 1941, at the Lake Placid Club. The Essex County Society was the host Society.

The meeting was called to order at 2:00 P.M., daylight-saving time, and the first order of business was the presentation of a memorial in honor of our president, Dr. E. Harrison Ormsby, who had died on July 18, 1941. This memorial was written by a committee of Dr. H. S. Howard, of Minerville, and Dr. C. K. Tomlinson, of Amsterdam. It was presented by Dr. Stephen H. Curtis, of Troy. A motion was passed that this memorial be spread upon the minutes of the District and that a copy be sent to Dr. Ormsby's family.

The scientific program was devoted to a Symposium on Tuberculosis. There were four papers: The first was on "Tuberculosis Control and Case Finding in a Rural Community" by Dr. Richard Nauen of the New York State Hospital for Incipient Tuberculosis at Ray Brook. Dr. Beverly L. Vosburgh, of Schenectady, spoke on "Tuberculosis in Industry," and Dr. Fred H. Heise, medical director of Trudeau Sanatorium, spoke on the "Management of Pulmonary Tuberculosis." Dr. Warriner Woodruff, of Saranac Lake, discussed the "Role of Surgery in Pulmonary Tuberculosis."

While the afternoon session was in progress, the Women's Auxiliary of the Essex County Medical Society sponsored a trip up Whiteface Mountain for the visiting ladies.

The annual dinner was held that evening in the dining room of the Lake Placid Club. Dr. Samuel J. Kopetzky, president of the Medical Society of the State of New York, addressed the Society with particular reference to our part in the war. Following this, Dr. F. Leslie Sullivan, of Scotia, introduced Mr. James Stewart, who gave an interesting account of his experiences on the ship *Zanzam* when it was captured and sunk by a German raider, and his further experiences in concentration camps and his escape. During the banquet, music was furnished by the Lake Placid Club Orchestra.

The Saturday meeting was called to order at 10:00 A.M. and the morning was devoted to a Symposium on War Surgery. Dr. John Scudder, of New York City, was the first speaker, his topic being "Blood Studies in Shock as a Guide

after treatment, in which fraudulent claims of delayed discovery of malpractice would be made the basis of evading the Statute of Limitations. Instead of cutting the statutory period from two years to one year, the practical effect of the bill would be to extend that period from two years to six years.

Conclusion.—In closing this report your Counsel wishes to record his appreciation for the work of his office staff, and also to note with grateful thanks the advice and assistance of the members

of your Society who have helped us both in court and by consultation in the defense of malpractice actions.

Without the cooperation and assistance of all concerned, it would not be possible for your Counsel to have obtained the results shown in this report.

Respectfully submitted,

LORENZ J. BROSNAN, *Counsel*

January 31, 1942

Amendments to Constitution and Bylaws

To the House of Delegates; Gentlemen:

At your last meeting notice was given of two amendments to the Constitution which will come before you for action at your coming meeting on April 27, and which in accord with our Constitution are published in advance of that meeting. This will not go before a reference committee, but to you as a whole. Under our present Constitution, "a two-thirds vote of the members of the House of Delegates present and voting shall be necessary for adoption."

The first is a proposed amendment to Article IV of the Constitution, which reads:

"There shall be a Council composed of the president, the president-elect, the immediate past-president, the secretary, the treasurer, the speaker, and nine other members elected by the House of Delegates."

The proposed amendment is to insert after the word "speaker" the words "chairman of the Board of Trustees" so that as amended it will read:

"Article IV—Council"

"There shall be a Council composed of the president, the president-elect, the immediate past-president, the secretary, the treasurer, the speaker, the chairman of the Board of Trustees, and nine other members elected by the House of Delegates."

The second amendment proposed is to Chapter 7 of the Bylaws, to be Section 13 as follows:

"Any officer of the Medical Society of the State of New York or its district branches, who is called into active service with the armed forces of the United States, may, upon application to the Council, be granted leave of absence for any portion of his term of office during which he is on active service. During such absence, his duties shall be delegated as the Council may direct except where such delegation is already provided for elsewhere in the Bylaws."

Respectfully submitted,

LOUIS H. BAUER, M.D., *Speaker*

March 9, 1942 PETER IRVING, M.D., *Secretary*

Report of the First District Branch

To the House of Delegates; Gentlemen:

The annual meeting of the First District Branch was held at the Mount Sinai Hospital, New York City, on October 8, 1941.

The meeting, extending from 9:00 A.M. to 5:00 P.M., followed the general pattern of the previous few years and served as a "one-day postgraduate course." The attendance reached an all-time high, and during the day there were almost six hundred registrants.

Arranged by the Hospital Committee on Medical Instruction under the able chairmanship of Dr. Reuben Ottenberg, over one hundred members of the staff collaborated to cover every branch of medicine and surgery except obstetrics and contagion. Lectures; clinics, both dry and operative; ward rounds; exhibits; demonstrations and motion pictures; all were skillfully integrated to produce a complete "refresher session" and to present "What Is New."

To Dr. Ottenberg and his associates is extended full credit for the excellent arrangement and faultless execution of an elaborate program.

Through its director, Dr. Joseph Turner, appreciation is extended to the hospital for an excellent luncheon.

At luncheon, in the unavoidable absence of Dr. Samuel J. Kopetzky, president of the State Society, Dr. William A. Krieger, the vice-president, briefly addressed the meeting. His remarks were timely and well received.

Respectfully submitted,

ALEXANDER N. SELMAN, M.D., *President*

February 12, 1942

Report of the Second District Branch

To the House of Delegates; Gentlemen:

The annual meeting of the Second District Branch was held at the Garden City Hotel, Garden City, on October 30, 1941.

Exhibits of a unified County Cancer Program were furnished through the Nassau County Cancer Committee, Meadowbrook Hospital, and New York Memorial Hospital. The exhibits on industrial accidents and industrial diseases were furnished by the New York State Department of Labor.

The morning session was devoted to a Symposium on Industrial Medicine and was ably covered by the following programs: Pre-Placement Examination, Dr. Cassius H. Watson, medical director, American Telephone and

Report of the Seventh District Branch

To the House of Delegates; Gentlemen:

The annual meeting of the Seventh District Branch was held on Thursday, September 25, 1941, at the Oak Hill Country Club, Rochester.

The meeting was called to order at 9:45 A.M., and the following program was carried out:

Four motion sound pictures were shown: "More Trifles of Importance," "XXX Medico," "The Hidden Master," and "A Way in the Wilderness." Under the direction of Dr. George Hoyt Whipple, dean and professor of pathology, University of Rochester School of Medicine, a group discussion was held on "Plasma Proteins and Clinical Problems." A paper was read by Dr. Walter E. Dandy, Johns Hopkins University School of Medicine, Baltimore, on "The Diagnosis and Treatment of Lesions of the Cranial Nerves," with discussion by Drs. William P. Van Wagenen and Henry W. Williams, both of Rochester. At luncheon Dr. Samuel J. Kopetzky, president of the Medical Society of the State of New York, was introduced and spoke on "Medical Preparedness."

The entire afternoon session was devoted to a forum on medicine and surgery: "Health and Disease in Infancy and Childhood," conductor, Dr. Albert D. Kaiser; "Modern Drug Therapy," conductor, Dr. James H. Sterner; "The Gastrointestinal Tract from Medical and Surgical Points of View," conductor, Dr. W. J. Merle Scott; "The Puerperal Period and Its Complications," conductor, Dr. James K. Quigley.

The following officers were elected at the business meeting: president, Dr. Benjamin J. Slater, Rochester; 1st vice-president, Dr. Homer J. Knickerbocker, Geneva; 2nd vice-president, Dr. Howard S. Brasted, Hornell; secretary, Dr. L. F. Allen, Pittsford; treasurer, Dr. Kenneth T. Rowe, Dansville.

The attendance at the meeting was excellent, there being more than three hundred doctors present from the District.

I wish to express my gratitude for the splendid cooperation I received from the local committee of the Branch in Rochester, who so ably assisted me and the officers in the preparation of the program and in carrying out the necessary arrangements for the meeting.

Respectfully submitted,

FREDERICK W. LESTER, M.D., President
February 10, 1942

Report of the Eighth District Branch

To the House of Delegates; Gentlemen:

The thirty-sixth annual meeting of the Eighth District Branch of the Medical Society of the State of New York was held at Jamestown, October 2, 1941. The program presented was most interesting and was very well attended.

Motion pictures entitled "Appendicitis," by Dr. Joseph Brenemann, Chicago, emeritus professor of pediatrics at Rush Medical School, and "Pneumonia," by Dr. Isaac Arthur Abt, Chicago, professor of pediatrics at Northwestern Medical School, opened the program at 9:30 A.M.

Following these, the first of the scientific papers was given by Dr. Herman E. Pearse,

assistant professor of surgery, University of Rochester School of Medicine, on "Injection Treatment of Varicose Veins." Dr. Pearse described first the methods used by Celsus in the first century and then the various methods in use today, along with the indications and contraindications. He also described the necessary tests to be carried out before such therapy is instituted. The various solutions used in this work were described, and their relative efficiency was discussed; also the treatment of varicose ulcers was briefly outlined.

Following this paper, Dr. J. Harold Couch, F.R.C.S., Department of Surgery, University of Toronto, discussed the practical subject, "Amputations Through the Hand." He emphasized the importance of a good functional result, especially in industrial compensation cases where the worker must earn his livelihood despite his physical handicap. Dr. Couch accompanied his talk with colored movies to illustrate graphically his subject, patients from all walks of life being presented.

Therapeutics, especially if devoted to the ever widening field of chemotherapy, play an essential part in the practice of modern-day medicine and surgery. Dr. W. Barry Wood, Jr., associate in the Department of Medicine, and associate physician to the Johns Hopkins Hospital, gave an interesting paper on "The Clinical Use of the Sulfonamide Group of Drugs." Dr. Wood spoke briefly of the problems encountered in the vast amount of research work done with the "sulfa" group of drugs from the time they were first used eight years ago in Germany until the present. He presented the various drugs: sulfanilamide, sulfapyridine, sulfathiazole, sulfaguanidine, and the newest one in common use—sulfadiazine; he also discussed the various diseases and conditions for which each drug might be most effectively used.

Following his paper, luncheon was served the members of the society and their wives. At this time Dr. Samuel J. Kopetzky, president of the State Society, outlined the role that medicine is being called upon to play in the civilian defense program of this country. He also asked for the cooperation of the medical profession in carrying through the rehabilitation program for those draftees rejected for army service because of physical defects which might easily be corrected.

At the conclusion of the luncheon, the business meeting was held, and the following officers were elected for the ensuing two years: president, Dr. Robert C. Peale, Olean; first vice-president, Dr. Peter J. Di Natale, Batavia; second vice-president, Dr. John C. Kinzly, North Tonawanda; secretary, Dr. Hall G. VanVlack, Jamestown; treasurer, Dr. William J. Orr, Buffalo.

The afternoon program began with a "Critical Review of Procedures of Active and Passive Immunization" by Dr. John A. Toomey, Cleveland, Ohio, chairman, National Committee of Immunization Procedures, professor of pediatrics, Western Reserve Medical School. The speaker considered practically all the contagious diseases individually and outlined the most efficient methods of immunization against each. He also commented on the value, as well as the dearth of value, of many of the immunization procedures and products in common use. As

to Therapy." This was a very interesting paper and was accompanied by movies. Lieutenant Colonel George A. Koenig spoke on "War Wounds of the Extremities with and without Involvement of the Bony Structures." This brought out the recent advances in traumatic surgery. The third paper was by Dr. John M. Converse on the "Problem of Burns in Warfare." Dr. Converse had just returned from England and presented a résumé, accompanied by pictures, of the latest advances in the treatment of burns.

At the conclusion of the morning program most of the members and their ladies took a boat trip up Lake Placid to Moose Island where a picnic lunch was served. Both the boat ride and the picnic were enjoyed by those present.

Registration for this meeting was seventy-two, of which fifty-six were from the District. This was less than 9 per cent of the District membership. Fifty per cent of the members of the Essex County Society were present, but there were very few present from some of the more distant counties, an exception being Schenectady County which had ten representatives, or an average of 7 per cent.

Respectfully submitted,

WARRINER WOODRUFF, M.D., *Acting President*
March 9, 1942

Report of the Fifth District Branch

To the House of Delegates; Gentlemen:

The thirty-fourth annual meeting of the Fifth District Branch was held Tuesday, September 23, 1941, in the Hotel Syracuse at Syracuse, there being about one hundred members of the District present.

The program, which was well diversified, was opened at 9:30 A.M. by a motion picture made by Drs. H. Dan Vickers and Joseph W. Conrad, Little Falls, showing the technic of the "Use of Wire Sutures in Surgery." This picture showed some of the work done in the Little Falls Hospital in the past three years.

A well-prepared paper on kidney infection was read by Dr. Leo E. Gibson, Syracuse. It was entitled "Blood Stream Infection of the Cortex of the Kidney" and was illustrated by slides.

Dr. Walter S. McClellan, medical director of the Saratoga Spa, presented a paper entitled "Facilities, Personnel, and Waters as Presented for Treatment at the Saratoga Spa."

Dr. William H. Wehr, surgeon, State Institute for the Study of Malignant Disease, presented an up-to-date résumé of the various types of cancer, with some newer ideas as to therapy.

At the luncheon attended by the physicians and their wives, many officers and guests were presented. The ladies of the Onondaga County Medical Auxillary presented a well-acted comedy on the life of a public clinic physician. This was well received by all. Dr. Kopetzky, State Society president, gave a thoughtful talk in the trends of medicine and also presented much on what was to be expected from the profession by the military of the country.

The afternoon session was opened with an illustrated paper on "Blood Studies in Shock as a Guide to Therapy" by Dr. John Scudder, New York City. This was a well-presented scientific paper and evoked much discussion.

Dr. Howard K. Thompson, Boston, presented a paper on "Chronic Arthritis from the Standpoint of the Practicing Physician," giving a review of the newer and older forms of therapy in arthritis.

Dr. Charles Bove, New York City, gave an interesting paper on "The Modern Care of Civilian and Military Casualties Under Warfare." Dr. Bove was in France during the siege of Paris; he talked of his experience in caring for war casualties and told of the types of injuries and burns encountered.

At the business session the following officers were elected: president, Dr. Edward C. Reifenstein, Syracuse; first vice-president, Dr. William Hale, Utica; second vice-president, Dr. Sherman M. Burns, Oswego; secretary, Dr. H. Dan Vickers, Little Falls; treasurer, Dr. Edgar O. Boggs, Lowville.

Respectfully submitted,

FRED C. SABIN, M.D., *President*

March 1, 1942

Report of the Sixth District Branch

To the House of Delegates; Gentlemen:

The thirty-fifth annual meeting of the Sixth District Branch of the Medical Society of the State of New York was held at the Mary Imogene Bassett Hospital, Cooperstown, on Thursday, September 18, 1941. Eighty-seven registered for the meeting.

In addition to the papers on the scientific program, the luncheon meeting at the Cooper Inn was addressed by Col. Samuel J. Kopetzky, president of the Medical Society of the State of New York, who spoke on "Medical Problems in the Defense Program." The program was as follows:

Morning Session.—"The Medical Examiner and the Coroner—Is New Legislation Needed?" Dr. Gilbert Dalldorf, director of the Division of Laboratories, Grasslands Hospital, Valhalla; "Diagnosis and Rationale in Treatment of Carcinoma of the Breast," Dr. Hugh Auchincloss, professor of clinical surgery, College of Physicians and Surgeons, Columbia University; "Involuntary Melancholia," Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania School of Medicine.

Afternoon Session.—"Management of the Patient with Cardiac Pain," Dr. Robert L. Levy, professor of clinical medicine, College of Physicians and Surgeons, Columbia University; "The Physiology of High Altitude Flying" (motion pictures), Dr. Walter M. Boothby, professor of experimental metabolism, The Mayo Foundation, and director of the Laboratory for Research in Aviation Medicine; "Clinical Applications of Recent Advances in Nutrition," Dr. Norman H. Jolliffe, associate professor of medicine, New York University College of Medicine.

Among the scientific exhibits was one from Cornell University showing the results of researches in nutrition and in the properties of radioactive phosphorus; another dealt with tumors of the brain and prognosis in tuberculosis.

Respectfully submitted,

G. M. MACKENZIE, M.D., *President*

February 6, 1942

1942 Annual Meeting

Medical Society of the State of New York

April 27, 28, 29, 30—The Waldorf-Astoria, New York City

House of Delegates

The regular Annual Meeting of the House of Delegates of the Medical Society of the State of New York will be called to order at 10:00 A.M. on Monday, April 27, in the Ballroom of the Waldorf-Astoria.

In accordance with Chapter II, Section 3, of the Bylaws, the House will assemble according to the following schedule:

MONDAY, APRIL 27, 1942

10:00 A.M. and 3:00 P.M.

TUESDAY, APRIL 28, 1942

9:00 A.M. and 1:00 P.M.

At the last adjourned session (1:00 P.M., Tuesday), the election of officers, counselors, trustees, and delegates will occur in accordance with Chapter III, Section I of the revised By-laws.

LOUIS H. BAUER, M.D., *Speaker*
PETER IRVING, M.D., *Secretary*

Annual Meeting

The Annual Meeting of the Medical Society of the State of New York will be held on Tuesday, April 28, at 7:00 P.M., in the Ballroom.

SAMUEL J. KOPETZKY, M.D., *President*
PETER IRVING, M.D., *Secretary*

Registration

Registration will be held in the hotel—for delegates on Monday, April 27, after 9:00 A.M.; for members on Monday, Tuesday, Wednesday, and Thursday, April 27, 28, 29, 30, from 9:00 A.M. to 6:00 P.M.

Exhibits

Scientific and Technical exhibits will be located in the hotel.

Scientific Motion Pictures will be shown.

Scientific Sessions

General Sessions on Tuesday and Thursday afternoons. Section and Session meetings will be held on Tuesday morning, Wednesday morning and afternoon, and Thursday morning.

136th Annual Meeting

The Waldorf-Astoria, Ballroom, Tuesday, April 27, 7:00 P.M.

Calling the Society to order by the President, Samuel J. Kopetzky, M.D.

Reading of the minutes of the 135th Annual Meeting by the Secretary, Peter Irving, M.D.

The Annual Banquet

The Annual Banquet will be held in the Ballroom on Tuesday, April 28, at 7:00 P.M., guest speakers to be announced.

Requests for tickets and reservations should be sent to Alfred M. Hellman, M.D., *chairman*, Banquet Committee, % Medical Society of the State of New York, 292 Madison Avenue, New York City, or telephone Murray Hill 3-9841. Tickets: \$5.00.

The Woman's Auxiliary

See page 722 for the program.

an example of the latter, Dr. Toomey stated that at the present time there are no vaccines effective against poliomyelitis.

The last paper, "Pathology of Uterine Cervix as Encountered in General Practice," was presented by Dr. James E. King, gynecologist-in-chief, Buffalo General Hospital, professor of gynecology, University of Buffalo School of Medicine. Dr. King outlined many of the conditions commonly present in the pelvis that may

be successfully treated by the general practitioner.

The entire meeting was well attended, there being almost three hundred present, including the physicians' wives, for the scientific program and the luncheon. The ladies were conducted on an interesting trip through the Furniture Exposition Building after the luncheon.

Respectfully submitted,

JOHN C. KINZLY, M.D., *Secretary*

October 10, 1941

SECTIONS

All papers read before the Society by members become the property of the Society. The original copy of each paper shall be left with the secretary of the section.

Discussers should have their remarks typed, double-spaced, and hand them to the secretary.

Time limits: Twenty minutes for each paper, five minutes for individual discussion.

Section meetings will begin promptly at the hour specified.

SECTION ON
ANESTHESIOLOGY

Chairman...Harold C. Kelley, M.D., New York
Vice-Chairman.....
.....Clifford E. McElwain, M.D., Syracuse
Secretary...Milton C. Peterson, M.D. New York

Tuesday, April 28—10:00 A.M.

The Waldorf-Astoria, 4-U Blue Room

1. "Some Pertinent Observations on Anesthesia in Relation to Neurosurgery"
Bert B. Hershenson, M.D., Brooklyn
Discussion: Leo M. Davidoff, M.D., Brooklyn
2. "The Absorption of Carbon Dioxide in Anesthesia Apparatus"
Douglass H. Batten, M.D., Brooklyn
Discussion: Melville G. Kilborn, M.D., West Orange, New Jersey (By invitation)
3. "Respiratory Derangements During Anesthesia"
Charles L. Burstein, M.D., New York
Discussion: McKinnie L. Phelps, M.D., New York
4. "Movements of Body Water in Relation to Anesthesia"
Henry G. Barbour, M.D., New Haven, Connecticut (By invitation)
Discussion: Magnus I. Gregersen, Ph.D., New York (By invitation)

Wednesday, April 29—2:00 P.M.

The Waldorf-Astoria, 4-U Blue Room

1. "The Accumulation and Dissemination of Knowledge in Anesthesiology"
E. A. Rovenstine, M.D., New York

ROUND-TABLE DISCUSSION
ANESTHESIOLOGY

- "A. Inhalation Anesthesia; B. Regional and Spinal Anesthesia; C. Intravenous Anesthesia; D. Resuscitation"
- Frederick A. D. Alexander, M.D., Albany
E. Joseph Delmonico, M.D., Syracuse
Milton C. Peterson, M.D., New York
E. A. Rovenstine, M.D., New York
Paul M. Wood, M.D., New York

SECTION ON
DERMATOLOGY AND SYPHILOLOGY

Chairman.....
.....George Clinton Andrews, M.D., New York
Secretary.....
.....Richard LeRoy Saunders, M.D., Buffalo

Industrial Dermatoses

Attention of members of the section is called to the meeting Wednesday morning, April 29, in the Lounge Restaurant of the Section on Industrial Medicine and Surgery, where there will be presented papers on INDUSTRIAL DERMATOSES.

Tuesday, April 28—10:00 A.M.

The Waldorf-Astoria, Lounge Restaurant

1. "Sulfonated Hydrogenated Castor Oil as a Detergent and Ointment Base"
Shepard Quinby, M.D., Buffalo
George W. Fiero, Ph.D., Buffalo (By invitation)
2. "Newer Considerations on Soap as a Dermatologic Problem"
Herman Sharlit, M.D., New York
Discussion of both papers: Eugene F. Traub, M.D., New York
3. "The External Use of 30%-50% Sulfur in Petrolatum in Various Dermatoses"
E. William Abramowitz, M.D., New York
Discussion: Frank C. Combes, M.D., New York
4. "Sulfonamide Therapy in Dermatology"
Maurice J. Costello, M.D., New York
Abraham M. Rubinowitz, M.D., New York (By invitation)
Simeon E. Landy, M.D., New York (By invitation)
Discussion: Earl D. Osborne, M.D., Buffalo
5. "Syphilis Prevalence in a Cancer Population"
Morton L. Levin, M.D., Albany
Louis C. Kress, M.D., Albany
Hyman Goldstein, Ph.D., Albany (By invitation)
Discussion: Isadore Rosen, M.D., New York

Scientific Program

The Committee: A. W. Martin Marino, M.D., *Chairman*, Brooklyn;
D. Dexter Davis, M.D., Brooklyn; and
Chairmen of Sections and Sessions

GENERAL SESSIONS

(*Dr. Marino presiding*)

The presentations at these Sessions will consist of one-half hour lectures without discussion. The meetings will start promptly at the hour specified. Members are requested to be in their seats at least five minutes in advance of the meeting time.

Tuesday, April 28—3:00 P.M.
The Waldorf-Astoria, Ballroom

Thursday, April 30—2:00 P.M.
The Waldorf-Astoria, Ballroom

Presiding at this session:

Colonel Charles M. Walson, Surgeon, Second Corps Area, Governor's Island
Samuel Adams Cohen, M.D., New York, representing the Metropolitan New York Chapter of the Association of Military Surgeons of the United States.

1. "Relations of Faulty Dentition to Deafness"
William P. Wherry, M.D., President, Nebraska State Medical Association, Omaha, Nebraska
2. "Transition of Civilian Doctors to Medical Officers of the Army"
Major General James C. Magee, The Surgeon General, U. S. Army, Washington, D. C.
3. "Lessons Learned from Physical Examinations of Registrants"
Colonel Leonard G. Rowntree, Chief Medical Officer of the National Selective Service Administration, Washington, D. C.
4. "The Physician's Role in Civilian Defense Program"
George Baehr, M.D., Chief Medical Officer, Office of Civilian Defense, Washington, D. C.

SYMPOSIUM

DISEASES OF THE CHEST

1. "Recent Advances in Tuberculosis of Special Importance to the General Practitioner" (The A. Walter Suiter Lectureship. This will be the fourth lecture to be delivered under this lectureship fund.)
Edgar Mayer, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical College, New York
2. "The Role of the Radiologist in the Diagnosis of Lesions Involving the Respiratory Tract"
Barton R. Young, M.D., Associate Professor of Radiology, Temple University School of Medicine, Philadelphia, Pennsylvania
3. "A Common Masquerading Lung Disease"
Richard H. Overholt, M.D., Thoracic Surgeon, New England Deaconess Hospital, Boston, Massachusetts
4. "The Role of the Bronchoscopist in the Diagnosis and Treatment of Diseases of the Bronchial Pulmonary Tract"
Arthur Q. Penta, M.D., Director of the Department of Bronchoscopy, Schenectady City Hospital, Schenectady

Reservations For the Annual Banquet

..... are now being made. Requests should be sent to Alfred M. Hellman, M.D., chairman, Banquet Committee, Medical Society of the State of New York, 292 Madison Avenue, New York City. Or, you can telephone—Murray Hill 3-9841. Tickets are \$5.00.

The banquet will be held in the Waldorf-Astoria Hotel on Tuesday, April 28, at 7:00 P.M.—a *must* occasion for everybody.

SECTION ON MEDICINE

Chairman.....
.....Scott Lord Smith, M.D., Poughkeepsie
Vice-Chairman.....
.....J. Stanley Kenney, M.D., New York
Secretary.....
.....Frederic William Holcomb, M.D., Kingston

Wednesday, April 29—10:00 A.M.

Charles B. Huggins, M.D., Chicago, Illinois (By invitation)
- Discussion of Symposium: Albert M. Crance, M.D., Geneva; J. Sydney Ritter, M.D., New York; Oswald S. Lowsley, M.D., New York

SESSIONS

SESSION ON HISTORY OF MEDICINE

Chairman . . . Emerson Crosby Kelly, M.D., Albany
Vice-Chairman . . . George Rosen, M.D., Brooklyn
Secretary . . .
Edward F. Hartung, M.D., New York

Wednesday, April 29—4:00 P.M.

The Waldorf-Astoria, Carpenter Dining Room

1. "Alexander Anderson, M.D., 1775—1870, The First Wood Engraver in America"
Walter B. Mount, M.D., Montclair, New Jersey (By invitation)
2. "The Yellow Fever Epidemic in New York City, 1795—1805"
Louis Faugeres Bishop, Jr., M.D., New York

Intermission—Epidaurian Oasis

3. "New York City in the History of American Ophthalmology"
George Rosen, M.D., Brooklyn
4. "Body Snatching in New York City"
Claude E. Heaton, M.D., New York

SESSION ON PHYSICAL THERAPY

Chairman . . .
Madge C. L. McGuinness, M.D., New York
Secretary . . . Harold J. Harris, M.D., Westport

Wednesday, April 29—2:00 P.M.

The Waldorf-Astoria, Ballroom

Address: "Physical Medicine in War and Defense"

Madge C. L. McGuinness, M.D., New York

1. "Physical Therapy in Heart Disease"
William G. Leaman, Jr., M.D., Philadelphia, Pennsylvania (By invitation)
- Discussion: Walter S. McClelland, M.D., Saratoga Springs; Washington Merscher, M.D., Watkins Glen; and Franz M. Groedel, M.D., New York
2. "Functional Disorders of the Foot and Their Treatment"
Dudley J. Morton, M.D., New York
- Discussion: Herbert C. Fett, M.D., Brooklyn; Paul N. Judson, M.D., Philadelphia, Pennsylvania (By invitation)

2. "Prevention of Tuberculosis in Children"
William J. Orr, M.D., Buffalo
Discussion: Fairfax Hall, M.D., New Rochelle; and Robert E. Plunkett, M.D., Albany

3. "Tuberculosis in Adolescents and Young Adults"

Ralph Horton, M.D., Oneonta

Discussion: James C. Walsh, M.D., Farmingdale; and Arthur M. Johnson, M.D., Rochester

4. "Factors in Obstetrical Care; Report of a Rural Study"

Henry R. O'Brien, M.D., Hartford, Connecticut

Discussion: Elizabeth Parkhurst, M.Sc., Albany (By invitation); and Earle G. Brown, M.D., Mineola

Wednesday, April 29—2:00 P.M.

The Waldorf-Astoria, Starlight Roof, 50th Street Terrace

SYMPOSIUM

PUBLIC HEALTH AND THE WAR

1. "Public Health Activities of New York City in Relation to National Defense"
John L. Rice, M.D., New York
2. "Syphilis and Gonorrhea Control"
William A. Brumfield, Jr., M.D., Albany
3. "Medical Aspects of Civilian Defense"
Henry van Zile Hyde, M.D., New York
4. "United States Public Health Service War Activities"
Claude C. Pierce, M.D., New York (By invitation)

SECTION ON RADIOLOGY

Chairman.....
.....Chester O. Davison, M.D., Poughkeepsie
Vice-Chairman.....

Secretary..E. Forrest Merrill, M.D., New York

Tuesday, April 28—10:00 A.M.

The Waldorf-Astoria, Carpenter Salon

SYMPOSIUM

CHEST FILM INTERPRETATION

Radiologists throughout the state have been asked to send in films of interesting, unusual, or puzzling cases in which the diagnosis has been proved by microscopic study, operation, or autopsy. Using these films and an abstract of the case history, there will be a discussion of chest film analysis.

Discussion Leaders: Ross Golden, M.D., New York; Marcy L. Sussman, M.D., New York

Wednesday, April 29—2:00 P.M.

The Waldorf-Astoria, Carpenter Salon

JOINT MEETING

WITH THE

TUMOR CLINIC ASSOCIATION OF THE STATE OF NEW YORK

1. "Three New Tools of Science"
Douglas F. Winnek, Mount Vernon (By invitation)
2. An interesting symposium on the treatment of cancer, and on tumor clinic problems, is being arranged by the Tumor Clinic Association of New York State. (Details will be announced later.)
Presiding: Frederick S. Wetherell, M.D., Syracuse

JOINT MEETING—SECTION ON SURGERY WITH THE SECTION ON MEDICINE

Wednesday, April 29—10:00 A.M.

The Waldorf-Astoria, Ballroom

SYMPOSIUM

MEDICAL CONDITIONS IN SURGICAL PATIENTS

1. "Management of Cardiac Patients Who Require Surgery"
Herrman L. Blumgart, M.D., Boston, Massachusetts (By invitation)
2. "Medical Aspects of Diabetic Surgery"
Howard F. Root, M.D., Boston, Massachusetts (By invitation)
3. "Surgery in the Aged"
Frederic W. Bancroft, M.D., New York
4. "The Role of the Liver in Surgery"
Allen O. Whipple, M.D., New York
5. "The Prevention and Treatment of Post-operative Pulmonary Complications"
Carl Eggers, M.D., New York
6. Summation
Donald Guthrie, M.D., Sayre, Pennsylvania (By invitation)

SECTION ON SURGERY

Chairman..Alfred H. Noehren, M.D., Buffalo
Secretary.....
....William Crawford White, M.D., New York

Thursday, April 30—10:00 A.M.

The Waldorf-Astoria, Ballroom

1. "Diagnosis and Treatment of Obstructive Jaundice"
John D. Stewart, M.D., Buffalo
Discussion: William D. Andrus, M.D., New York

New York

SURGERY IN FACIAL CANCER

Exhibit showing early and advanced cases of cancer of the face before and after operation with emphasis on plastic reconstruction. Statistical data and the results from the Skin and Cancer Unit of the New York Post-Graduate Hospital, Columbia University, New York City.

Walter A. Coakley, M.D., F.A.C.S.

Kings County Hospital
Brooklyn

PLASTIC AND MAXILLOFACIAL SURGERY EXHIBIT

Photographs of burns and skin grafts, prints of x-rays of fractures of facial bones including zygoma, mandible and maxilla; models of fracture of facial bones.

Jacques W. Maliniac, M.D.

New York

USE OF FREE GRAFTS AND FLAPS IN POSTTRAUMATIC LOSSES OF SKIN

Charts, photographs, and moulages illustrating a variety of skin injuries and losses; plans of repair in typical instances with special emphasis on prevention of disfigurement.

Fritz Spanier, M.D.

Staten Island
New York

FACIOMAXILLARY SURGERY

Moulages and photographs demonstrating

operations on maxilla, mandibula, palate and face (War injuries, cleft palate, protrusion tumors, etc.).

Joseph Kovacs, M.D.

Gerald H. Pratt, M.D.

New York Post-Graduate Hospital

ULCERS OF THE LEG

Differential Diagnosis. Conservative and surgical treatment.

Emanuel Goldberger, M.D.

Lincoln Hospital
New York

THE AV-LEADS (AUGMENTED UNIPOLAR EXTREMITY LEADS)

The exhibit illustrates the principles and technique of the Exhibitor's Augmented Unipolar Extremity Leads and demonstrates their applicability in the understanding of the eeg. patterns of axis deviation, ventricular hypertrophy, coronary thrombosis, pericarditis, pulmonary embolism, etc.

David Louis Engelsher, M.D.

New York

CONDITIONS RELATED TO ALLERGY AND ASTHMA

A schematic display revealing conditions and diseases that often precede asthma or are of an allergic basis requiring that type of study.

I. A. Brunstein, M.D.

Stuyvesant Polyclinic
New York

PREVENTION OF DISCOMFORT AND DISABILITY IN THE TREATMENT OF VARICOSE VEINS

Illustrations of "Before and After Treatment," with texts and sketches on technical procedures. Care of complications associated with the more advanced cases of varicose veins will be included.

Erich Seligmann, M.D.

Siegbert Bornstein, M.D.

I. Saphra, M.D.

Beth Israel Hospital
New York

SEROLOGIC DIAGNOSIS OF SALMONELLA INFECTIONS

Pictures and charts describing theory and technique of identification and classification of Salmonella organisms according to the Kauffmann-White Schema. Antigens and sera for practical demonstration of a simplified typing procedure.

UTEROTUBAL X-RAY SERIES. A NEW TECHNIC IN STERILITY DIAGNOSIS

This exhibit consists of a demonstration of the applicability of radio-opaque substances injected directly into the cervix of the uterus in order to visualize clearly the structure of the female genital tract. The simple technic is clearly described by means of drawings, photographs, and actual demonstration of many series of x-ray plates. This fractional method of viewing the female viscera is performed by a combined technic of fluoroscopy and radiography with the use of a new hysteroscope based on Beclere's original apparatus. The advantages of this procedure are lucidly and amply enumerated.

Brooklyn Hospital
Brooklyn

A METHOD OF DISINFECTION BASED ON CAPILLARY ELECTRICAL PHENOMENA ON BORDER MEMBRANES

Description and demonstration of a new method of testing and devising disinfectants and germicides.

A. Original photomicrographs of pathogenic microorganisms taken with the aid of fluorescent microscope will be exhibited, showing that substances having germicidal properties are adsorbed to the microorganisms according to their electrical charge and irrespective of their chemical composition. Photomicrographs will also demonstrate that the adsorption of germicides is increased with the raising of the dielectric constant of the solvent.

B. Charts of the fluorescent microscope and the high-tension apparatus for the testing of the electric charge of germicidal solutions will be shown and their principles will be described.

C. The chemical compositions of the various germicidal compounds devised and their efficacy on microorganisms will be shown on charts. The effect of the germicides on tissue cells will be described.

PLASTIC SURGERY AND CARE OF FACIAL INJURIES

Demonstration of principles and details of

That Wartime America may learn
how good posture helps
safeguard health . . .

S. H. Camp & Company
announces

**4th ANNUAL
CAMP
NATIONAL POSTURE
WEEK
MAY 4th to 9th**

In wartime it is more important than ever to teach the American public how improved posture can help safeguard health. For this reason, National Posture Week this year should be of more than usual interest to the medical profession.

In accordance with its increased significance, National Posture Week will be more widely publicized than ever. Press, radio, schools, colleges and civic groups will join in this important educational event.

We are confident that this 4th Annual National Posture Week will not only inspire more men and women to better posture . . . but will encourage those suffering from poor body mechanics to seek professional medical counsel. In achieving these aims, we hope to win again for this event the approval and support accorded it in the past by the medical fraternity.

PITOCIN

A product of modern research offered to the
medical profession by

No other footprints are exactly the same as those of this newborn infant. And no other oxytocic product duplicates Pitocin,* which helped bring this baby into the world. Pitocin contains the oxytocic principle of the pituitary gland with almost none of its pressor principle. Thus, it effectively stimulates uterine contractions without raising the blood pressure... an especially useful factor when labor is complicated by such conditions as nephritis and hypertension.

Pitocin is a familiar product in most delivery rooms. Obstetricians are pleased with its oxytocic reliability, its speedy action, the rarity of systemic reactions following its use. The Parke-Davis label assures accurate standardization.

Chief indications for Pitocin (alpha-hypophamine) are: medical induction of labor; stimulation of the lagging uterus during labor; prevention and minimizing of postpartum or late puerperal hemorrhage; and of blood loss following cesarean section or curettage. Literature on request.

5. Typical dental picture of an average NYA youth.

AMERICAN COLLEGE OF SURGEONS ANNOUNCES APRIL "WAR SESSIONS"

Between April 1 and May 1, inclusive, the American College of Surgeons will hold one-day "War Sessions" on problems of military service and civilian defense for medical and hospital personnel as follows in eleven cities (on April 3 in Albany at the DeWitt Clinton Hotel).

During March similar meetings were held in fourteen other cities.

The meetings open at 9:00 A.M. with panel discussions on treatment of war injuries for the medical profession and a forum on civilian defense as related to hospitals, led by a medical officer of the United States Office of Civilian Defense, for hospital personnel. From 10:45 to noon a joint meeting for physicians, surgeons, and hospital representatives is held, with medical officers of the United States Army, the United States

Navy, and the Office of Civilian Defense, as speakers. At the joint luncheon which follows, the Procurement and Assignment Service in relation to the medical profession and to hospitals is discussed by Major Sam F. Seeley, Executive Officer, a specially appointed delegate. In the afternoon, panel discussions for the medical profession are held on treatment of wounds of soft parts and on fractures, and for hospital representatives on special problems incident to the war as affecting hospitals.

The dinner meeting and the panel discussions which follow on treatment of burns and prevention and treatment of shock are for the entire group. The representatives of the army and the navy medical corps collaborate with civilian surgeons in leading these discussions.

VITAMIN B COMPLEX DEFICIENCY

*has numerous

Technical Exhibits

The Waldorf-Astoria, Ball Room Floor, April 27-30, 1942

THERE has never been a wider diversification of displays illustrating the services and supplies available to the medical profession than is scheduled for the annual meeting this year.

The Technical Displays are surrounded by the Scientific Exhibits. It may be suggested that the best way to view the exposition is to start at the entrance to the Basildon Room, follow through the Jade Room, Astor Gallery, East Foyer, the Ball Room Corridor, and the West Foyer.

Of special interest will be the "fresh tissue" exhibit and demonstration in the West Foyer which is under the direction of the pathology section.

Along this route you will find, in addition to the Technical Exhibits listed below, a wide variety of scientific presentations which no member attending this year's meeting will want to miss.

The Technical Exhibits are described in the following list. The brief description of them can only give a fraction of the information which is available at each of these booths. Admission to the exhibits and scientific sessions is limited to those presenting official badges which are available at the Registration Desk. There is no registration fee. Upon your arrival at the meeting go at once to the Registration Desk, obtain your badge and the exhibits will be open to you.

Abbott Laboratories, North Chicago (Booth 107), heartily invites you to drop in and discuss the newer products with their Abbott-trained representatives. Here you will find a comprehensive showing including large volume Intravenous Solutions and newly developed Venoclysis Equipment, Sulfonamides, Pentothal Sodium, Vitamins, Metaphens, etc. So! Stop in and see them!

American Hospital Supply Corporation, Chicago and New York (Booth 1). You will see interesting demonstrations of the ease, rapidity, and economy of plasma preparation with Baxter equipment, by both centrifugation and sedimentation methods. You will also have an opportunity to learn about the latest transfusion methods, and the merits of the Baxter Sulfanilamide and Alcohol-Dextrose solutions, two new products which have made an excellent therapeutic record. Also on display are new and exclusive American products and equipment, which have been the subject of so much favorable comment by the profession.

The Arlington Chemical Company, Yonkers, New York (Booth 86). The importance of amino acids in nutrition is the subject of discussion and research to a greater degree each year. Aminoids, a multiple amino acid preparation for oral administration, will be demonstrated by the Arlington Chemical Co. at their exhibit. Allergenic extracts of proteins, pollens, and fungi for diagnosis and desensitization of allergic conditions are also on display.

Arta Cosmetics, Inc., Bloomfield, New Jersey (Booth 105), will exhibit Sutra, the American Medical Association Accepted sunfilter cream.

Sutra is an easily absorbed cream—a shield against painful sunburn, blistering, and peeling. Imra, the modern odorless cosmetic depilatory which involves a new chemical principle in scientific depilation, will also be shown. At the same booth the Union Pharmaceutical Co., Inc., will display Saraka, a diet aid for use in common constipation.

W. A. Baum Co., Inc., New York (Booth 33), will feature two new items in the display of their complete line of Baumanometers and Latex replacement parts. An improved Air-Flo Control and Bulb of an entirely new design and construction and the new Kit-bag Model Baumanometer will be introduced at this meeting. You are cordially invited to visit their exhibit.

J. Beeber Company, New York (Booths 26 and 27).

The Bergman Associates, Brooklyn (Booth 102), present several features of their complete service to physicians and pharmaceutical concerns, including motion pictures, charts, and color transparencies. There will be a working demonstration of the production of animated films, color photography and medical drawing. A special display of cameras, etc., designed and built by The Bergman Associates for special purposes (including endoscopic motion pictures) is featured.

The Best Foods, Inc., New York (Booth 96). Interesting displays at their exhibit illustrate and describe the many uses of Nucoa, the wholesome vegetable margarine, composed of products only by American farmers. Nucoa and other Best Foods and Hellmann's products will be dis-

played at the booth, where Elsie Stark, Director of Home Economics Department, is in charge.

Bilhuber-Knoll Corp., Orange, New Jersey (Booth 51). Visit their exhibit where personal attention will be given to your discussions on Dilaudid, the quickly acting analgesic and cough sedative; Metrazol, the "Council Accepted" stimulant and restorative; Theocalcin, the myocardial stimulant and diuretic. Mr. Beakley, Mr. Delaney, and Mr. Stauber will be on hand and will welcome your visits and the opportunity to answer your questions pertinent to their original medicinal chemicals.

The Borden Company, New York (Booth 4). For news about Borden's scientifically designed infant foods visit their display. Biolac—a complete formula except for vitamin C. New Improved Dryco provides increased potencies of vitamins A and D, quicker solubility and maximum formula flexibility. Mull-Soy—emulsified food for infants allergic to milk, readily digestible, exceptionally palatable. Also Beta Lactose, Klim, Merrell-Soule Powdered Milks, and Borden's Silver Cow and Borden's Pearl Brand Irradiated Evaporated Milk.

Brewer & Company, Inc., Worcester, Massachusetts (Booth 81), produces a very fine line of enteric coated specialties, as follows: Thesodate (featured at their exhibit) enteric coated tablets and gelatin capsules for the treatment of Coronary Artery Disease; Luasmin enteric coated tablets and gelatin capsules for the relief of Bronchial Asthma; and enteric coated Codeine Phosphate Tablets ($\frac{1}{4}$ grain), for the relief of useless coughs.

Burroughs Welcome & Co. (U. S. A.) Inc., New York (Booth 72), presents a selected group of fine chemicals and pharmaceutical preparations, together with new and important therapeutic agents of special interest to the medical profession.

Cambridge Instrument Company, Inc., New York (Booths 73 and 74). Physicians interested in Cardiology should not fail to see the new Cambridge Research Model Portable Electrocardiograph-Stethograph which is being shown at their exhibit together with a complete display of Cambridge cardiac diagnostic instruments. Here may be seen mobile, stationary, and portable models of Cambridge Electrocardiographs and Electrocardiograph-Stethographs, available to serve large or small hospital, clinic or private office. A new portable instrument, which indicates or records blood pressure continuously, will also be on display.

Camel Cigarettes, New York (Booths 14 and 15), will exhibit large detailed photographs of equipment used in comparative tests of the five largest-selling brands of cigarettes. These tests proved that Camels burn slower and contain less nicotine in the smoke than other cigarettes. Representatives will be available to discuss this research.

Cameron Surgical Specialty Co., Chicago and New York (Booth 37). See the Cameron Flexible Gastrosopes, Bronchoscopes, Esophagoscopes, Laryngoscopes, Binocular Prism Loupe, Color Flash Clinical Camera, Mirrolite, and other new developments in electrically lighted Diagnostic and Operating Instruments for all parts of the body. As all instruments work from dry cells as well as electric light current, in the event of a "black out" or emergency failure of electric light current the surgical work can proceed regardless. Of special interest are the new Electro-Surgical Units (the genuine Radio Knives) for cutting, coagulating, desiccating, and fulgurating in all sizes from the office model Cauteradio to major Hospital Units with abundance of power for radical surgery. New York Sales Office, 250 West 57 St., New York City, convenient for service at all times for doctors in the greater New York area.

S. H. Camp & Company, Jackson, Michigan (Booth 75), will exhibit a reproduction of the Camp Transparent Woman as the central theme of their display. The company's authorized dealers are equipped to serve patients for the various supports prescribed by physicians. The complete line of merchandise for prenatal, postnatal, visceroprotic, sacroiliac, hernial, and other specific conditions will be shown. Experts from the Camp staff will be in attendance to answer specific questions.

Canadian Radium & Uranium Corporation, New York (Booth 30). A visit to this exhibit will remind medical men that all needs for radium in the Western Hemisphere can now be supplied wholly within this hemisphere. This situation follows the successful development of the rich reserves of ore at Great Bear Lake in the Canadian subarctic and the completion of large modern refining facilities at Fort Hope, Ontario. As sole sales agent for the output, this company offers this high-purity radium in any form and any type of container. For further interesting details, call at the booth.

Ciba Pharmaceutical Products, Inc., Summit, New Jersey (Booth 9). There will be found the well-known Ciba specialties. Latest information concerning Perandren, Di-Ovoeylin, and our other gynecogenic preparations will be available, together with literature describing their clinical application where androgens and estrogens are indicated. Representatives of the firm will be in attendance and will be glad to answer any questions in regard to the products displayed.

Cochrane Physicians' Supplies, Inc., New York (Booth 40), have endeavored to make their exhibit most attractive and interesting and well worth visiting. On display will be surgical and diagnostic instruments, cauteries, furniture, sterilizers, dressings, glassware, lamps, syringes, suture and hypodermic needles, physicians bags, pumps, rubber goods, and short-wave and galvanic machines.

The Cream of Wheat Corporation, Minneapolis, Minnesota (Booth 22), will exhibit enriched 5-

ERTRON

Reg. U.S. Pat. Off.

PRICES REDUCED

Your acceptance of ERTRON, doctor, together with the improved production facilities in our new laboratories, enables us to announce to the medical profession a reduction of ONE-THIRD in the price of ERTRON.

More doctors than ever before are effectively treating arthritis with ERTRON. This increased volume has made possible economies in our operating costs. We are passing these savings on to your patients as another contribution from our laboratories to the crusade against the ravages of arthritis.

The new retail prescription price of ERTRON, effective immediately, is:

BOTTLES OF 100 \$8.00 BOTTLES OF 50 \$4.50

ERTRON is made only in the distinctive two-color, hard gelatin capsule.

ERTRONIZE THE ARTHRITIC

Of the many therapeutic measures which have been advanced for the treatment of arthritis, ERTRON stands out for its proven safety and effectiveness.

An outline of suggested dosage and administration is available on request.

Products of Nutrition Research Laboratories are promoted only through the medical profession.

NUTRITION RESEARCH LABORATORIES
4210 Peterson Avenue, Chicago, Illinois

Minute "Cream of Wheat." This improved cereal is completely cooked in five minutes and has been fortified with additional Vitamin B₁ (Wheat Germ and Thiamin), iron, calcium, and phosphorus.

The Denver Chemical Mfg. Company, New York (Booth 78). Galatest will be exhibited and demonstrated. A dry reagent for diabetic sugar, Galatest is simple, accurate, economical. One drop of urine on a small quantity of powder and the reaction is completed instantaneously. No test tubes, no measuring, no burners.

Doak Company, Inc., Cleveland (Booth 41). Physicians are cordially invited to visit their exhibit where the well-known line of Doak Dermatological Specialties will be displayed. Most prominent among these are Lotio Alsulfa (liquid cream of colloidal sulfur), Tersus (liquid skin cleanser pH 6, 5, considered nonallergic), Heliobrom and Heliobrom Lotion (indicated in treatment of pruritus), Cot-Tar (an elastic coating of tar). Doak Company also exhibits the original colloidal sulfur (Sulfur-Doasporal) ampules for intramuscular and intravenous injections in treatment of arthritis.

The Doho Chemical Corporation, New York (Booth 46), Animated Pathological Ear Exhibit—the Auragan Exhibit consists of a model of the human auricle four feet high together with a series of twenty-four three-dimensional ear drums, modeled under the supervision of outstanding otologists. Each of these drums depicts a different pathologic condition based upon actual case observation and prepared, in so far as possible, with strict scientific accuracy so as to be highly instructive and interesting to all physicians.

Effervescent Products, Inc., Elkhart, Indiana (Booth 52), will display Clinitest—the new 1 minute tablet test for sugar in the urine. Expert technicians will be on hand to demonstrate the simplicity, speed, and reliability of this new improved method of qualitative urine-sugar analysis.

J. H. Emerson Co., Cambridge, Massachusetts (Booth 108), will demonstrate the wide range of usefulness of the Emerson Resuscitator, now obtainable in a variety of models, including the oxygen-operated hospital and portable units together with the new hand-operated field units; as well as the Emerson Respirator, now the demonstrated leader in the respirator field, the Humidox Humidifier, and the Suction-Pressure Apparatus.

Endo Products, Inc., Richmond Hill, New York (Booth 80), cordially invites the members of the Medical Society of the State of New York, attending the Convention, to visit their exhibit. Trained representatives will be on hand to discuss its complete line of pharmaceuticals and ampule solutions, including Estromone, Entromone, and other hormone products which have been so well received by the profession in the past. We also extend a cordial invitation to

visit our laboratories in Richmond Hill to view the making and filling of sterile solutions in ampules and vials.

H. G. Fischer & Company, Chicago and New York (Booth 110), are displaying their new models of x-ray and short-wave apparatus which are so distinctive. The complete H. G. Fischer Mfg. Co. line includes shockproof x-ray apparatus, short-wave units, combination cabinets, galvanic and wave generators, ultraviolet and infrared lamps and many other units, accessories, and supplies. Physicians are invited to ask for demonstrations of apparatus in which they are interested and to consult with Fischer representatives regarding technics made available by Fischer apparatus.

C. B. Fleet Co., Inc., Lynchburg, Virginia (Booth 59). Phospho-Soda (Fleet) has been an ethical product for over half a century. It is a highly concentrated, purified, aqueous solution of the two U. S. P. phosphates in stable form. It is nontoxic, rapid but mild in action, without irritation of the gastric or intestinal mucosa. It is indicated in hepatic and gallbladder dysfunctions, and when a thorough eliminating and cleansing action is desired on the upper and lower gut.

General Electric X-Ray Corp., Chicago (Booths 16 and 17). To hospital administrators and physicians who desire a fresh perspective of their present x-ray facilities, in view of prevailing standards in modern medical practice, we offer this suggestion: Arrange to have a G-E x-ray representative call, at your convenience to give you the benefit of his knowledge and experience in a survey of this kind. New York State has two G-E x-ray branch offices, one in New York City and the other in Rochester. A manager, twelve salesmen, and ten servicemen work out of the New York office, and a manager, five salesmen, and four servicemen are stationed in Rochester. You can rely on them to offer you practical and helpful suggestions.

Gerber Products Company, Fremont, Michigan (Booth 79). Gerber Baby Foods have grown in variety so fast that we will welcome your call at our booth to see the latest arrivals.

Otis E. Glidden & Co. Inc., Evanston, Illinois (Booth 104), will exhibit their product, Zymenol, a brewer's yeast emulsion for constipation and colitis. The booth will be in charge of Mr. Roy Erickson, eastern supervisor for Otis E. Glidden & Co.

Hanovia Chemical & Mfg. Co., Newark, New Jersey (Booth 67), will exhibit a complete line of new self-lighting ultraviolet light quartz lamps. Don't fail to ask for a demonstration of the new Aero-Kromayer cooled by air instead of water. Short and Ultra Short Wave equipment and a complete line of Sollux Radiant Heat lamps will be shown. Courteous and competent representatives will be on hand to greet you.

FOR BLOOD DONORS

...The hemoglobin regeneration rate increases nearly 50% and the recovery period is drastically shortened when small amounts of iron are administered.†

HEMATINIC PLASTULES*

Hematinic Plastules provide iron in the *ferrous* state quickly available for conversion into hemoglobin. They are easy to take and well tolerated. Each Plastule contains dried ferrous sulphate U.S.P.X. 5 gr. and yeast concentrate .75 gr., supplied in bottles of 50, 100 and special hospital size of 1,000. Also available with Liver Extract.

///

Ferrous Iron Sealed from the Air but not from the Patient

THE BOVININE COMPANY • CHICAGO, ILLINOIS

Harold Surgical Corp., New York (Booth 58), will exhibit a new model shockproof X-ray apparatus with a motor-driven Table and automatized controls. Also on exhibition will be a Physiotherapy apparatus and Electro-cardiographic apparatus. A special feature this year will be the establishing of an Air Raid Defense Department and physicians may obtain complete information at this booth. In charge will be Mr. S. Mehlinger and Mr. J. Shnitzer.

H. J. Heinz Co., Pittsburgh (Booth 49). The Heinz exhibit featuring Strained and Junior Foods merits your thoughtful attention if you prescribe for infant feeding or adults on soft diets. The popular Nutritional Charts have something new added—a section on the "Application of the Science of Nutrition to Dietetics." While you're at the exhibit, register for the tenth edition. Mr. F. B. Heard and Mr. S. R. Yarrow are the Heinz representatives.

Hoffmann-La Roche Inc., Nutley, New Jersey (Booth 2).

Holland-Rantos Company, Inc., New York (Booth 94). Modern contraceptive technique will be graphically illustrated with a motion picture, and all the various contraceptive materials including both the Koromex and Hyva diaphragms, Koromex jelly and H-R Emulsion cream, together with the most complete line of contraceptive specialties, will be demonstrated at the booth of the Holland-Rantos Company. Displayed, also, will be the new Rantex Surgical Masks and Caps, now being used by hospitals all over the country. They represent an outstanding development.

Horlick's Malted Milk Corporation, Racine, Wisconsin (Booth 18), cordially invites you to visit their booth and enjoy a refreshing serving of chocolate malted milk. This palatable, delicious and easily digested food-drink is indicated as a supplement to liquid and semiliquid diets. It is basic nutrition because it is a scientifically well-balanced combination of proteins and carbohydrates of full-cream milk and choice grains.

Hynson, Westcott & Dunning, Inc., Baltimore (Booth 47), will have an exhibit featuring Mercurochrome and various pharmaceutical specialties of their manufacture. There will also be a display of diagnostic apparatus and ampule solutions which have been developed in the firm's laboratories in cooperation with physicians. Competent representatives will be in attendance to demonstrate the products. Literature and samples will be available to physicians who are not already familiar with products exhibited.

Jones Metabolism Equipment Company, New York (Booth 42), invites you to see the original waterless metabolism apparatus. The exclusive features of the Jones include a double slope tracing which eliminates the possibility of technical errors; a simplified and accurate slide rule for calculations, and the life-time guarantee for accuracy greater than 99 per cent. The twenty-

three years of experience of the Jones Metabolism Equipment Company have made it possible for them to produce a foolproof, simple, and accurate machine.

Kellogg Company, Battle Creek, Michigan (Booth 77). Kellogg's ready-to-eat cereals have an important part in the national nutrition program. Corn Flakes and Rice Krispies are included freely in wheat-free and low residue diets. Pep has been enriched with vitamins B₁ and D, the vitamins so frequently lacking in the average American diet. Kellogg's other whole wheat and bran cereals—Wheat Krispies, Krumbles, Shredded Wheat, All-Bran and Bran Flakes—are rich in minerals and vitamin B, too. Ask for your set of medical reprints covering recent research with these products.

Charles B. Knox Gelatine Co., Inc., Johnstown, New York (Booth 10). Their exhibit features the medical and dietary uses of Knox Plain Sparkling Gelatine. Attendants will gladly discuss the protein value of gelatine and explain how the production and laboratory control makes Knox Gelatine a quality product essential for special dietary use. Literature, including dietaries and recipes, is free.

Lederle Laboratories, Inc., New York (Booth 60), will feature leading medical products: Hay Fever; Tuberculin Patch Test; Tetanus Toxoid and the complete line of B Complex vitamins including Vi-Ferrin (a preparation of ferrous sulfate and B Complex) introducing Lederle's new Vitamin B Tablets.

Thomas Leeming & Company, Inc., New York (Booth 53), invite you to inspect a new exhibit incorporating full color photographs of a number of pathologic skin conditions frequently encountered in practice. These photographs, from the collection of an outstanding dermatologist, demonstrate the typical lesions in each of the conditions, thus facilitating accurate diagnosis. The exhibit deals with the use of Calmitol in the control of pruritus associated with such conditions. Also exhibited will be two recently introduced preparations, Amend's Solution, an aqueous iodine solution for internal administration, notable for its palatability and low toxicity, and Magmasil, a unique magma of magnesium trisilicate which has been called "the closest approach to the theoretically ideal antacid" in the treatment of peptic ulcer.

Lepel High Frequency Laboratories, Inc., New York (Booth 39), will exhibit their complete line of physical therapy equipment including their latest developments in short-wave generators, ultraviolet lamps, and their new combination low voltage equipment. You are cordially invited to visit their booth and have the representative demonstrate these new models including the electro surgery.

The Liebel-Flarsheim Co., Cincinnati, Ohio (Booth 43). Stop and see the latest models of L-F Short and Ultra-Short Wave Generators. . . as well as the famous Bovie Electrosurgical Units and other newly developed, interesting

Solution Sodium Ascorbate Squibb

In Surgical Wound Healing

Wound in patient with Vitamin C deficiency shows failure to heal after 10 days

Healing after administration of 1000 mg. ascorbic acid intravenously daily for 10 days

VITAMIN C has been shown to be an essential factor in wound healing. Reports of its value have led to its administration both pre- and post-operatively in cases where a deficiency of ascorbic acid is known to exist.

When such a deficiency is apparent and when the patient is allergic to or dislikes foods containing Vitamin C, or where there is an interference with assimilation of the vitamin, ascorbic acid supplementation is indicated.

Solution Sodium Ascorbate Squibb (for intravenous injection) is of particular value for those undergoing surgical procedures. It is likewise indicated in severely ill patients and those in whom some condition such as gastric anacidity or intestinal disease may result in faulty utilization of the vitamin.

Solution Sodium Ascorbate Squibb is supplied in boxes of 6 and 25 ampuls, each containing sufficient material for the withdrawal and administration of 1 cc.—containing an amount of sodium ascorbate equivalent to 100 mg. ascorbic acid. Also in boxes of 6 x 1 cc. ampuls containing the equivalent of 500 mg. ascorbic acid per cc.

ALSO AVAILABLE

Ascorbic Acid Squibb (Cevitamic Acid, Vitamin C Crystalline) *for oral use*—Supplied in 25-mg., 50-mg. and 100-mg. tablets. One 25-mg. tablet, containing 500 U.S.P. XI units of Vitamin C, is equivalent in Vitamin C activity to about 1½ ounces of fresh orange juice. All sizes are supplied in bottles of 40, 100 and 500 tablets.

For literature address the Professional Service Department, 745 Fifth Ave., New York, N. Y.

E. R. SQUIBB & SONS

Manufacturing Chemists to the Medical Profession Since 1858

Physical Therapy apparatus and accessories. It will be a pleasure to demonstrate this modern equipment to you and the time spent at Liebel-Flarsheim will prove well worth your while.

Loeser Laboratory, Incorporated, New York (Booth 65), a subsidiary of the Wm. S. Merrell Company, offers an unusually interesting exhibit on ampules for intravenous and intramuscular injection. The high quality and standardized potency of these products have gained wide recognition among many members of the profession. A cordial welcome awaits you at their booth.

The Maltine Company, New York (Booth 12) will display, as part of their exhibit, the new quart, economy size of Maltine with Cod Liver Oil. The exhibit will show the care and precision used in selecting the fine materials that are included in the manufacture of this widely known product.

T. H. McKenna, Inc., New York (Booths C and D), will have a complete composite display of all the new and standard books of all medical publishers. In the belief that it will be a convenience to be able to examine the books of all publishers in one joint exhibit, the various publishers have cooperated in the arrangement of this exhibit.

Mead Johnson & Company, Evansville (Booths 34, 35 and 36). "Servamus Fidem" means We are Keeping the Faith. Almost every physician thinks of Mead Johnson & Company as the maker of Dextri-Maltose, Pabulum, Oleum Percomorphum, and other infant diet materials. But not all physicians are aware of the many helpful services this progressive company offers physicians. A visit to their exhibit will be time well spent.

The Medical Film Guild, New York (Booths 20 and 21).

Merck & Co., Inc., Rahway, New Jersey (Booths 69 and 70). We hope every doctor registered will visit this exhibit. The representatives present will be pleased to inform interested physicians regarding the clinical applications of the parasympathetic stimulant, "Mechoyl," and the convenience of the inhalation anesthetic, "Vinethene," for short surgical procedures. Literature on the vitamins, B₁, C, Riboflavin, and Nicotinic Acid will also be available.

Mooradian High Frequency Laboratories, Bogota, New Jersey (Booth 24), will be glad to welcome you at their exhibit and discuss any problems that you may have in reference to high frequency electromedical and electrosurgical apparatus. They will have on display the latest developments in short-wave apparatus, as based on their twenty-five years experience in the field.

The Mutual Pharmacal Company, Inc., Syracuse, New York (Booth 29), will exhibit special products such as: Tablets Be-Vi-Plex, Vita-Liv-Ferin. Almutal, Elixir Sedmutal No. 2, Estro-

genic Substance, various vitamin preparations and other products of special interest.

National Livestock and Meat Board, Chicago (Booth 8), invites you to visit their display portraying the importance of Meat as a source of the B vitamins. Wax models of a normal diet featuring the thriffter meat cuts will also be shown. Register for new twenty-four page book, *Better Nutrition for the Nation*, and other literature.

New York Medical Exchange, New York (Booth 38). Has the draft board worked havoc with your staff of physicians? If so, you can replace them from among the candidates whose histories may be seen at the exhibit of the New York Medical Exchange. You can also see the credentials of nurses, technicians, secretaries, record-room librarians, etc.

Nutrition Research Laboratories, Chicago (Booth 76), will show by means of x-rays, transparent photographs, wax models, and scientific literature the important types of chronic arthritis and the response of these to Ertron. The therapeutic advantages of Bezon, a whole natural vitamin B complex, are also depicted.

Ortho Products, Inc., Linden, New Jersey (Booth 87), will feature the Ortho Line, the physicians' line. It will be decorated with line drawings of scenes from our laboratory. The exhibit features the scientific background of their products, stressing the importance of medical and clinical research as applied to products of this kind. In attendance will be P. B. Hofmann, president; B. J. Todd, vice-president; and F. B. Whitlock, eastern divisional manager.

Paine Hall School, New York (Booth 66).

Parke, Davis & Company, Detroit, Michigan (Booth 4), will feature the sex hormones, Theelin and Theelol; antisyphilitic agents, such as Mapharsen and Thip-Bismol; posterior lobe preparations, including Pituitrin, Pitocin, and Pitressin; and various Adrenalin Chloride Preparations.

The E. L. Patch Company, Stoneham, Massachusetts (Booth 32), will exhibit some of its specialties, including Gadoment, Gadolets, and Kondremul. Patch Company representatives will be glad to greet their friends in the profession and give them full information concerning these and other Patch products.

The Pelton & Crane Company, Detroit, Michigan (Booth 97), are exhibiting Sterilizers, Operating Lights and Cuspidors, specially designed for use in the industrial clinic and first-aid room, as well as general practitioners' offices. Featured is the popular Tri-Plex combination with double storage cabinet, recessed instrument sterilizer and self-contained automatic autoclave. Mr. I. H. Fell, in charge.

Smoothage

... A SUCCESSFUL CONSTIPATION THERAPY

The correction of faulty elimination requires that the bowel mucosa be treated with the utmost consideration

It is the smoothage of METAMUCIL-2 which has this corrective effect METAMUCIL-2 is a radical departure from the old-time constipation "cures"—the irritating chemicals, dehydrating salines, scratchy roughage, gummy resins and vitamin-depleting oils

METAMUCIL-2 provides smoothage—soft demulcence which protects the mucosa against irritation, and encourages natural elimination by physiologic reflex action.

For corrective, protective smoothage, prescribe—

Ethical Pharmaceuticals Since 1888

CHICAGO

New York Kansas City San Francisco

SEARLE

Pet Milk Sales Corporation, St. Louis, Missouri (Booths 61, 62, 63 and 64), will display an actual working model of a milk condensing plant in miniature. This exhibit offers an opportunity to obtain information about the production of Irradiated Pet Milk and its uses in infant feeding and general dietary practice. Miniature Pet Milk cans will be given to each physician who visits the Pet Milk Booth.

Petrogalar Laboratories, Inc., Chicago (Booth 89), offer, in addition to samples of the Five Types of Petrogalar, an interesting selection of descriptive literature and anatomical charts. Ask the Petrogalar representatives to show you the Habit Time booklet. It is a welcome aid for teaching bowel regularity to your patients.

Philip Morris & Co., Ltd., Inc., New York (Booth 25), will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hydroscopic agent, are less irritating than other cigarettes. Their representative will be happy to discuss researches on this subject, and problems on the physiologic effects of smoking.

The Chas. H. Phillips Chemical Co., New York (Booth 106). Phillips' Milk of Magnesia, a standard to the medical profession for more than three generations, deserves consideration as a superior agent for securing the desired level of stomach acid in cases of peptic ulcer. Visit their exhibit to discuss new and startling concepts on antacid therapy.

The Prometheus Elec. Corp., New York (Booth 103).

The Radium Emanation Corporation, New York (Booth 91), will exhibit a wide variety of instruments and applicators used in modern radium therapy, including permanent and removable composite, leakproof Radon Seeds. The advantages of these seeds will be demonstrated by magnified sections showing their constructions in detail.

Ralston Purina Company, Inc., St. Louis, Missouri (Booth 31), cordially invites physicians to visit their exhibit to see Miniature Ralston Cereal Mill, Instant Ralston Prepared; to register for dietary literature on Ralston and Instant Ralston; for Obesity and Allergy Diets; for Food Diaries and Charts; for samples, Ralston, Instant Ralston, Ry-Krisp, Shredded Ralston.

Ritter Company, Inc., Rochester, New York (Booths 5, 6, and 7), will feature its Ear, Nose and Throat Units, together with the Motor Chair, both of which were introduced to the medical profession about eighteen months ago. In addition the following items will be shown: Sterilizers, Bone Surgery Engines, X-rays, Compressors, Fluorescent Light, and Stools. Ritter representatives from Rochester will be in attendance, in addition to territory representatives.

S.M.A. Corporation, Chicago (Booth 90). Among the technical exhibits at the convention this year is an interesting new display, which represents the selection of infant feeding and vitamin products of the S.M.A. Corporation. Physicians who visit this exhibit may obtain complete information, as well as samples, of S.M.A. Powder and the special milk preparations—Protein S.M.A. (Acidulated), Alerdex, and Hypo-Allergic Milk.

Safety First Supply Company—E & J Resuscitator, Pittsburgh, Pennsylvania (Booth 56). The latest models of the E & J Resuscitator—Inhalator-Aspirator will be on display at this exhibit. Members of the Society are cordially invited to witness demonstrations of this ingenious automatic breathing machine and hear something of its excellent record in the many fine clinics where it is in use.

Sanborn Company, Cambridge, Massachusetts (Booth 13). Outstanding new apparatus for cardiac diagnosis and research will be shown at the Sanborn Company exhibit: The Tri-Beam Stetho-Cardiette, which permits simultaneous phonocardiographic, electrocardiographic, and sphymographic recordings, plus amplified auscultation; and a new blood pressure and oscillographic attachment which produces simultaneous registration of the oscillographic waves and Karatkov sounds. Also on display will be the Waterless Metabolism tester for 1942; and the Cardiette, Stetho-Cardiette and Cardioscope.

Sandoz Chemical Works, Inc., New York (Booth 11). Physicians will be interested in Synergen (ergotamine tartrate) for the dramatic relief of migraine headache. Newly released products include Syrup Neo-Calglucon (calcium gluconogalactogluconate), a palatable, highly concentrated preparation for oral calcium therapy readily absorbed from the digestive tract; Cedilanid, a stable preparation of lanatoside C, a crystalline glycoside from Digitalis Lanata not present in purpura. Other members of the Sandoz group of pure cardioactive glycosides include Digilanid, Strophosid, Scillaren and Scillaren-B. Also displayed are Bellergal, Belladenal, and Bellafoline—sedatives of the neurovegetative system; Calglucon Effervescent Tablets and Chocolate Flavored Tablets—the original calcium gluconate products; Neo-Calglucon Ampuls—the improved preparation for parenteral calcium therapy.

Saratoga Springs Authority, New York (Booth 3)

Schering Corporation, Bloomfield, New Jersey (Booth 71). All the highly advanced Schering hormones are on display at the Schering exhibit, which is practically a survey of recent endocrine progress. In addition, there are some other particularly interesting products such as Sulamyd (Sulfacetimide) for the treatment of urinary tract infections, and Sulfadiazine-Schering, most efficient sulfonamide for pneumonia. Members of the Medical Research Division will be present and welcome discussion of problems.

WORCESTER, MASS.

PHARMACEUTICAL CHEMISTS SINCE 1852

Schering & Glatz, Inc., New York (Booths 44 and 45). New technics in intravenous infusion therapy are described in special service bulletins which will be available for visitors at the Sterisol Division exhibit of Schering and Glatz, Inc., manufacturers of dextrose and saline solutions in Sterisol Ampoules. Laboratory-trained attendants will demonstrate these procedures, including a simple method of eliminating air from the tubing when getting an infusion of dextrose ready.

G. D. Searle & Co., Chicago (Booth 109), will show a number of the new Products of Searle Research which have contributed so much to the recent armamentarium of the physician. Products such as Searle Aminophyllin, Metamucil-2, Ketochole, Furmerane, Floraquin, Gonadophysin are results of this research which will shortly be greatly expanded in the new Searle Research Laboratories now nearing completion. An illustration of the new laboratories will be featured in the exhibit.

Sharp & Dohme, Inc., Philadelphia (Booths 83 and 84), will have their modern display featuring "Lyovac" Normal Human Plasma, other "Lyovac" biologicals and biological specialties. There will also be on display pharmaceutical specialties, including the new Liquid "Digitol" and Tablets "Digitol" which are clinically standardized on humans, "Delvinal" Sodium, "Propadrine" Hydrochloride products, "Rabelon," "Depropanex," and "Prohexinol." A cordial welcome awaits all visitors.

Smith, Kline & French Laboratories, Philadelphia (Booth 95), again welcome the opportunity to display their products, including Benzadrine Inhaler, Benzadrine Sulfate Tablets, "Paredrine Hydrobromide Aqueous," and Pentanucleotide, to the members of the Society. Their representatives will be only too glad to discuss the products exhibited and will endeavor to answer any questions that may arise concerning them.

C. M. Sorensen Company, Inc., New York (Booth 50). It will be their pleasure to present for your inspection several new models of treatment outfits covering ear, nose, and throat work, including ether and suction apparatus, portables for bedside use, office and surgical requirements adequately met in these new smart productions.

E. R. Squibb & Sons, New York (Booth 88), will endeavor to convey scientific and pertinent information about some of their most important products by striking visual methods. Numerous photographs, charts, and demonstration packages will graphically point up the important features of these products, among which will be included new additions to their Vitamin, Glandular and Specialties lines. Well-informed representatives will be on hand, moreover, to welcome visitors and to furnish further information on the products displayed.

Frederick Stearns & Company, Detroit, Michigan (Booth 54). Doctors are cordially invited to visit their attractive convention display to view

and discuss outstanding contributions to medical science developed in the Scientific Laboratories of Frederick Stearns & Company. Their professional representatives will be pleased to supply all possible information on the use of such outstanding products as Neo-Synephrin Hydrochloride for intranasal use, Mucilose for bulk and lubrication, Ferrous Gluconate, Potassium Gluconate, Gastric Mucin, Susto, Trimas, Appella Apple Powder, Nebulator with Nebulin A, and their complete line of Vitamin products.

The Sun-Rayed Company (Div. Kemp Bros. Packing Co.), Frankfort, Indiana (Booth 82), producers of Kemp's Sun-Rayed Brand Tomato Juice. The natural, pasteurized juice of a special strain of Indiana tomatoes, sun-ripened on the vines and U. S. Government graded. The whole, carefully cored tomato is converted into juice by Kemp's patented process No. 1,746,657, which utilizes all the tender solids for high retention of vitamins A, B₁, and C, insures nonseparating color and never-thin-or-watery consistency. Samples served at booth. Representative in charge: Seggerman Nixon Corporation, 111 Eighth Avenue, New York, Mr. Frederick J. Nixon.

Taylor Instrument Companies, Rochester, New York (Booth 48). The Tycos Aneroid Sphygmomanometer with hook-type cuff will be featured at this exhibit. Of particular interest to doctors will be the Tycos Mercurial Sphygmomanometer and the related "lag error demonstration" showing the accuracy with which Tycos Mercurial Sphygmomanometers operate. Mr. R. F. Roda of the Medical Sales Department and Mr. Edward Hurlburt of the Advertising Department will be in attendance.

Therm-O-Rite Products Company, Buffalo, New York (Booth 98).

U. S. Vitamin Laboratories, New York (Booth 55).

Vegex Corporation, New York (Booth 28).

Walker Vitamin Products, Inc., Mt. Vernon, New York (Booth 57), Ethical Vitamin Specialties as well as a complete line of standard vitamin tablets are exhibited by this firm. Featured items are their Mineralized Vitamin Tablets, their capsules of Dicalcium Phosphate with Vitamins B-C-D, and their high potency Vitamin B Complex Products.

Wallace & Tiernan Products, Inc., Belleville, New Jersey (Booth 19). Azochloramid is an organic chloramine, capable of killing all types of microorganisms upon a wound without damage to vital tissue cells. Distinguished from all other chlorine germicides by its remarkable stability this preparation is virtually nonirritating and nontoxic. It is both fat and water soluble. Azochloramid is used in the treatment of all types of infected wounds and cavities. As a prophylactic agent in postoperative and traumatic wounds it has proved to be of great value.

The Wander Company, Chicago (Booth B).

Q. I've heard that canners just use the surplus crops. Is that true?

A. No. As a matter of fact, many of the varieties used for canning can not be obtained in any other form. Most canners contract for their crops for canning, months in advance. They usually specify the variety of fruit or vegetables wanted. And in many cases this means furnishing seeds or plants especially developed for their purposes. (1)

ENDO PRODUCTS, INC., RICHMOND HILL, NEW YORK

WORKMEN'S COMPENSATION AND THE PHYSICIAN

By Henry H. Jordan, M.D.

This manual is presented as a guide for the general practitioner and the insurance carrier in the handling of compensable injuries. It does not intend to compete with text books on the subject matter. Its chief aim is to illuminate those aspects and problems which, in the management of disabilities covered by workmen's compensation, differ from the familiar considerations in the treatment of non-compensable injuries and diseases. The subject matter is limited to general diagnostic and therapeutic problems, typical phases of the workmen's compensation procedure. This includes a discussion of questions such as the aggravation of pre-existing disease, the causal relation between injury and disability, and expert opinion and disability evaluation.

Industrial and railway surgeons may refer to the difficult problems of causal relation and of aggravation of pre-existing disease in the pertinent chapters.

The book is written in plain language and should be intelligible to the non-medical officials and employees of insurance companies, to lawyers, to industrial commissioners and referees of the labor departments who must decide compensation cases.

California WINES *invite attention*

IN AMERICA TODAY, the wines of our own country are used nine to one over foreign wines.

In fact authorities qualified to speak believe states like California and New York are producing wines of outstanding quality.

This quality begins with the grapes themselves. For example, in California's 700-mile vineyard belt there occurs a range of soils and climates in which the world's finest wine grapes are grown. Somewhere in the state each grape variety finds its ideal setting and comes to perfect ripeness each year.

Just as essential, American wine-growing skills and facilities have now advanced over any before known in this country. Special methods of grape selection, temperature control, and sanitation, continuing laboratory tests, and spotless modern equipment today aid the wine-grower in the United States.

In every way California and New York wines conform to the most rigid state and Federal standards of quality. All are well developed. True to type.

And these fine wines are moderate in price—perhaps an important point to many people who now find wines of Europe too expensive.

This advertisement is printed by the wine growers of California acting through the Wine Advisory Board, 85 Second Street, San Francisco. The non-profit Wine Advisory Board invites your requests for further information about California wines.

Women's Medical Society of New York State

Annual Meeting, New York City—April 26, 27, 1942

Headquarters, the Waldorf-Astoria, Le Perroquet Suite

THE thirty-sixth Annual Meeting of the Women's Medical Society of New York State will be held in New York City, April 26 and 27.

There will be a tea at the Waldorf-Astoria, Sunday, April 26, from 4:00 to 6:00 p.m.

The regular annual meeting will be held on Monday morning, April 27.

The program for Monday is as follows: 9:30 a.m.—Registration; 10:00 a.m. to 12:00 Noon—Business Session; 1:00 p.m.—Luncheon.

From 2:00 to 5:00 p.m. the following scientific session has been planned: "Allergies in Children," Gertrude Felshin, M.D., Mt. Sinai Hospital—discussion: Leoni Claman, M.D., Chief of Department of Allergy, New York Infirmary; "Some Clinical Aspects of Endometriosis," Margaret Sturgis, M.D., Clinical Professor of Gynecology, Woman's Medical College, Philadelphia, Pa. (by invitation); "The General Practitioner's Approach and Management of Breast Malig-

nancies," Rieva Rosh, M.D., Bellevue Hospital Radiation Therapy Department—discussion: Dorothy Bell, M.D., Knickerbocker Hospital, and C. Donlon, M.D., of the City Cancer Clinic.

Dinner will be held at the Town Hall Club at 7:00 p.m. The speakers will be: Marguerite P. McCarthy, M.D., President of the Women's Medical Society of New York State; Emily D. Barringer, M.D., President of the American Medical Women's Association; Oliver W. H. Mitchell, M.D., Chairman of the Council Committee on Public Health and Education of the Medical Society of the State of New York—"Postgraduate Medical Education in New York State"; Marion Craig Potter, M.D., Founder of the Society; Margaret Witter Barnard, M.D., Secretary of New York City Nutrition Program—"The Nutrition Program in Civilian Defense."

Winter

weather brings with it another period of throat affections.

Many physicians have found Thantis Lozenges, H. W. & D., to be effective in relieving throat soreness and irritation. They are antiseptic and anesthetic for the mucous membranes of the throat and mouth. Thantis Lozenges contain two active ingredients—Merodicein, H. W. & D., one eighth grain, and Saligenin, H. W. & D., one grain.

They dissolve slowly, permitting prolonged medication; they are convenient and economical.

Thantis Lozenges, H. W. & D., are supplied in vials of twelve lozenges each.

Woman's Auxiliary

To the Medical Society of the State of New York

THE Annual Convention of the Woman's Auxiliary to the Medical Society of the State of New York will be held on April 27-28-29 and 30, 1942, at the Waldorf-Astoria Hotel, New York City. Headquarters will be on the Starlight Roof. All doctors' wives—whether members or not—are urged to attend.

In a few more months the members of the Woman's Auxiliary to the A.M.A. will be arriving in Atlantic City, New Jersey, for their annual convention, June 8-12. Reservations may be made by sending requests to Haddon Hall, Atlantic City.

County News

Columbia. The February luncheon meeting was held at the General Worth Hotel on the twenty-fourth with Mrs. Harry Parker Van Wagenen of Kingston, State Commander of Woman's Field Army for the Control of Cancer, as guest speaker. She told of publicity for this organization being carried on by press, radio, and by films. Mrs. Bowerhan, president of the Columbia County Auxiliary, gave an interesting report on the semiannual meeting of the State Board held at the DeWitt Clinton Hotel in Albany on February 16-17. Many members of the Auxiliary are doing outstanding work in the Red Cross War Relief Drive.

Fulton. Mrs. J. Edward Grant of Northville presided at the February meeting. The group voted to buy a U. S. Defense Bond. After the meeting a question and answer contest was conducted—in which Mrs. Robert Lenz won the prize.

Kings. Kings County in every way seems to keep its programs timely. The February program, with an American Flag gaily flying on the cover, tells of not only a Valentine Tea, but a discussion of "Your Responsibility in Legislation," "Review of a Current Play," a book review of that very best seller, *Keys of the Kingdom*, and also a few highlights on the kind of medical care provided for Abraham Lincoln and George Washington. The March program was all-out St. Patrick. "Your Responsibility in Government and a Bit of Ireland, Too" was not only timely but extremely interesting. The talk on "The Beginning of Medicine in Brooklyn"

arouses our curiosity as to the beginnings of medicine in our own communities.

Nassau. One hundred men and women attended a combined meeting of the medical society and its auxiliary. The speaker was Dr. Richard Brickner, associate professor of neurology at Columbia Medical School. His subject was "Mental Hygiene and Its Use in a World at War." Our Nassau correspondent makes us wish we could have heard this talk which she thinks might well have been entitled "Propaganda and How to Combat It." The Nassau Chapter is cooperating with cancer and tuberculosis committees, is placing *Hygeia* in many schools, and is sending toys to foster homes through the Welfare Department.

Oneida. This chapter sponsored an interesting defense project when 158 men and women were typed as emergency potential blood donors under their auspices. These potential blood donors will only be called in case of major disaster.

Onondaga. The monthly meeting of this chapter was held at Nurses Recreation Hall at the Syracuse General Hospital on Tuesday evening, March 4. Mrs. Robert A. Pond, assisted by Mrs. Beverly Lapham, president and corresponding secretary, respectively, of the Visiting Nurse Association, explained the work of the visiting nurse and illustrated the talk with moving pictures. A dinner is being planned by the auxiliary on Tuesday, April 14, at 6:30 p.m. in the Hotel Syracuse Ballroom. The guest speaker will be Dr. W. W. Bauer, director of the Bureau of Health Education of the A.M.A. His subject will be "Health for Total War."

Schenectady. A delightful Christmas tea was given by this group in December at the home of Mrs. Albert Grusser. The January meeting was a luncheon and bridge held at the Hotel Van Curler. A committee was appointed to sell Defense Bonds among the medical profession. Defense Stamps are to be on sale at each meeting and were given as bridge prizes at the luncheon. The February meeting was held at Sunny View Hospital. Reports on medical legislation were made. Dr. James Blake of Glenridge spoke on "Medical Defense in Schenectady." On March 26-27 a Nutrition Exhibit will be held at the Hotel Van Curler, Schenectady.

"Christ was a perfect man, but Confucius had a better sense of humour."—*The Keys of the Kingdom*, A. J. Cronin (Little, Brown & Co.)

Definition of a jungle gentleman: "A monkey that doesn't monkey around with another monkey's monkey."—*Medical World*

WHERE MEDICAL MEN MEET

No matter where Convention Headquarters may be, medical men convene at the Hotel Shelton for comfort and convenience, to enjoy the many "extras" it offers its guests at no extra charge. A workout in the gym, then a plunge in the famous Shelton Pool prepares them for a strenuous day. Relaxing in the solarium or the library is a pleasant prelude to an enjoyable evening.

TESTING SANO CIGARETTE SMOKE
FOR ITS NICOTINE CONTENT

SANO cigarettes are a safe way and a sure way to reduce your patient's nicotine intake. Sano provide that substantial reduction in nicotine usually necessary to procure definite physiological improvement. With Sano there is no question about the amount of nicotine elimination. With Sano you encounter none of these variable factors involved in methods which merely attempt to extract nicotine from tobacco smoke. With Sano, the nicotine is actually removed from the tobacco itself. Sano guarantees always less than 1% nicotine content. Yet Sano are a delightful and satisfying smoke. Cigarettes • Cigars • Pipe Tobacco

WARNING

Chemical analyses show that pinches of cotton used in cigarette mouth-pieces are entirely ineffective in removing any appreciable amount of nicotine from cigarette smoke.

REVIEWED

Electrocardiography: Including an Atlas of Electrocardiograms. By Louis N. Katz, M.D. Quarto of 580 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$10.

This is an exhaustive treatise on electrocardiography which covers every aspect of the field. It is illustrated by a large number of excellent electrocardiograms which are beautifully reproduced. The explanation accompanying each electrocardiogram is satisfactory. The general text deals with both the theory and practice of electrocardiography. It is a book for the expert rather than the beginner, since the latter might become somewhat confused by the mass of detail presented.

The author introduces a terminology in describing the various complexes and waves consisting mainly of letters—e.g., V, N, etc.—which he thinks facilitates the reading of the tracings. This is not the common method of description, and it seems to the reviewer that it adds to the difficulty of following the text, since the key has to be referred to constantly for a complete understanding of the subject matter.

The author states that if coronary insufficiency has been compensated, the record returns to normal and, if the record is stabilized short of this, there is a residue of coronary insufficiency. It seems doubtful, from a clinical standpoint, that this would be generally agreed upon, since many individuals in whom the record remains abnormal seem to be as well from a functional standpoint as those in whom a normal tracing is ultimately obtained. Indeed, some of the latter still have symptoms of coronary insufficiency.

There are some other minor points on which there might not be universal agreement. Nevertheless, there is no doubt that this is easily one of the best books written on the subject, and it can be highly recommended to those who wish to become familiar with all phases of electrocardiography.

J. HAMILTON CRAWFORD

Exercises in Electrocardiographic Interpretation. By Louis N. Katz, M.D. Quarto of 222 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$5.00.

This work is a supplement to the author's book on electrocardiography. It is designed to give practice in reading electrocardiograms to those who have acquired familiarity with the theory of the subject. In each instance the electrocardiographic findings are correlated with the patient's clinical findings. As is the case in the companion volume, the electrocardiograms are excellent and well reproduced. The book fulfills the purpose for which it is designed in a satisfactory manner.

J. HAMILTON CRAWFORD

Papers of Wade Hampton Frost, M.D. A Contribution to Epidemiological Method. Edited by Kenneth F. Maxey, M.D. Octavo of 628

pages, illustrated. New York, The Commonwealth Fund, 1941. Cloth, \$3.00.

For one quarter of a century Dr. Frost labored unremittingly to develop those basic principles and methods on which the science of epidemiology rests today. By his work and teachings he has contributed greatly toward the establishment of many of the fundamental concepts that have been so instrumental in changing epidemiology into an analytic and productive science. It is most fitting, therefore, that the Commonwealth Fund should publish this book containing twenty of his more important papers.

The introductory preface describes the early life, education, and professional career of Wade Hampton Frost. In the following five sections of the book are grouped, under appropriate headings and explanatory introductions, the papers chosen from his writings as representative of his work and methods. In section 1 are his reports on a typhoid epidemic in Williamson, West Virginia; a milk-borne outbreak of septic sore throat in Baltimore; and certain of his epidemiologic studies on acute poliomyelitis. While all three evidence his masterly analysis of epidemiologic problems, the report on poliomyelitis particularly contributed to enlarge our knowledge concerning the incidence of clinically recognizable and abortive forms of the disease, its dissemination, and the problems of susceptibility and immunity.

The papers in section 2 concerning stream pollution and water purification served the progress of sanitary science by arousing public interest in the dangers of sewage pollution of surface streams and the necessity of surveying watersheds and plants for the purification and distribution of water.

The third section contains his investigations regarding the epidemiology of influenza and the associated respiratory diseases.

Among the articles in section 4 is one on epidemiologic methods which is notable as one of the clearest and most comprehensive descriptions of the philosophy underlying this science. Of the three other papers grouped here, two concern public health methods. They are both practical and constructive and yet idealistic.

The last section is devoted to his more recent publications on tuberculosis, its incidence and control. They are characteristically unique in their approach and logical in their deductions, and no doubt they will prove of great significance in the program of future control of this disease.

JOSEPH C. REGAN

Clinical Immunology, Biotherapy and Chemotherapy in the Diagnosis, Prevention and Treatment of Disease. By John A. Kolmer, M.D., and Louis Tuft, M.D. Octavo of 941 pages, illustrated. Philadelphia, W. B. Saunders Company, 1941. Cloth, \$10.

IN WHOOPING COUGH ELIXIR BROMAURATE

IS A UNIQUE REMEDY OF UNIQUE MERIT

Cuts short the period of illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 or 4 hours.

GOLD PHARMACAL Co., New York

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

[Continued from page 728]

infection, immunity, biotherapy, and chemotherapy are discussed in a clear and highly interesting manner. In the second part these principles are applied to the individual infections and allergic diseases. A detailed description of diagnostic and therapeutic procedures makes the book particularly valuable to the practitioner and clinician, but it will be read with interest also by bacteriologists and immunologists. The critical attitude of the authors raises this textbook above the level of a mere compilation.

U. FRIEDEMANN

Lymphatics, Lymph, and Lymphoid Tissue. Their Physiological and Clinical Significance. By Cecil K. Drinker, M.D., and Joseph M. Yoffey, M.D. Octavo of 406 pages, illustrated. Cambridge, Harvard University Press, 1941. Cloth, \$4.00.

This monograph represents an outstanding contribution to a field where such an authoritative exposition has long been needed. Clearly and concisely written, it should prove valuable as a source of information to those concerned with the practice of medicine as well as to the physiologist, biochemist, and anatomist. Although the title would appear to indicate a restricted discussion, the scope of the book is broad, including as it does a general survey of all factors—anatomic, physiologic, and chemical. Not only is the discussion of current factual matter well presented, but the indications for future investigations are emphasized.

No section of the book should be slighted, but the final chapter on practical considerations is especially significant to the medical reader.

G. B. RAY

Developmental Diagnosis. Normal and Abnormal Child Development. Clinical Methods and Practical Applications. By Arnold Gesell, M.D., and Catherine S. Amatruda, M.D. Octavo of 447 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$6.50.

Dr. Gesell and his coworkers have spent years in the study of developmental examinations of infants and young children, and they have written extensively on the subject. This volume is a consummation of their past work.

The first chapter deals with the nature of behavior and of mental growth. In the following chapters illustrations of tests used in diagnosis and the proper integration of these tests into the various age levels are presented in a fascinating and basic manner.

The necessity of a thorough physical check-up, as well as the determination of the functional maturity of the nervous system, is particularly necessary in the infant and preschool child. It is at this early age that thoroughness of such examination is often neglected. Young children often enjoy the methods employed in making a developmental examination. You are putting yourself on an equal basis or on the same age level as the child. Thus, confidence is established and, when the more terrifying aspects of the physical examination take place—e.g., looking at the ear drums or throat—cooperation is attained.

Part 2 is concerned with the diagnosis of the abnormal child in terms of the previously described normal procedures. One chapter deals with child adoption; all physicians who are interested in this subject should read it.

In Part 3 the protection of early child development is discussed. The responsibility of the physician is grave. He not only must make a proper diagnosis but must be prepared to impart such a diagnosis. Hence, proper guidance must be the keynote in each individual situation, whether the child be normal or defective.

The vistas opened in this volume will add new fields of thought to the physician's ever increasing armamentarium of diagnostic methods.

THURMAN B. GIVAN

Diseases of the Respiratory Tract. By Jacob Segal, M.D. (Oxford Medical Outline Series.) Octavo of 172 pages. New York, Oxford University Press, 1941. Cloth, \$2.00.

Dr. Segal has accomplished the extraordinary feat of making an excellent compendium of the vast literature on diseases of the respiratory tract. His judgment in evaluating the space that each topic must command has been beyond cavi. It is rare to find this delicate task of balance and selection so admirably done.

As might be expected from the author of a standard work on tuberculosis, this field is expertly treated. However, no less can be said of other sections of this outline. As might be expected in any work of this general description, there will always be differences of opinion on questions of emphasis. For example, the reviewer would have wished for a more urgent warning against the use of morphine in bronchial asthma and a reiteration of the commonly accepted clinical observation that pulmonary embolism may be present without either symptoms or signs. To wait for classic signs is to delay diagnosis in many cases. However, these criticisms are minor indeed when the accuracy and soundness of the outline as a whole are considered.

MILTON PLOTZ

Standard Radiographic Positions. By Nancy Davies, M.S.R., and Ursel Isenburg, M.S.R. Octavo of 136 pages, illustrated. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$2.00.

The necessity of standard radiographic technic has long been stressed by all radiologists worthy of the name. The authors have successfully endeavored to describe and illustrate these standard positions by plain, concise description and excellent illustrations, so that radiographers (x-ray technicians), by following directions, can produce and reproduce radiograms of such constancy that correct interpretation is made possible. As trained technicians they realize that none can be considered efficient without employing standard exposures, and to that end they have succeeded admirably.

A timely subject is the special chapter devoted to the localization of foreign bodies. A modification of the J. Mackenzie Davidson technic is described in full and, if followed carefully, it should prove highly satisfactory.

TRAVEL MEDICINE

No Army Secret—this achievement!

WAR brings out the best in nations as well as the worst. The movement of 600,000 troops, especially by a nation supposedly still woefully unprepared and indifferent to the fact of being at war, in a matter of two weeks and two days must surprise even the tacticians of the blitzkrieg.

In the sixteen days preceding Christmas, this large army was transported by our railroads over more than 200,000 miles of track. Seventy-five per cent of the soldiers actually had sleeping accommodations, and the balance traveled in comfortable day coaches—not a one in box car as in the last war. The whole huge task was accomplished with the loss of only one soldier, a colored cook killed in a collision.

In the *United States News*, David Lawrence, the editor, described this colossal job. "It was a mammoth task in planning and administration," Mr. Lawrence remarked. "The Association of American Railroads, acting for all the railroads, sent out orders and worked on a twenty-four hour basis, pooling locomotives and cars and fitting in here and there special trains irrespective of whether the load was enough for a train. It was important to

move the troops and get them to their destination, and the wires of the railroads were so crowded that at times all forms of communication from telephone to relayed messages through various channels were utilized.

"What makes the performance of the American railroads even more remarkable is that along with the troops traveled freight cars which bore their supplies and equipment. The soldiers went fully equipped—ready for action. To carry this equipment—tanks, guns, and ammunition—was a tremendous transportation job in itself.

"How was such a large number fed? The army carried its own food kitchens which were set up in baggage or freight cars. It took an immense amount of planning, but everything went off without a hitch. The troops were moved—some 600,000 of them—and they arrived at appointed places on a schedule that would have amazed Herr Hitler. For it is doubtful whether he has ever moved so many troops so fast as America did just before Christmas."

[Continued from page 730]

This book is of great value to those young men and women who would become x-ray technicians in the present war, as well as to those physicians who would employ the x-ray in their general practice.

MILTON G. WASCH

Principles of Microbiology. By Francis E. Colien, M.S., and Ethel J. Odegard, R.N. Octavo of 444 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$3.00.

This is an excellent comprehensive work on microbiology intended for the nursing science. To quote from the preface: "The subject matter has been arranged . . . to meet the excellent recommendation of the Committee on Education of the National League of Nursing Education." The work is divided into seven parts. Part 1 discusses historical matters, microscope biology, cultivation, and methods of studying microorganisms; Part 2, destruction of organisms; Part 3, classification of microbiology and nursing; Part 4, infection and immunity; Part 5, pathogenic organisms; Part 6, microbiology in relation to water and milk; Part 7, an appendix with chapters on culture mediums, laboratory exercises and demonstrations, and a glossary.

The book is profusely and adequately illustrated and a satisfactory bibliography is presented. The book should find an important use as a textbook of microbiology for nurses.

MAX LEDERER

Pathology of the Oral Cavity. By Lester R. Cahn, D.D.S. Octavo of 240 pages, illustrated. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$5.50.

In this work the author presents a concise résumé of the principles of inflammation with photomicrographs of blood changes, which should be of interest to the practitioner.

The chapter on Diseases of the Hard Structures of the Teeth contains nothing new. The discussion of periapical pathology is well worthwhile and shows many changes of surrounding tissue and apices from a new aspect.

Osteomyelitis and necrotic sequestrums can be definitely separated, particularly in cases that have been treated by deep roentgen therapy. Surgery in the oral cavity should be postponed for at least one year subsequent to the last treatment of roentgen therapy. Dr. Cahn stresses this point in the chapter on Tumors of the Jaw Bones.

The cross section of tumors of the oral cavity covers a field with which the general practitioner should acquaint himself more thoroughly. It is well presented, particularly the case history of the adamantinoma. This type of tumor is formed from epithelium of the enamel organ type and generally forms during the age of tooth formation. It is more prevalent in women than in men, particularly of the Negro race, and is not considered malignant but, as Dr. Cahn states, recurs frequently after operation.

There is an interesting chapter on oral manifestation due to lack of proper vitamin intake. This being a comparatively new field and an important one, it should be received with in-

terest. Many of the forms of stomatitis are attributable to avitaminosis.

It was an interesting privilege to review Dr. Cahn's book.

G. B. JOHNSON

Obstetrics. By Hervey C. Williamson, M.D., and George Schaefer, M.D. (Oxford Medical Outline Series.) Octavo of 113 pages. New York, Oxford University Press, 1941. Cloth, \$2.00.

The book is a brief outline of the fundamental principles of obstetrics and their practical application. The symptoms, physical signs, differential diagnosis, and treatment of obstetric complications are clearly written. Important new advances in chemotherapy and x-ray are included. It should be a valuable adjunct in the study of obstetrics for medical students.

ALEXANDER H. ROSENTHAL

The New International Clinics. Original Contributions; Clinics; and Evaluated Reviews of Current Advances in the Medical Arts. Edited by George M. Piersol, M.D. Volume III, New Series Four. (September.) Octavo of 300 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1941. Cloth, \$3.00.

The outstanding feature of this issue is Cantarow's usual thorough and instructive review of recent advances in clinical biochemistry. More than a hundred pages are devoted to a series of clinics from Washington University, St. Louis. Barr's paper on obesity and Findley's paper on acidosis in hypertension are conspicuously thought-provoking. The latter's article brings to mind the important contribution of Marzullo on acidosis in uremia. It is not impossible that some common factor in pathogenesis may be found.

MILTON PLOTZ

The 1941 Year Book of Public Health. Edited by J. C. Geiger, M.D. Duodecimo of 544 pages. Chicago, Year Book Publishers, 1941. Cloth, \$3.00.

This annual review of public health matters has many chapters that concern the private physician in his practice. Of particular interest are the discussions on communicable diseases. The comments on influenza, common colds, the exanthemas, and the like are presented in a terse, time-saving manner. Tuberculosis, poliomyelitis, and the venereal diseases are treated more fully. Other chapters on health education, industrial hygiene and mental hygiene present information of everyday interest to the general practitioner.

ALFRED E. SHIPLEY

Necropsy. A Guide for Students of Anatomic Pathology. By Béla Halpert, M.D. Duodecimo of 75 pages. St. Louis, C. V. Mosby Company, 1941. Cloth, \$1.50.

The text presents a detailed description of how an autopsy should be performed. The various organs and their relation to adjoining structures are examined in situ. The method for their removal and examination of each individual organ is fully described. It is a valuable guide to the important points to be observed during a necropsy.

EDWARD H. NIDISH

THE MAPLES INC., ROCKVILLE CENTRE, L. I.

A sanitarium especially for invalids, convalescents, chronic patients, post-operative, special diets, and body building. Six acres of landscaped lawns. Five buildings (two devoted exclusively to private rooms). Resident Physician. Rates \$18 to \$35 Weekly

 Telephone: Kingsbridge 9-8440

LIFE IN BOMB SHELTERS

Life must change a little when a group of people are thrown together in an emergency. It is remarkable how quickly they can become adjusted to tolerating others, where ordinarily they would not "mix."

In chalk caves near London, many people have found refuge, have overcome great difficulties of "life beneath the surface," and have even managed to install many comforts.

One of the partners of the chalk mines has planned all the sanitation, installation of electricity, canteens, and Red Cross posts. With the help of others an orderly communal life has been organized, with various tasks of fire-watching, wardens, cleaners, sanitary squad, marshalls, etc. The motley ramshackle collection of beds that had been dragged in by their owners were banished and orderly rows of iron bunks have been furnished by the Government.

As it is a private shelter, curtains are allowed and each occupant can withdraw to the amount of privacy these many colored bits of cloth provide.

Ten cents a week (a sixpence) is charged adults (children are free) and this helps pay for the electricity and most of the upkeep. An ex-prize fighter guards the entrance and all must be in by 9:30 P.M. The tenants pour from trains and communal lorries down into the underworld, and as early as 4:00 A.M. in the morning flood out again, the men to their work and the women and children to some sort of an outside home.

TERRACE HOUSE for ALCOHOLISM

A private sanatorium offering a specific treatment for alcoholism, formulated to relieve the craving for alcohol and with re-education working toward permanent abstinence. Homelike surroundings. Competent medical and nursing care. 16 miles from Buffalo.

NATIONAL COMPLEX B₁

If a patient asked you the following questions, how would you answer them?

1. Is a well-rounded diet the best way to insure a proper intake of vitamins?
2. What do you think of the advisability of taking vitamins in capsules or pill form *without the advice of a physician?*
3. Could any conceivable harm result from taking them on your own?
4. How about their effect on a hangover?

To physicians, generally, both answers and questions must appear rather elementary. But not so to the laymen who more often than not get the wrong answers the wrong way.

A housewife, writing for the *Junior League* magazine, interviewed five distinguished medical men to get the right answers to the riddle of vitamins the right way. She asked the same four questions of each of the authorities and, strangely to her it appears, obtained in general the same opinion from them all. According to the lady, "despite the difference in their work, age, personality and methods of expressing themselves," all said essentially the same thing.

All agreed that there is undeniably an overemphasis on vitamins . . . that it isn't a good idea to take additional vitamins without competent advice . . . and that a well-balanced meal is the best means to accomplish the common objective.

"Don't waste your money" seemed to be the general admonition. "Don't play with vitamins," cautioned one physician. While another—"wished that all the excess synthetic vitamins consumed by those who didn't need them could be sent somewhere where they would do real good in combating deficiencies."

All five medical men interviewed assured this woman that packaged vitamins had their place and their functions—and a valuable one at that—but were inclined to

be widely mis-used and so,

the lady learned that a vitamin B pill will have no effect on that morning after feeling, although employed in some extent in treating certain cases of chronic alcoholism.

The result of the interviews may be summed up in the woman's own reaction to the answers she received. "It certainly is understandable," she wrote, "perhaps it is inevitable, that with the build-up and publicity attendant upon the real service vitamins have done in combating deficiencies, they (the commercializers) should have capitalized on it, and tapped the great extra market that exists in fad-loving America, and that the widespread use of commercial vitamins should have gotten off to such a flying start. Rather than get on the bandwagon, I would prefer to accept the composite opinion of these doctors who have no commercial axe to grind, and whose whole lives are concerned with the problem of making people healthier."

Last Call for the Annual Meeting

In the April 1 issue we called your attention editorially to some of the important features of the forthcoming one hundred and thirty-sixth annual meeting. You will note from the entire program, published in that issue, that the predominant emphasis is upon military medicine, but that the needs of civilian care have not been overlooked. This year, no physician in the state of New York who can possibly attend should fail to seize the opportunity, both as a duty to himself and as a benefit to his patients.

Grave changes in the pattern of life are in the making. By the time you read this, all male citizens between the ages of 20 and 45 will have registered, and by the time you arrive at the annual meeting, April 27-30, in New York City, all citizens up to the age of 65 will have registered under Selective Service (see notice on page 821), and, we hope, will have filled out their new registration blanks for the Procurement and Assignment Service.

It will, therefore, be with clear consciences (income tax returns for this year being a matter of history) and with lighter hearts and pocketbooks that the profession of the Empire State will gather

at the Waldorf-Astoria Hotel, blackout or no blackout.

The banquet on the evening of April 28 will be noteworthy. Under the suave and skillful toastmastership of Dr. Chas. Gordon Heyd, former president of the A.M.A. and of the Medical Society of the State of New York, you will hear addresses by Dr. Frank H. Lahey, president of the A.M.A., and many other distinguished guests. Acceptances by some must necessarily be tentative because of their war duties, but it seems reasonably certain that Major General Irving J. Phillipson, commanding general, Second Corps Area; Brigadier General Lewis B. Hershey, national director of Selective Service; and Major General James C. Magee, surgeon general of the U. S. Army, will speak.

Our own president, Colonel Samuel J. Kopetzky, medical director, Selective Service, New York City, and chairman of the New York State Committee of the Procurement and Assignment Service, will give his presidential address.

The invocation will be spoken by Rabbi Leo Jung, and there will be music by the Doctors' Orchestra. Do not fail to secure your banquet tickets early (see page 760).

This War Is Different

Nearly all of us are old enough to remember the first World War and can realize how different this one is, not only in a technical sense but also in its different effect upon the civilian population. Remember that while in the last war we trained an immense army and sent half of it abroad, we sent, with few exceptions, only the men and light equipment—no artillery, no tanks, no airplanes. And the men and light equipment were sent for the most part in British ships. This meant that on the production side we did but little. There were few priorities, little or no turning of industries completely over to war needs. Business was as usual, and more than usual; we had a wartime boom. People had lots of money and there were lots of things to buy—at boom prices, of course.

The cost of the former war was largely met by Liberty Loans, as they were called. These loans, four of them in all, were launched in big drives, with teams and quotas and mass meetings—intensive campaigns lasting but a short time. Great enthusiasm was thus created, and people bought bonds in large amounts during a campaign. They drew their money from savings banks or depleted their drawing accounts. Many, in the fever of the moment, bought more than they could manage to pay for, and had to sell again in a short time, taking a loss and damaging the credit of the country.

In this war we are also raising and equipping immense armies, but we are doing much more. We are making planes and guns for them, tanks, and all sorts of motorized equipment. We are building for ourselves a two-ocean navy, quantities of transports, and cargo vessels. We are doing even more; we are making these things for our allies as well, and we are proud to be called the "arsenal of the democracies."

This tremendous effort has necessitated the transformation of half our industrial productivity into war work, and this in turn means that only half as many

things that we usually buy are being manufactured for us. Add to this some classes of goods for the production of which raw materials (as rubber) can no longer be obtained, and we have the picture of a famine of goods in the midst of plenitude of industrial activity.

There is a great difference, also, in the financing of this war. There is much heavier taxation; and the bond issues, instead of being substantially alike but issued at different, specified times, are essentially unlike and are issued continuously and concurrently. The object of this new method is to persuade us to invest as we can, each week or month, from our current receipts. Taking our savings from savings banks for this purpose *does not help*, for the savings banks must sell government securities in order to pay us our money.

There are great advantages in this method of purchasing bonds regularly, and in as great amounts as our earnings will permit. These advantages accrue both to the nation and to ourselves. Our country is provided with the steady revenue it needs for its war production, and the danger of a runaway inflation will be avoided—an inflation which would not only interfere with the financing of the war, but would work a great hardship on all of us. Such an inflation will yet come if too many people try to buy things with their money, in competition with one another and with the government, when there are not enough things to go around.

Among the advantages of bond purchases to ourselves, individually, is, first, the deep satisfaction that comes from self-discipline and self-sacrifice. Ours is the satisfaction of knowing that we are doing our part to the best of our ability, that we are making this sacrifice at the same time that men in the fighting forces are making their great sacrifice.

The second advantage is in the sphere of prudence, or foresight. We do not know what will happen after the war is

over and the victory won, but the predictions are that there will be bad times until the world readjusts to peacetime production again. Now is the time, when money is plentiful, to lay by something for this future depression. As we buy the bonds regularly now, they will mature regularly then. And, if we do not voluntarily make the sacrifice now, when it will help our country, we shall have to make it then—with no advantage to anyone, and least of all to ourselves.

The third advantage is a matter of plain horse sense. There are many things that we ordinarily buy from time to time that

are not available now. We shall need them when we can get them. There are of course many things that we can get now, but the price is too high and quality none too sure, because of priorities and deficiencies of materials. We shall be wiser to wait, if we possibly can, until the war is over, to make these purchases.

And if we now put our money into savings bonds instead, then, when the war is over and all these things again become available at normal prices and in standard quality, we shall have the means to buy them.

New Physical Standards for the Army

For the information and guidance of our members who will be asked about the Army's new physical standards of acceptance for *limited military duty for officers*, we republish the following regulations, detailed in an order issued by the surgeon general of the Army, as published in the *J.A.M.A.* for March 28:

A man who has lost one leg, provided it is below the junction of the middle and lower thirds of the thigh and has been replaced with a satisfactory artificial one, may now be considered acceptable for limited service as an officer of the supply arms and services of the Army.

A wide variety of physical defects which heretofore have stood as a barrier to service in the Army is listed in the order as being considered acceptable for limited service with waiver, and in addition there are enumerated a number of conditions on which waiver may be accepted for general military service.

The order is divided into three sections. The first concerns those defects considered acceptable for limited service. These include:

Overweight to 25 per cent above average weight for age and height, and underweight to 15 per cent below ideal weight, provided chest x-ray examination is negative for disease changes of the lungs and other chronic disease is carefully excluded.

Vision 20/400 in each eye corrected with glasses in possession of the examinee to 20/20

in one eye and to at least 20/40 in the other, provided no organic disease of either eye exists.

Blindness, or vision below 20/400, in one eye, with vision 20/100 corrected with glasses in possession of the examinee to 20/20 in the other, provided there is no organic disease in the better eye and no history of cataract or other disease in the more defective eye which might be expected to involve the better one, and provided that, in case of the absence of an eye, the individual is fitted with a satisfactory artificial one.

Complete color blindness.

Hearing 5/20 in each ear for low conversational voice, or complete deafness in one ear with hearing 10/20 or better in the other, provided the defect is not due to active inflammatory disease and is stationary in character.

Loss of one hand, forearm, or lower extremity, provided the lost member is replaced with a satisfactory artificial one.

Flatfoot, excessive curvature of the sole of the foot, or a clubfoot in which the individual walks on the toes due to elevation of the heel by contraction of the Achilles tendon, provided the condition is asymptomatic and does not interfere with normal locomotion.

Joints fixed or limited in motion, provided the condition is the result of injury and is non-symptomatic.

History of gastric or duodenal ulcer, provided there is a trustworthy history of freedom from activity during the preceding five years and provided an x-ray film of the gastrointestinal tract at the time of examination is negative.

The second section of the order concerns conditions considered unacceptable for any service, and include:

History of malignant disease within the preceding five years; syphilis, except when ade-

quately treated; instability of the major joints; diabetes of any degree; history of any psychosis.

The third section concerns those conditions which may be recommended for general military service with waiver. They include:

Confirmed positive serologic tests for syphilis with no clinical evidence of the disease, with reliable histories of treatment for the disease, and provided that a negative spinal fluid since infection and treatment has been reported from a trustworthy source.

Overweight to 20 per cent above average weight for age and height, and underweight to 12.5 per cent below ideal weight, provided x-ray of the chest is negative for tuberculosis and other chronic disease is carefully excluded.

Insufficient incisor or masticating teeth, provided the mouth is free from extensive infectious processes and satisfactory dentures are worn.

Let no man feel that he will not be able to play a useful part in this, our first total conflict. There will be a place for him somewhere.

The New England Journal of Medicine

In a letter to the *New York Times* of March 25, 1942, Dr. Henry R. Viets of Boston, quoting an editorial in that paper, of March 22, entitled "A Yale Genealogy," says:

It would be interesting to trace the lives and usually early deaths of magazines that have taken the name of New England. . . . One stalwart in that line is the *New England Journal of Medicine*, the first journal of medicine in this country, if not in the world, which has continued, despite changes in form and of name, in uninterrupted existence since 1812. The name "New England" was held from 1812 to 1828, when the magazine became the *Boston Medical and Surgical Journal*. In 1928 the name again became *New England Journal of Medicine*.

We are beholden to Dr. Viets for this interesting information about this stalwart publication. Always an appreciative admirer of the contents of the *New England Journal of Medicine*, the NEW YORK STATE JOURNAL OF MEDICINE now finds itself viewing with reverence this additional, and until now to us unknown,

attribute of great age of our northerly sister. We are content to have the respectable, even genteel, name of New England carried forward from generation to generation by such a worthy vessel. The episode of the Boston wild oats, from 1828 to 1928, has already been forgiven, and will soon be forgotten. In another century, not one of us now living will remember it.

In the light of this new learning from the pen of Dr. Henry Viets, historian, we shall henceforth turn the pages of our copies of the *New England Journal of Medicine* gently, with great delicacy. And as they rustle under our disturbing touch, they will remind us of the glories of her youth, the crinolines of Dolly Madison, the exploits of Commodore Perry and Captain Lawrence, and of the *Constitution* and the *Guerriere*, *Old Ironsides*, Tecumseh's Conspiracy, and Har- rison at Tippecanoe.

Reservations for the Annual Banquet

. are now being made. Requests should be sent to Alfred M. Hellman, M.D., chairman, Banquet Committee, Medical Society of the State of New York, 292 Madison Avenue, New York City. Tickets are \$5.00, plus 14 cents tax. Checks should be made out to the Medical Society of the State of New York.

The banquet will be held in the Waldorf-Astoria Hotel on Tuesday, April 28, at 7:00 p.m.—a *must* occasion for everybody.

THE CONSERVATION OF RENAL TISSUE

JOHN E. HESLIN, M.D., Albany, New York

THE presentation of a paper upon this subject before a group interested in urology should be prefaced with an apology, for urology itself was founded upon the postulate of conservation of renal tissue. In applying the principles of urology, we unconsciously aim at such conservation.

However, with the advent of chemotherapy and its miraculous relief of symptoms, even in the presence of calculi and obstruction, the danger of neglected pathology increases, and we must remind ourselves and others that these potential destroyers of kidney function must be recognized and relieved.

Frank Hinman,¹ in discussing urinary tract infections and the use of modern urinary antiseptics, makes the following statement, which seems apropos in the present discussion:

"The dangers of procrastination grow greater and greater as urinary antiseptics grow better and better.

"Why all the excitement when the ingestion of a few pills clears the urine. . . . The wise physician, knowing that most urinary infections are secondary, will suspect other trouble even when pills are successful. He will not be satisfied until all the findings, gradually collected step by step by means of the preceding studies, demonstrate suspected pathologic changes or prove that his suspicions were false."

The wide use of intravenous urography makes the recognition of many lesions much more simple and opens up a wide field of usefulness in this subject.

To conserve renal tissue implies conservation of renal function and, although we are well endowed with this tissue, the newer physiology of the kidney and the possible relation of unilateral renal disease to hypertension and other diseases reveal to us that we may urgently need this reserve in later years.

As evidence of the possibilities of the result of kidney damage, the *Cumulative Index of the American Medical Association* for 1940 lists 158 references under "Physiology of the Kidney" with all types of experimental work. We are apt to consider the filtration property of the kidney as its greatest function, but a review of this list and the known functions of

the kidney impress one with the importance of these vital organs.

We are dealing with a finely adjusted mechanism and with its reserve and adaptability; it is apparently able to cope with great emergencies and long-continued embarrassment. We learn each day of its great restorative powers, but we do not yet know the part an even slightly lowered function may be playing in diseased states.

Since we are told that slightly diminished function in one kidney may be a clue to the underlying cause of hypertension, is it too much to suspect that further studies will reveal a close relationship of reduced function to now little understood diseases? Only yesterday, we were referring cases of hypertension from our offices to internists and, today, they are referring them back to us. Who can say but what tomorrow our field of usefulness in urology may be further widened in the investigation of obscure diseases?

The physiology of the kidney has been a point of discussion for years and, today, there is no general agreement among physiologists as to the manner in which it functions. Time does not permit a full review of the work of Bellini, Ludwig, Bowman, and Heindenbain or that of Cushny, who in 1917 advanced his "modern theory" of renal function. He maintained that the urine, filtered through the glomerulus, contained everything carried by the blood except protein. Upon reaching the tubule, the selective and absorption properties allowed necessary or "threshold" substances to be absorbed, while material such as ureas and other end products, not needed, or "nonthreshold" substances were excreted.

A. N. Richards² and his colleagues at the University of Pennsylvania have proved since that time the existence of glomerular filtration and tubular absorption.

The kidney, then, not only filters from the blood stream substances not needed but must protect the body against loss of substances necessary for its maintenance, such as water, inorganic bases, and diffusible foodstuffs.

Lowsley and Kirwin³ quote Richards' summation of the processes of filtration, reabsorption, and secretion as follows:

"Evidence. . . seems not only to justify but to necessitate belief that the first function of the kidney is to separate a filtrate from blood

¹Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 20, 1941.

quately treated; instability of the major joints; diabetes of any degree; history of any psychosis.

The third section concerns those conditions which may be recommended for general military service with waiver. They include:

Confirmed positive serologic tests for syphilis with no clinical evidence of the disease, with reliable histories of treatment for the disease, and provided that a negative spinal fluid since infection and treatment has been reported from a trustworthy source.

Overweight to 20 per cent above average weight for age and height, and underweight to 12.5 per cent below ideal weight, provided x-ray of the chest is negative for tuberculosis and other chronic disease is carefully excluded.

Insufficient incisor or masticating teeth, provided the mouth is free from extensive infectious processes and satisfactory dentures are worn.

Let no man feel that he will not be able to play a useful part in this, our first total conflict. There will be a place for him somewhere.

prevention by knowledge of its possible development; its early recognition and proper treatment not only conserves renal tissue but may act as a prophylactic measure in hypertensive disease.

Infection more marked in the pelvis produces its destructive effects through obstruction, resulting dilation and poor drainage, or by primary obstructive lesions. Braasch is credited as the first to point out that dilation of the pelvis and calices can take place as a result of inflammation in the absence of obstruction. Compression atrophy of the parenchyma results; there is progressive loss of vital tissue and continued infection or stone formation, frequently leading to total loss of the organ.

The ureter may be the seat of changes following infection or stone and play a leading role in pathologic change. Instrumental dilatation following removal of a long-standing impacted ureteral stone may well be an important prophylactic measure.

To be sure, all cases of infection of the upper part of the urinary tract do not progress in this manner but, if we are to protect our patients' welfare, we must approach infection with these changes in mind and continue, in many cases, not only our therapy, our instrumental and our operative procedures, but by frequent urographic and bacteriologic studies note the physical and bacterial status of the upper part of the urinary tract.

Renal Calculi.—Although we see an occasional case of renal stone going on for years without symptoms or changes in the kidney, it is extremely rare. The presence of stone jeopardizes kidney parenchyma by production of obstruction, infection, and multiplicity.

Obstruction and changes in a calix harboring a stone is of utmost importance in the medical or surgical treatment. It is difficult to completely eradicate associated infection and further stone formation of fine sandlike particles making their complete removal impossible. The excision of a calix, as suggested by Twinum,⁴ is a most conservative procedure, and possible resection of the entire pole when indicated would be a more conservative procedure eventually than simple pyelolithotomy or nephrolithotomy.

The free stone in the pelvis is almost certain to cause symptoms and, as it occludes the ureteropelvic junction, increasing obstruction, with dilatation of the calices and infection, makes later nephrectomy a necessity.

In this type of case, secondary changes at

the ureteropelvic junction may have advanced to a point where simple removal of the stone is not enough, the remaining obstruction contributing to further dilation, residual infection, and recurrent stone formation. Plastic procedures to prevent this serious end result should be carried out more often than at the present time. Any series of cases of stone recurrence will show that in a high percentage of cases nephrectomy is carried out at the time of the second operation.

Because of this great loss of kidney tissue in stone recurrence, everything must be done for its prevention. Not only should we carry out the regimen of stone analysis, regulation of the urine pH by diet or medication, correction of a vitamin deficiency, removal of infection, but at the time of operation we should make certain that we have left no small fragments and have carried out all necessary surgical procedures to insure normal functioning of kidney drainage. These surgical procedures may require a plastic procedure or possibly a simple nephropexy.

The statistics of many clinics show a reduction in the percentage of recurrence of stone from 40 to 50 per cent to under 5 per cent—a striking example of urology's contribution to renal conservation.

Because of malposition or production of obstruction, anomalies of the upper part of the urinary tract are frequently proved to be the primary cause of destructive urologic lesions in children and adults. Their discovery warrants surgical correction, or at least observation, to control the progress of kidney damage. Intravenous urography here is of great value, and this investigation of all pyurias in children not responding to medication will reveal a large number of these anomalies.

Hydronephrosis due to aberrant vessels is an excellent example of the value of early diagnosis where the ligation of a vessel or a plastic operation upon the pelvis where the vessel cannot be sacrificed will save a kidney.

The horseshoe kidney will usually become infected with development of stone formation and, upon discovery, serious consideration should be given its correction by symphysiotomy and nephropexy.

Improved surgical procedures have made it possible to perform heminephrectomy when one portion of a double kidney is involved, thus saving the remaining portion for a possibly much-needed service later.

Priestly and others have advocated the removal of large branched calculi. We all can

in volume so enormous as to contain all the waste products of metabolism and the unneeded salts and water. Necessary as this function is, were it uncorrected death from dehydration and loss of bases would inevitably and promptly ensue.

"Corrective processes of reabsorption by which escape of water, salts, and diffusible nutrients essential for survival is prevented are distributed among the different segments of the tubules. These are the processes which are finely adjusted to serve the varying excretory requirements of the body as a whole. By chemical rather than by nervous messages, tubule cells are informed of small changes in the composition of the blood; by mechanisms, as yet beyond description, their response is so discriminately effective that the narrow optional ranges of its variations is preserved.

"Tubule cells also secrete. The demonstration of this capacity in the mammalian kidney is as yet limited largely to the excretion of substances which are not normal products of metabolism or constituents of the normal bladder. Its mechanism is wholly obscure. It may be that this capacity is more important than present knowledge indicates. If so, revisions of current belief will be necessary."

The protection or conservation of renal tissue from a strictly medical standpoint has to do with the nephritides and changes associated with arteriosclerotic disease. The causes of these conditions are little understood; hence, measures to prevent are more difficult to outline. They are most important, but the basis of this paper is a discussion of the renal damage brought about by urologic conditions. Practically all urologic disease, directly or indirectly, influences kidney function.

Urethral strictures are a frequent cause of secondary changes in the urethra, the bladder, ureters, pelves, calices, and parenchyma. Strictures of small caliber are probably never cured and must have periodic dilatation through the patient's life to prevent damage of the upper part of the urinary tract. With the use of the newer drugs in the treatment of gonorrhea in the male, we are seeing a fewer number of cases of urethral stricture. This does not mean that they do not occur, although my impression is that their frequency is greatly lessened. It is doubtful if many cases of gonorrheal infection are now carefully checked for stricture or prostatitis. Let us hope that these drugs, so widely used and so efficient, will not thus aid in residual local

pathology and more serious secondary complications. More important, possibly, is the well-developed urethral stricture brought to our attention by the persistent mucoid discharge. These so often respond to modern internal medication that the underlying condition is never discovered. It is in cases of infection with underlying pathology where chemotherapy may prove to be an accomplice in the neglect of this pathology.

Prostatic surgery was one of the earliest procedures to conserve renal tissue. The recognition of the fact that renal damage, resulting from residual urine, accounted for the high mortality in this type of surgery gave urologic surgery its first great advance. With the advent of transurethral resection, with its lessened risk and economic drain, we are seeing these patients at an earlier stage before the upper part of the urinary tract has undergone change from long-standing residual urine.

The general practitioner who sees these patients in the early prostatic age must consider the early obstructive case with slight symptoms but definite residual urine and refer him before these changes have taken place.

With the greatly reduced morbidity and mortality in all types of prostatic operations, we owe to these men who place their future health in our hands an opportunity to avail themselves of procedures to insure their health and comfort in later years. When marked symptoms with infection and retention have taken place, not only is the risk of operation greater but the end result, although giving a satisfactory functional result, cannot always remedy the badly damaged kidneys.

Urinary tract infection is probably the most frequent disease affecting these organs. Acute infections are of less importance in the subject under discussion, although acute pyelonephritis and carbuncle may be destructive. Associated obstructive lesions and the development of secondary changes along with chronicity make it urgent that procedures—prophylactic and curative, both medical and surgical—be carried out completely to prevent destructive changes.

Chronic infection of the kidney may have changes more marked in the parenchyma or in the pelvis, and their mode of destruction differs. When the parenchyma is involved, the changes may be similar to those of chronic nephritis. Fibrosis may be marked with secondary atrophy and great loss of renal parenchyma. This phase of renal infection—chronic pyelonephritis—may be associated with the production of hypertension and its

relationship of long-standing chronic infection of the kidney with some cases of hypertension.

Many patients with chronic urinary infections are treated without thorough investigation, and only when serious damage has resulted do they seek the advice of the urologist. On the other hand, many urologists will permit a partial ureteropelvic obstruction to go untreated until the kidney has been destroyed beyond saving. It is not uncommon to see a patient with symptoms referable to the genital tract treated for many months or even years, when the cause of his continued genital infection was a unilateral infected kidney.

Prostatism in its early stages is not difficult to correct by operation and the resulting conservation of renal tissue makes it a wise procedure. Yet, urologists often advise patients to "wait" if their "symptoms" are not severe. Excretory urograms often show early evidence of delayed emptying of the kidneys in prostatism; yet, either such x-rays are misinterpreted or the urologist may unwisely wait for gross evidence of renal damage before surgical intervention is considered. It is my impression that many of the public wish us to protect their health rather than wait until their conditions become serious.

It is a simple surgical procedure to remove a destroyed kidney. It requires far greater intelligence to have a thorough conception of the origin and progression of a disease and the ability to diagnose such a disease early, remove the cause, and prevent the kidney from being destroyed. We are rightly to be considered inadequate urologists if we are unable to diagnose disease of the urogenital tract early, anticipate its progression, and institute active treatment with an aim toward preventing progressive destruction.

Dr. F. J. Parmenter, *Buffalo, New York*—Dr. Heslin is to be commended for calling our attention to the great importance of conserving renal tissue. It is an old story which the urologists have been preaching for years, and cannot be repeated too often.

Dr. Heslin stresses the importance of not allowing the physician to be lulled into a false sense of security by the not infrequently spectacular results of our newer antiseptics that may temporarily relieve the patient but not remove the underlying pathology that continues its insidious work of destruction.

The trend of modern urology is the conservation of renal tissue, which is well illustrated by the many forms of therapy which improved methods of diagnosis have placed in the hands of the urologists. As is well known, stasis causes back pressure and infection, which are the two combinations that are responsible for the damage in the vast majority of instances. To overcome them, early diagnosis with adequate drainage, removal of the causative pathology, to-

gether with the elimination of the infection, are all-important.

Hemholtz in a recent address pointed out the necessity of proving by culture, at least four days after stopping antiseptic therapy, that infection has been eradicated, instead of relying upon a clear urine with absence of pus cells.

Subacute infections and toxic products from remote foci are responsible in my opinion for many of the late renal changes grouped under the term "Bright's disease." In not a few patients a history of recurring attacks of pyelonephritis, perhaps dating from childhood or pregnancy, can be found by taking a careful history. This, with the presence of bacteria in the urine and the other renal changes found at the examination, makes it only too clear that infection is still present and is the causative factor.

The ureteral catheter has proved to be most helpful in draining an infected kidney if it can be passed above the obstruction, thus giving the kidney a chance to recover and permit some form of surgery short of nephrectomy to be carried out as an elective procedure when the patient has recovered from the acute sepsis.

The following patient is an illustration: a woman, aged 42, entered the hospital in a septic condition with a history of a sudden onset of severe pain in the left lower abdominal quadrant. Examination showed a mass in the pelvis which was considered an ectopic pregnancy. She was promptly operated on, but no pathology was found. A vital urinalysis was omitted. Her chills and fever continued; the urine showed some pus; an x-ray showed a shadow in the left ureter suggesting calculus. The ureteral catheter encountered an obstruction that when overcome drained out 3 to 4 ounces of thick pus.

Catheter drainage for ten days resulted in complete relief of symptoms, so that an elective pyelolithotomy, resulting in complete recovery, could be carried out.

Anomalies of the urinary tract are most important and can now be recognized in infancy and childhood. Some of these, unless diagnosed and relieved, result in early death or in chronic invalidism.

Many infants and young children are treated for digestive disturbances, malnutrition, or as difficult feeding problems, when the real cause is failure of kidney elimination from lesions in the kidney or kidneys or obstructive conditions in the lower part of the urinary tract. Infection is often present, and it would seem unnecessary to stress the importance of a routine urinalysis were it not still too often omitted. In addition, the mother may notice that the child is continuously wet or voids with great difficulty and evident pain and that the stream is thin and dribbling. A careful physical examination may show a mass over the kidney or an overdistended bladder.

This is well illustrated in the following case. A girl, aged 10½, presented the following symp-

recall cases placed upon observation, in years gone by, awaiting the development of further destruction and nephrectomy. With our knowledge of the great restorative powers of these kidneys and with improved technic and antiseptics along with the increased use of nephrostomy drainage, many of these cases can be given good functioning kidneys. The use of the nephrostomy drainage has played an important part in our ability not only to save kidneys formerly subjected to nephrectomy but also has made the convalescence of most operative renal surgery much less stormy.

We have used for several years a T tube, similar to the tube used in gallbladder surgery, to drain the kidney and ureter following removal of stones from the upper ureter. In the presence of dilatation and infection of the ureter and pelvis above, its use has given much satisfaction. Its use does not appear to prolong drainage from the sinus; only an occasional case will require the passage of a catheter to the kidney to secure closure, but this dilatation of the ureter at the site of the incision may prevent later contracture at that point.

McKenna and Kiefer⁵ in their article on conservative renal surgery in the *Journal of Urology* stress its importance and urge that conservation be more frequently used—not as a necessary operation in poor function of the opposite kidney but as an elective operation. They point out, rightly, the necessity of most careful study preliminary to, and at, the operating table so that a conservative operation may not prove eventually to be a radical operation. Nephrectomy is often the more conservative procedure. However, the literature contains an increasing number of cases with excellent results.

In the surgery of hydronephrosis, plastic operative procedures have contributed much in restoring badly damaged kidneys. Innumerable types of operations upon the pelvis and upper ureter have been devised with Trendelenburg, Ferger, von Lichtenberg, Young, Hinman, Foley,⁶ and many others, making valuable contributions. Not only the indication for plastic operation but the type of operation best suited for the case at hand will frequently require a nicety of judgment not called for in other urologic procedures.

Trauma to the kidney, if not resulting in immediate nephrectomy, may later produce a functionless kidney from obstruction or stone formation. Two measures to prevent this latter result may well be considered. Many writers now believe that exploration of

the kidney, with removal of blood clot and repair, is indicated in a large number of cases and that a better functioning kidney will result. If exploration is not deemed necessary or if the patient's condition will not permit, then later urographic studies at intervals are definitely indicated. Early stone formation and obstructive changes will then allow the correction and the saving of the kidney.

Though this is an elementary review of the physiology of the kidney, factors endangering function, and prophylactic and curative measures to lessen that danger, it is hoped that it will in at least some small way aid in the further promotion of one of urology's primary objectives—the conservation of renal tissue.

Discussion

Dr. Roy B. Henline, *New York City*—I have been extremely impressed by Dr. Heslin's interesting paper.

In the past, most urologists have contented themselves with methods of diagnosing advanced urologic disease and perfecting methods for its correction. It is now apparent that their thoughts are turning to the cause and recognition of early stages of urogenital disease and, realizing its inevitable progression with continued destruction of vital structures, they are attempting by early corrective measures to prevent such progressive destruction.

This attitude seems timely and constructive. Although we may be familiar with the inception of disease, yet, far too often, we neglect these early stages unless severe symptoms demand prompt and continued attention. As symptoms disappear or become less acute, we often "wait" to see what develops and, too often, later find gross destructive pathology that might have been prevented.

It seems to me that the time has come to devote our efforts toward the recognition of early pathologic lesions in the urogenital tract and to devise and practice methods of preventing their progression. To wait until gross pathologic changes have occurred when destruction prevents conservative treatment "is not in keeping with the thoughts of the time in preventive medicine." As pointed out by Dr. Heslin, this has been forced upon us by the discovery of the

ADENOCARCINOMA OF THE CERVIX

BURTON T. SIMPSON, M.D., ALPHONSE A. THIBAudeau, M.B., and EUGENE M. BURKE, B.S., Buffalo, New York

ADENOCARCINOMA of the cervix is a relatively infrequent growth. From 4 to 7 per cent of all malignancies arising in the cervix are placed in this group by various investigators. A survey of the patients presenting themselves at the State Institute for treatment of cervical cancer shows one adenocarcinoma for each twenty-six squamous-cell carcinomas.

Of a total of 93 patients with cervical adenocarcinoma, 63 were selected for study, while 30 were eliminated because the histologic sections were not available for study, because the patient had not received treatment, or because sufficient time had not elapsed for a five-year follow-up.

The clinical symptoms of adenocarcinoma of the cervix correspond closely with those found in squamous-cell carcinomas in this location. The first symptom is usually a watery discharge, which, as the invading tumor erodes small vessels, becomes bloody. Pain, as is common in most cases of malignancy, is a later feature. The gross appearance of the tumor is not indicative of the type of lesion, since either a squamous-cell carcinoma or an adenocarcinoma may present the same clinical picture. When, however, the mucous membrane of the cervix is intact and a growth is found arising from the cervical canal, the natural assumption would be that the growth is an adenocarcinoma. If the neoplasm is of the infiltrating type, it may give little evidence of change in the external surface until extensive invasion of the cervical stroma has taken place. In a tumor of the papillary type, on the other hand, the growth is much more apt to be recognized early, since the outward projections present a definite clinical picture. Definite histologic classification is, as a rule, determined only by biopsy. A careful study of biopsy material is essential, for often a highly anaplastic adenocarcinoma may give a histologic picture not unlike a squamous-cell carcinoma.

The age incidence of adenocarcinoma of the cervix coincides with the age incidence of adenocarcinoma of the body of the uterus

rather than with the age incidence of squamous-cell carcinoma of the cervix and occurs, as a rule, later in life. The youngest patient in the series here reported was 29, while the oldest was 73. Ten per cent of the group were under 40 when admitted for treatment. Sixteen were between 40 and 50, and 19 were in the 50- to 60-year age group. This span of twenty years comprised 56 per cent of the total number of patients. The remaining 34 per cent were over 60 years of age, of which 3 were 70 or older. Thirty-six or 57 per cent had passed the menopause before any symptoms had appeared. Many clinicians feel that lacerations and scars due to childbearing are a causative factor in the production of malignant lesions of the cervix. One author goes so far as to claim that 96 per cent of all cancers of the cervix were in women who had borne children. Others, while more conservative, agree that the ratio is much higher in those women in whom pregnancy has occurred. It has also been held that the change in the cervix during pregnancy due to endocrine stimulation may be an exciting factor in the production of malignancy. In the group of patients in this series 57 were married and 6 were single. It was noted, however, that 20, or 31 per cent, of the patients had not given birth to children, while the remaining 43 had a total of 151 children, an average of 3.5 children per patient. While the above figures are not conclusive because of the small groups under consideration, yet the proportion of malignancies in nonpregnant women is higher than is usually reported. The childbearing group showed that 8 women had 1 child each, 8 had 2, 8 had 3, 7 had 4, 4 gave birth to 5 children, 1 had 6, 3 had 7, 3 had 9, and 1 was the mother of 10 children.

On histologic examination the tumors in the series under discussion were placed in four grades of malignancy depending on the degree of differentiation in the tumor cells. Grade 1 showed malignant epithelial cells arranged in gland formation. This formation was maintained throughout and in some cases assumed papillary tendencies. As the degree of malignancy increased, loss of differentiation and gland formation was found, so that Grade 4 was composed of a solid growth of anaplastic cells with only an occasional at-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

toms: frequency and nocturia from infancy; recurring attacks of sharp pain over the right kidney associated with nausea, vomiting, and fever for the past five months. On examination there was pain and tenderness over the right kidney, an infected urine, and chronic retention of urine ranging from 400 to 700 cc. There were all the bladder changes seen in chronic prostatism with beginning hydronephrosis on the right side and a double kidney with separate ureters on the left side, one ureter being megalo in type.

The cause of this retention was a median bar, which can occur in the women as well as men and is important to remember on this account. As soon as the bar was removed the bladder emptied perfectly and the right hydronephrosis was entirely relieved.

The patient immediately improved, the urine became free from infection, and the parents are so satisfied that they will not allow the megaloureter to be removed. The gain in weight has

been 40 pounds, and the girl feels perfectly well.

The second patient showed the effect of calculus obstruction upon the renal parenchyma and the ability of the kidney to recover after the obstruction was removed.

Because all obstructive lesions do not turn out so happily, it goes without saying that the earlier the diagnosis and treatment, the better will be the result.

The medical man who first sees the patient carries a great responsibility, because upon his action will many times determine whether renal tissue can be saved or will have to be sacrificed later on.

Dr. Heslin mentioned the relationship of renal disease to hypertension and, while more study is necessary to clear up the exact status, a sufficient number of patients has already been greatly benefited, in carefully selected cases, by removal of the diseased kidney to warrant a careful survey of the urinary tract in every case.

SUGGESTIONS FOR MENTAL COMPOSURE AND EFFICIENCY

1. *To secure peace of mind*
 - a. Accept your present lot without fretting.
 - b. Assume that right and justice will ultimately prevail.
 - c. Strive for improvement without hindering the progress of others.
 - d. Avoid controversy by having a clear understanding in dealing with others.
 - e. Regard the achievements of yesterday as foundations on which to build today the temples of tomorrow.
2. *To solve difficulties*
 - a. Act promptly in meeting issues.
 - b. Accept full measure of responsibility.
 - c. Acknowledge faults and make reparation as soon as possible.
 - d. If others are at fault, be lenient in making demands upon them.
 - e. Do not dodge issues or run away.
 - f. Do not seek aid from alcohol or drugs. They only aggravate difficulties.
3. *To reach decisions in important matters*
 - a. Learn relevant facts.
 - b. Learn customary practices.
 - c. Anticipate results from experience of others.
 - d. Compare probable costs with probable gains.
 - e. When all data are available, concentrate on problem and decide promptly.

—*Mental Hygiene News*

PSYCHOLOGIC PREPARATION FOR ANESTHESIA

By the psychologic approach to a patient for anesthesia we mean our first visit to the patient before anesthesia, our method of talking with the patient and suggesting the type of anesthesia to be used for his particular case. Some of you may ask why is it necessary to talk with the patient or his relatives regarding the anesthesia. We answer this by saying that in some communities we are forced to give anesthetics in the presence of relatives or their friends. It would be most unfortunate for the anesthetist if he decided to give a patient a spinal anesthetic and when he started the procedure in the operating room either the patient or the observers expressed their objections. We feel that an understanding beforehand will put the patient in a much better frame of mind for the anesthesia and eliminate the possibility of embarrassment later. By answering the questions of the patient and easing fear, our work is made easier.

The anesthetist does play a very important part in the surgical team. He can make himself more important and appreciated if he insists upon visiting the patient before the anesthesia is given. From his history and physical examination he ascertains the patient's needs relative to sedation, and he also is a better judge as to the proper anesthetic and can do much to put the patient in a proper frame of mind for the approaching operation.—*George S. Michling, M.D., address before the Southern Medical Association*

ADENOCARCINOMA OF THE CERVIX

BURTON T. SIMPSON, M.D., ALPHONSE A. THIBAudeau, M.B., and EUGENE M. BURKE, B.S., Buffalo, New York

ADENOCARCINOMA of the cervix is a relatively infrequent growth. From 4 to 7 per cent of all malignancies arising in the cervix are placed in this group by various investigators. A survey of the patients presenting themselves at the State Institute for treatment of cervical cancer shows one adenocarcinoma for each twenty-six squamous-cell carcinomas.

Of a total of 93 patients with cervical adenocarcinoma, 63 were selected for study, while 30 were eliminated because the histologic sections were not available for study, because the patient had not received treatment, or because sufficient time had not elapsed for a five-year follow-up.

The clinical symptoms of adenocarcinoma of the cervix correspond closely with those found in squamous-cell carcinomas in this location. The first symptom is usually a watery discharge, which, as the invading tumor erodes small vessels, becomes bloody. Pain, as is common in most cases of malignancy, is a later feature. The gross appearance of the tumor is not indicative of the type of lesion, since either a squamous-cell carcinoma or an adenocarcinoma may present the same clinical picture. tempt at gland formation. Grades 2 and 3 present intermediate histologic pictures in which the differentiated glandular structure shows gradual changes into solid growth of undifferentiated tumor cells. In our group of patients, 15 were placed in Grade 1, 21 in Grade 2, 18 in Grade 3, and the remaining 9 in Grade 4. Based solely on their histologic grades, Grade 1 showed 60 per cent alive for five years; Grade 2, 38 per cent; Grade 3, 33 per cent; and Grade 4, only 11 per cent. It was consistently found that the more differentiated tumors were radioresistant; their rate of growth was slow with a tendency to remain localized and, consequently, a higher percentage of cures was noted. The more anaplastic growths, while more radiosensitive, showed more rapid growth and wide infiltration and gave rise to early metastases, resulting in a much lower rate of cure.

Dependent upon their localization or extension, the malignancies under study were placed in their respective clinical groups. In the lowest groups are those tumors in which the neoplasm was confined to the cervix. The intermediate groups comprised those tumors in which localized extension was noted, including infiltration of the broad ligament without uterine fixation. Patients in whom extensive infiltration, together with metastases, was found were placed in the high clinical group. The clinical group into which the patient was placed usually decided the ultimate fate of that individual. The histologic grade, however, was a factor to be considered in each individual case, because those patients in a low or intermediate clinical group had a much better prognosis when their tumor cells were found to be in a low histologic grade. In our series of patients alive and well for five years or over, it was noted that 46 per cent were placed both in the lower clinical groups and in histologic Grades 1 or 2, while Grade 3 and Grade 4 tumors in the same low clinical group showed only 25 per cent alive for the same period. In the intermediate clinical groups tumors of Grades 1 or 2 showed 25 per cent of five-year cures, while in the same clinical groups tumors of Grades 3 and 4 were found to have only 4 per cent alive after five years. In the high clinical groups there were no five-year survivals. Of those who succumbed to the disease, 15 per cent were in the low clinical and histologic groups, while the remaining 85 per cent of fatalities were in histologic Grades 3 and 4 or in the high clinical groups.

The duration of symptoms in these patients

showed a great variation. Some gave a history of disturbances for only a few weeks before examination, while others had suffered from irregular menstrual function together with discharge and pain for several years. They were divided into three classes: first, those with demonstrable symptoms under one year. Twenty-seven patients fell in this class. The second class, composed of 24 patients, consisted of those with symptoms for over one and under three years. The third class, comprising 12 patients, were those in whom abnormalities had been observed for over three years. It was found that of those in the first class 40 per cent had tumors in the histologic Grades 1 or 2; 60 per cent, in Grades 3 or 4. In the second class with symptoms for one to three years, 70 per cent had tumors in histologic Grades 1 or 2; 30 per cent, in Grades 3 or 4. Among patients with symptoms three years or over, 75 per cent had tumors in histologic Grades 1 and 2; 25 per cent, in Grades 3 and 4. This confirmed the general clinical observation that tumors of a low degree of malignancy may persist for many years and, while giving rise to symptoms indicative of malignant change, may remain localized and fail to develop metastases. On the other hand, highly anaplastic malignant infiltrating growths give rise to severe disturbances early and cause the patient to seek advice more promptly.

One case in the series is of sufficient rarity to warrant special mention. This was a mucoid adenocarcinoma arising in the cervix. The patient was 67 years of age, was married, and had borne 2 children. Two months before admittance she noted a bloody discharge with some pain. Examination revealed that the tumor process was confined to the cervix. The biopsy showed a growth composed of connective tissue in which large plaques of mucoid material were found. Interspersed throughout the mucoid tissue were areas of small, round, epithelial cells. In some fields the cells were found in glandular formation, while in other areas the cells were found singly or grouped together in small clumps. Following treatment this patient has remained well for fourteen years.

In the group of patients with adenocarcinoma of the cervix only 10 had received treatment before admittance to the Institute 9 of whom had been treated surgically. One had had one course of radiation therapy. Of this group, 3 have survived five years and 7 have died of the disease.

Treatment at the State Institute consisted

of interstitial radiation with gold seeds together with intracervical radiation with tandem tubes of 50 or 100 mg. of radium. Following this, a course of external irradiation with 200 kilovolts was given. Following this course of treatment, of the 63 patients considered, 24, or 38 per cent, are alive and have remained well for five years or more.

Conclusions

1. Adenocarcinoma of the cervix is a relatively rare condition.

2. The duration of the disease is closely

allied with the histologic group in which it will fall.

3. While the clinical grouping is the paramount factor in considering the prognosis, the histologic grade has a definite bearing on the end result.

4. In our series women who had not borne children were found to have adenocarcinoma of the cervix in a higher proportion than is usually reported.

5. Thirty-eight per cent have survived for five years under treatment that consisted mainly of radiation therapy.

PSYCHOLOGIC EFFECTS OF AIR RAIDS

The stimuli presented by a heavy air raid are far more intense and more terrifying than civilized human beings normally experience. Previous to observations in Britain many psychologists were apprehensive lest they lead to widespread panic and hysteria. This has not proved to be the case, says P. E. Vernon of the University of Glasgow writing in the *Journal of Abnormal Psychology* for October, 1941. The author has studied the observations and experiences of trained psychologists and psychiatrists, many of whom have undergone frequent raids in various parts of the country, including London.

Reactions to an air raid seem to be influenced chiefly by what previous experience one has had of raids. At first, the mere sound of the sirens frightened people, but before the end of 1940 Londoners were generally taking no notice of them unless accompanied by the noise of planes, gunfire, or bombs. In other parts of the country every degree of reaction to the warnings between the two extremes may be observed. The presence of a few planes overhead during daytime also soon ceases to affect most people. Acclimatization even to heavy raids at night is remarkable. Before long a considerable proportion manage to sleep in their own homes. More, perhaps, go to shelters or to some room in the house regarded as safe.

There is a moderate correlation between poor adaptation and age. People whose houses have been demolished or who have experienced an unusually severe blitz often regress for a time and show less habituation and more nervousness during the next few raids. A reversion occurs also during a long spell of immunity from raids, when emotional tension and fear seem to decrease. The infrequency of overt manifestations suggests that there is a certain amount of repression by social attitudes or by the ego-ideal.

Chief of the psychologic outlets or palliatives are the presence of a group, and activity. Persons of higher socio-economic class and education seem, in general, to be less attracted and less affected by social influences. Description of

what it feels like when bombs fall close suggests that there is commonly a confused state of emotional shock, a mixture of bewilderment, apathy, and depression (perhaps combined with physiologic effects of blast) persisting for several hours. However, a good deal of habituation occurs. Persons with a job to do mostly recover their poise readily and set about rescue work, fire-fighting, etc., immediately.

With regard to mental disorders attributable to air raids, psychiatrists seem to agree that (1) there have been some cases of mental disorder due to air-raid strain in subjects with an unfavorable history. Terror or sensations from blast here are less important than indirect effects such as extreme fatigue, dislocation of normal living, etc. (2) There have been fewer cases of neurosis than expected. (3) There have been no new or unexpected types of air-raid neurosis. (4) Among persons showing neurotic trends before heavy raids began, about one-half have shown no change; about one-fourth have become worse, and one-fourth actually improved. Psychotics are reported as being impervious to the effects of raids. Epileptics do not show any increase in fits.

The cases of mental disorder produced seem to fall into (1) acute terror and confusion, akin to so-called shell shock; (2) hysteria; (3) more serious cases ranging from acute or chronic anxiety states to psychotic reactions of a manic or hallucinated type. In general, the psychologic disorders would seem to be much less serious than the social disorganization consequent on the destruction of homes, disruption of communication, etc. Minor effects of raids, seen particularly at first, are irritability, depression and lowering of confidence, lethargy, slight dissociation of personality, increased smoking, and excessive talking about the raids. Raids seem to have less effect on children than adults. Since both adults and children show a surprising capacity for coping with fear in a psychologically satisfactory manner, it must be far more susceptible to control by social attitudes and by suggestion than has been supposed.—Abstract from *Library, Neuropsychiatric Institute of the Hartford Retreat*

THE UTILIZATION OF PUS IN THE TREATMENT OF PYOGENIC DISORDERS

ISAAC J. ARNSSON, M.D., Buffalo, New York

THE medicine of ancient times recognized the value of a certain kind of pus which it labeled as *pus bonum et laudabile*, or good and laudable pus.

Without going into a lengthy discourse about the significance of pus as such, it should be sufficient to mention a few known facts about it.

As a mechanical and biochemical defense measure of the body against the invaders, it contains the parasites in every conceivable stage of deterioration, their ectotoxins and endotoxins, as well as the entire complex of the biologic defense apparatus with its cellular and humoral components. Positive results have been obtained in complement fixation with pus or focal secretions. Positive skin tests with pus material, as in the Frei test, demonstrate the presence of specific elements in it. In short, pus represents the first and important line of defense which the body throws up against the invader.

The idea of utilizing it for the offensive is not new in the history of medicine. The practical handicap was the form in which the pus could be used.

In 1920 Dr. Dietrich¹ was testing out the germicidal properties of "yatren," an organic preparation in which an iodine atom is bound to a sulfon-o-oxy-benzol-pyridine radical. It is soluble in water up to 5 per cent. In animal experiments he could demonstrate that mice in which lethal doses of pneumococci culture, mixed with a 2½ per cent yatren solution, were injected continued to live, whereas the control animals injected with the same amount of pneumococci culture without the yatren all died. He also demonstrated that 5 per cent yatren solutions could be given intravenously without any damage to the animal.

In 1925 Dr. Orsos,² of Hungary, continuing the work with yatren, reported on a method of preparation of an auto-pus vaccine, which, due to its simplicity, could be prepared by any practitioner in the routine office work and without an elaborate bacteriologic instrumentarium. He used this vaccine primarily in gonorrhea and furunculosis but recommended it for any staphylococcal or streptococcal infection.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

A year later Dr. von Berde,³ also of Hungary, came out with a bacteriologic criticism of this method. He found that the vaccine still contained living microorganisms even if they proved to be less virulent after culturing and reinoculating them into animals. He speculated upon dire consequences that might arise if, for instance, an anthrax pustule should be mistaken for a boil and an Orsos vaccine prepared from it and given. Admitting, however, that the therapeutic results obtained were by far superior to any other method, he pointed out that the yatren in the ready vaccine was only in a ½ per cent solution and advised the use of the vaccine not earlier than twenty-four hours after its preparation.

For over a year we have followed the method of preparation as given by Orsos and never encountered the slightest complications. Shortly after appearance of von Berde's work, we slightly modified the method of vaccine preparation, securing its safety without diminishing its therapeutic value.

Orsos prepares his vaccine by putting 0.06 Gm. of the yatren powder into a sterile mortar, adding 2 to 3 platinum loops of pus to it grinding it for four to five minutes with a pestle, adding 1 to 2 drops of sterile water, grinding it again until a consistency of porridge is obtained, and adding, under constant stirring, the balance of water (8 cc.). According to Orsos, the vaccine is ready for use in eight to ten minutes, and the injections are given intravenously every other day, beginning with 1 cc. for the first, followed by 2 cc. for the second and the third, and the balance for the last injection. Our method of preparation differs from Orsos's only slightly. After the first two drops of water are added we grind it thoroughly for five minutes; then we add 1 cc. of water, stir it, and let it stand for fifteen minutes. This permits a saturated (i.e., 5 per cent) solution of yatren to work for twenty minutes on the microorganisms and carries the sterilization process further than in the original method. We have never been able to grow any microorganisms from vaccine prepared in this way.

From August, 1926, to August, 1941, we used this vaccine in 150 patients in private practice. The ages of the patients were be-

tween 8 and 61. The conditions in which it was used are seen in the following table:

Furuncles	122
Carbuncles	5
Subaxillar abscesses	4
Pararectal abscesses	2
Abscesses in a drug addict	1
Folliculitis capitis abscedens et suffodiens	2
Folliculitis decalvans	1
Panaritium	1
Acne conglobata	3
Hordeola	3
Dacryocystitis suppurativa	1
Pyoderma in an amputation stump	1
Staphylococcic septicemia	2
Generalized dermatitis	2
Total	150

A detailed analysis of each group is necessary for a proper evaluation of this method.

The largest group is that of furunculoses, the majority of which were of a chronic type with a previous history of various treatments, including the use of stock and conventional autovaccines. In 12 cases the localization was on the face, and in 5 of these lymphadenitis and chills were present. Eleven cases responded at once and made an uneventful recovery. One, with a large furuncle in the introitus nasi of only four days' duration, had squeezed it before consulting his physician. When seen, he presented an edema of the corresponding side of the face and eyelids and complained of severe headache and repeated chills and fever. A vaccine was prepared and given, but the patient died forty-eight hours after the first injection, which did not alter the course of the disease in any way.

Of the remaining 110 cases of furunculosis, 5 cases had a relapse after four injections but did not show relapses after eight injections. Three cases showed relapses even after a series of twelve injections. For the group of furunculoses the vaccine gives 3.28 per cent failures.

Five cases of carbuncles were treated. Two were in diabetic patients. After four injections they healed and no relapses were observed. A third case had a carbuncle on the neck the size of a fist, which was opened by the family physician two weeks previously but did not show any tendency to heal. After the first injection a profuse drainage started, and after three more injections the swelling was completely gone and the lesion was

rapidly healing. It closed completely one week later. Two more cases cleared up with four injections each.

Four cases of subaxillar abscesses responded to vaccine and were not followed by relapses. However, eight injections were required in each of these cases for a complete recovery.

Two cases of pararectal abscesses were treated. Each received four injections. One developed a relapse after eleven months and was treated again.

The vaccine had no effect in a case of abscess formation in a morphine addict.

Two cases of folliculitis and perifolliculitis capitis abscedens et suffodiens of long duration and histories of varied therapy, including x-ray, cleared up after four injections each.

The vaccine had no effect in a case of folliculitis decalvans.

A case of recurrent panaritium cleared up after four injections. No relapse has been observed in a period of two years.

Three cases of acne conglobata were treated. The vaccine was successful in only one of them and only as far as abscess formation was concerned.

Three cases of hordeola were treated—all of a chronic type of over three months' duration. Treatment was successful in 2 cases. The third did not clear up after eight injections and the patient declined to have more.

One case of dacryocystitis was sent by an ophthalmologist for Orsos vaccine treatment. Every conceivable previous therapeutic procedure, including repeated surgical draining, had failed. Six injections of autopus vaccine cleared up the condition.

One case of pyoderma in an amputation stump cleared up after eight injections.

One case of a chronic staphylococcic septicemia was treated repeatedly with the Orsos vaccine. Although the injections were improving his condition temporarily, the patient finally succumbed to the infection.

Similarly unsuccessful was the vaccine in a case of subacute staphylococcic septicemia which followed a carbuncle on the neck in a patient recovering from an appendectomy. The carbuncle was incised and drained; a septic temperature and a heart lesion followed. The vaccine was tried as a last resort and, although the carbuncle had diminished to one-half the size in the following two weeks, the patient did succumb to his heart lesion. It seems definite that septicemias are not the field for Orsos vaccine. Both of these cases were treated in the presulfanilamide era.

Two cases of generalized dermatitis of an erythroderma type were treated. One case cleared up completely; the other was not influenced by the vaccine.

A characteristic feature after the injection of the vaccine is the development of leukocytosis (15-25,000). Clinically, a profuse drainage sets in after the first or second injection. The healing process is a rapid one. As a rule, no untoward effects are observed. The temperature may rise 1 or 2 degrees after the first injection. A slight headache is complained of in about one-fourth of all cases. No alarming symptoms of any kind were ever observed, not even during the time when the preparation of the vaccine was done according to original method.

Contraindications are the same as for any other intravenous injection.

Conclusion

In our experience the auto-pus therapy as recommended by Orsos and modified by us compares favorably with all other conventional methods of treatment of acute and chronic pyogenic dermatoses. The advantage is the simple and rapid preparation of a "vaccine" followed by immediate administration and a rapid response.

The purpose of this report is to save from oblivion an excellent method of treatment which unjustly seems to have been discarded only on the strength of purely theoretic reasons mentioned above.

Discussion

Dr. Harold L. Walker, *Elmira, New York*—Dr. Arnsson and some of the earlier workers such as Dietrich, Orsos, and von Berde were convinced that the Orsos autopyovaccine was definitely of greater therapeutic value than vaccines prepared from bacterial cultures. If this is true, there are three points that need consideration—namely: (1) What would be the

therapeutic effect if yatren alone were injected intravenously? (2) How does yatren affect the endotoxins, exotoxins, and antitoxins contained in the pus? (3) Are there any advantages to the intravenous administration of a vaccine as compared with the subcutaneous or intradermal methods?

(1) With regard to the intravenous injection of yatren, Orsos,¹ in 1938, stated that yatren used alone had no therapeutic value and that it passed through the blood stream and was secreted by the kidneys unchanged.

(2) The question as to the effect of yatren on the pus can be answered as follows: Dr. Arnsson has shown that yatren killed the organisms present, provided the method he outlined was carefully followed. Orsos believed that although yatren killed the organisms, it had less effect on the bacterial proteins than the admixture of urotropin, phenol, or the use of heat, all of which have been employed to sterilize vaccines. In addition, yatren did not destroy the exotoxins, antitoxins, or endotoxins that the pus contained. Orsos demonstrated this by titrating the amount of antitoxin present. He believed that herein lay the chief advantage of his vaccine, stressing the fact that the therapeutic results were so immediate because of the large amount of antitoxin it contained.

(3) The problem as to the relative values of the various methods of administration of a vaccine is still an open question. Dr. Arnsson used the intravenous method. Orsos believed that any of the three methods—intravenous, intradermal, or subcutaneous—were of value, although he preferred the intravenous method because he encountered few untoward effects in large series of cases.

Ayres, Anderson, and Foster,² in 1937, emphasized the fact that they employed the intravenous method of administering vaccines. They mentioned that recent studies had demonstrated that the intravenous method of administration of vaccines, rather than the subcutaneous or intradermal methods, resulted in a higher degree of immunization and that a desensitization to bacterial proteins developed, while occasionally an increased sensitivity to bacterial proteins followed the administration of vaccines by other routes.

The training of interns in the Columbia City Hospital does not include the niceties of diplomacy. At the meeting on anesthesia Dr. Reese gave himself up to an impassioned eulogy of modern methods:

"Take the case of the woman operated on this

very morning, who would be dead now were it not for intratracheal intubation. . ."

From the back of the room came the excited voice of Intern Treska:

"But, Dr. Reese, that woman did die."—*Martin O. Gannett, M.D., in Medical Economics*

DILUTE AND CONCENTRATED PREPARATIONS OF THE TOCOPHEROLS (VITAMIN E) IN THE TREATMENT OF FIBROSITIS

CHARLES LEROY STEINBERG, M.D., Rochester, New York

VITAMIN E is not the name of a single chemical substance. It contains at least three definite chemical substances designated as alpha, beta, and gamma tocopherol, the antisterility potency of each being approximately in the ratio of 9, 2 $\frac{1}{2}$, and 1, respectively. The chemical structures of these three tocopherols have been determined, and alpha tocopherol has been synthesized successfully. Alpha tocopherol is obtained by allophanation of the vitamin E rich concentrate in the form of its allophanate of melting point 160° (Evans, Emerson, and Emerson¹). By careful saponification of the esters, the tocopherol itself is obtained as a pale yellow oil with all the properties of the above concentrate. The yield varies much and amounts at best to 1 Gm. of tocopherol allophanate from 1 Kg. of wheat germ oil. Its formula is C₂₉H₅₀O₂. Fernholz² has advanced the structural formulas as shown in Fig. 1.

Beta tocopherol crystallizes as the allophanate of melting point 146° from the mother liquor of the alpha tocopherol allophanate of allophanated wheat germ oil. The yield is variable, at times greater, and frequently less, than the alpha tocopherol

John³ gave it the formula C₂₈H₄₈O₂. Its structural formula is shown in Fig. 2.

Gamma tocopherol was isolated by Emerson, Evans, and others⁴ from cottonseed oil as the allophanate of melting point 138°. It is isomeric with beta tocopherol of the formula C₂₈H₄₈O₂ and equals this also in biologic activity. By thermal decomposition of gamma tocopherol, pseudocumhydroquinone is obtained.

The commercial vitamin E preparations are evaluated by biologic tests expressed in rat units, fertility dosage, Pacini-Linn units and, recently, by the percentage of alpha and beta tocopherol. A rat unit (RE) is that amount of vitamin E which in a solitary dose will prevent resorption-sterile female rats during the twenty-one days of pregnancy, enable the rat to give birth to at least some living young. The Pacini-Linn unit is calculated by the formula 1,000 × mg. where mg. is the weight of the vitamin E concentrate that must be administered by mouth in daily doses in order to prevent resorption sterility in female rats. The Pacini-Linn units correspond to 0.1 Gm. The percentage of alpha + beta tocopherol × 100, by coincidence, approxi-

Medicament Employed	Cases Treated	Marked Improvement	Slight Improvement
Dilute vitamin E (wheat germ oil)	30	28	2
Concentrated vitamin E (tocopherex)	20	30	

mates the Pacini-Linn units per gram.

Vitamin E is widely distributed in nature. Dried wheat germ requires 250 mg. as a curative dose; wheat germ oil, 75 mg.; fresh green lettuce, 2.5 Gm.; dried green lettuce, 300 to 500 mg.; peanut and cottonseed oil, about 1 Gm.; and fruits such as oranges and bananas, 20 to 30 Gm. The curative dose of palm, linseed, and soy oil is 1 to 2 Gm.; hog fat, 3 to 5 Gm.; beef muscle, 3 to 5 Gm.; and beef liver, 5 to 10 Gm.

Evans and Burr⁵ were the first investigators to describe a spastic paralysis occurring in the suckling young of rats when the mothers are deprived of vitamin E. These sucklings begin to show difficulty in regaining their limbs when placed on their backs when 21 days old. The disease increases in severity during the ensuing four to five days, and by the twenty-fifth day of life practically all the animals destined to develop the disease will exhibit it. About 35 per cent of the affected animals die, 17 per cent recover completely, and 48 per cent continue to exhibit paralysis of some limb or body group of muscles throughout life. There are marked variations in these results. All attempts to cure the disease after it has been established for several days fail. However, the disease is prevented if the mother's diet is shifted from a vitamin-E-deficient diet to one rich in vitamin E on the day of the birth of the rats. It is already too late to forestall disaster if the shift to a vitamin-E-rich diet is delayed until the earliest appearance of paralysis in any member of the litter. Einarson and Ringsted⁶ have shown that diets deficient in vitamin E will cause similar changes in adult rats. Blumberg,⁷ Madsen,⁸ Morgulis and Spencer,⁹ and Morgulis, Wilder, and Eppstein¹⁰ have stressed the importance of deficient vitamin E diets causing primary muscular dystrophy.

Three clinicians have recently reported excellent results in the use of vitamin E or the synthetic tocopherols in the treatment of primary muscular dystrophies or of muscular dystrophies resulting from neurologic conditions. Bicknell¹¹ gave 1/2 ounce of dried wheat germ to 18 patients with muscular dystrophies. Improvement was noted in 12

cases; the remaining 6 cases showed no improvement. The period of treatment varied from six weeks to eighteen months. The shortest period of treatment in the improved group was two months. Wechsler¹² described 2 cases of amyotrophic lateral sclerosis which improved by treatment with a synthetic preparation of alpha tocopherol. Stone¹³ reported excellent clinical improvement in 5 children with muscular dystrophy, in 1 child with muscle atrophy following anterior poliomyelitis, and in 1 child with muscle atrophy after an attack of multiple neuritis. He employed 2 to 6 cc. of wheat germ oil daily. These experiments and clinical reports, particularly those concerning the muscle changes associated with vitamin E deficiency, stimulated me to try the clinical effects of vitamin E in the treatment of fibrositis.

This condition may be defined as an inflammatory reaction of fibrous connective tissue present anywhere in the body. The pathologic picture found in fibrositis and that described by Pappenheimer¹⁴ as occurring in sucklings on a deficient vitamin E diet are practically alike except for the formation of palpable fibrous nodules in the former. Fibrositis may occur as a primary disease or as a secondary disease. Internists are familiar with the muscle pain, swelling, and pain associated with atrophic arthritis or gout. They have seen painful swollen bursae associated with many of the rheumatic diseases. However, few are familiar with the disease as a primary one. Many common diseases are, in fact, evidences of primary fibrositis but masquerade under various titles. These are variously diagnosed as lumbago, torticollis, muscular rheumatism, tendinitis, periarticular fibrositis, panniculitis, myositis, etc. A working classification of diseases of the muscles is given below.

- I. Parenchymatous myositis
 - (a) Suppurative
 - (b) Nonsuppurative
- II. Myopathies
 - A. Primary myopathies
 1. A heterogeneous group such as pseudohypertrophic, fascio-scapulo-humeral, bulbar, juvenile, scapular, infantile hereditary
 2. Myasthenia gravis
 3. Amyotonia congenita
 4. Myotonia congenita
 5. Myotonia atrophica
 - B. Progressive nuclear muscular atrophy

TABLE 2.—SECONDARY FIBROSITIS

Primary Disease	Total No. of Cases	Improved	Unimproved
Atrophic arthritis	4 (concentrated vitamin E) 20 (dilute vitamin E)	1 8	3 12
Hypertrophic arthritis	2 (concentrated vitamin E) 20 (dilute vitamin E)	0 0	2 20
Senile muscle changes	3 (concentrated vitamin E)	1	2
Psychosomatic rheumatism*	2 (concentrated vitamin E) 8 (dilute vitamin E)	0 0	2 8
Sciatica	1 (concentrated vitamin E) 3 (dilute vitamin E)	1 0	0 3
.	4 (concentrated vitamin E)	3	1
.	1 (concentrated vitamin E)	0	1
Gout	1 (concentrated vitamin E) 1 (dilute vitamin E)	0 0	1 1

* These are not cases of secondary fibrositis and, therefore, have been excluded from the totals.

1. Mainly of small muscles of hands
2. Hereditary, familial, of infancy and childhood
3. Subacute and chronic poliomyelitis
4. Progressive bulbar palsy
5. Chronic progressive ophthalmoplegia

III. Interstitial myositis

A. Myositis ossificans

B. Intramuscular fibrositis

1. Primary (muscular rheumatism, lumbago, torticollis, etc.)
2. Secondary (atrophic arthritis, rheumatic fever, gout, etc.)

The first group of cases studied¹⁵ were given wheat germ oil in doses ranging from 2 to 8 cc. This group included 30 cases of primary fibrositis, 20 cases of fibrositis secondary to atrophic arthritis, 20 cases of fibrositis secondary to hypertrophic arthritis, 1 case of fibrositis secondary to gout, 3 cases of sciatica (cause unknown), and 8 cases of so-called psychosomatic rheumatism (psychoneurotics). All these cases had been observed for a period of three months to two years under different methods of therapy so that their clinical status at the time of beginning vitamin E therapy was "stabilized." The wheat germ oil was given in equally divided doses three times daily. The oil was taken in a tablespoon of milk at mealtime. Many patients complained of the unpalatable taste, some said that the oil repeated.

Of 30 cases of primary fibrositis that were treated with wheat germ oil in doses of 2 to 8 cc. daily, 28 cases were completely relieved of all symptoms. Two cases in this group noticed mild relief from symptoms after having received 3 cc. of wheat germ oil daily for four weeks (see Table 1). The 20 cases of atrophic arthritis with secondary fibrositis (see Table 2) were given 2 to 8 cc. of wheat germ oil daily over a period of two to four months. Eight cases noted definite improvement in muscle

soreness and stiffness. Twelve patients experienced no relief. The 20 cases of hypertrophic arthritis with secondary fibrositis that were given 2 to 6 cc. of wheat germ oil daily over a period of two to six months noticed no improvement in the soft tissue structures. One case of gout was given 4 cc. of wheat germ oil daily for a period of four weeks without relief from extreme muscle soreness. The 3 cases of sciatica that were given 4 cc. of wheat germ oil daily for a period of four weeks noticed no improvement. The 8 patients with a diagnosis of "psychosomatic rheumatism" were given wheat germ oil over a period of two to three months without relief.

The second group of cases were treated with tocopherex. This is a trade name for a product containing the natural mixed tocopherols—alpha, beta, and gamma. This mixture is known to have a minimum anti-sterility equivalent of 60 per cent—viz., for every 25 mg. of the mixed tocopherols which it contains, there will be an antisterility potency equal to at least 15 mg. of pure alpha tocopherol. These tocopherols are stripped from large quantities of cottonseed and soybean oils. At least three distillations, generally four, are involved in special "short path" stills under vacuums ranging down to 1,000 mm. All three of the tocopherols possess antisterility qualities. Which one of these tocopherols is most effective in muscular disorders is unknown. One capsule containing 0.2 cc. of the natural mixed tocopherols (tocopherex) was given three times daily after meals to 36 patients having either primary or secondary fibrositis. The dosage was doubled—that is, 2 capsules instead of 1 were given three times daily—for 2 patients having primary fibrositis. These patients were observed for a period of one to five months under this therapy. If no improvement was observed in the first two to three weeks' treatment, none occurred later under continued therapy with tocopherex. No toxic symptoms were ob-

served. Whereas several patients complained of the wheat germ oil repeating or causing mild gastric disturbances, none reported such untoward effects with tocopherex.

The group treated with tocopherex consisted of 20 cases of primary fibrositis, 4 cases of fibrositis secondary to atrophic arthritis, 2 cases secondary to hypertrophic arthritis, 4 cases secondary to Marie-Strümpell arthritis, 2 cases of psychosomatic rheumatism, 1 case of fibrositis associated with sciatica, 1 case of muscle atrophy associated with combined sclerosis, 1 case of muscle pain associated with polycythemia vera, and 3 cases of muscle pain in senile individuals.

Typical Case Reports

Case 1.—Mrs. A. C., a white woman aged 45, was seen on October 7, 1940, complaining of pain and swelling of the left side of the neck for nine days. There had been no previous infection of the upper part of the respiratory tract, local trauma, or local exposure to chilling. An examination revealed a marked swelling and a local tenderness of the left sternocleidomastoid muscle. The sedimentation rate was 0.08; white blood count, 7,150; red blood count, 4,450,000; hemoglobin, 12.8 Gm. The Schilling differential was: Stabzellen, 11 per cent; segmented forms, 61 per cent; lymphocytes, 21 per cent; monocytes, 3 per cent; eosinophils, 4 per cent. No lymphadenopathy was noted. Fluoroscopy revealed no abnormal masses in the mediastinal area; an x-ray of the mastoid area revealed no bone pathology. The patient was given 1 capsule of the concentrated vitamin E preparation three times daily. The swelling of the muscle was almost entirely gone on November 19, 1940, and was completely gone on November 26, 1940. There has been no recurrence.

Case 2.—I. P., a white woman aged 27, was seen on December 6, 1940, complaining of pain and stiffness of the muscles of her back. She first noticed spasms of the muscles on either side of her spine in the spring of 1939. This "attack" lasted four weeks; it recurred in October, 1940, and had been constantly present until seen on December 6, 1940. Four weeks before first being seen by me, the patient noticed two hard pea-sized nodules in her lower back and on the posterior aspect of the left hip. An examination revealed muscle spasm and tenderness of the erector spinae group and two firm non-tender 1-cm.-sized nodules under the surface of the skin on the posterior aspect of the left hip. The sedimentation rate was 0.22; red blood count, 5,040,000; hemoglobin, 14 Gm.; white blood count, 6,850. The Schilling differential was: Stabzellen, 8 per cent; segmented forms, 43 per cent; lymphocytes, 40 per cent; mono-

cytes, 7 per cent; basophils, 2 per cent. The uric acid was 3.0. She was given 2 capsules of the concentrated vitamin E preparation, and she reported complete alleviation of all symptoms one week later. No nodules were found during this visit.

Case 3.—E. S., aged 31, was seen on April 27, 1940, with a history of a swelling on the dorsum of the left hand of two weeks' duration. An examination revealed a typical ganglion. This was treated by striking the dorsum of the hand with a book. The ganglion disappeared. It reappeared on September 14, 1940, and was successfully treated by similar method. The patient was again seen on December 21, 1940, at which time he noticed nodules on the dorsum of the second left finger and on the inner surface of the right arm. These were typical fibrous nodules about 1.5 cm. in diameter and situated subcutaneously. He had also noticed generalized muscle soreness and vague joint pains for a period of two years. These came in periodic attacks. The sedimentation rate was 0.20; red blood count, 5,630,000; hemoglobin, 15 Gm.; white blood count, 8,800. The Schilling differential was: Stabzellen, 7 per cent; segmented forms, 56 per cent; lymphocytes, 30 per cent; monocytes, 5 per cent; eosinophils, 2 per cent. He was given 1 capsule of tocopherex three times daily. He noticed marked relief in the muscle soreness in a period of two weeks; there was no change in the nodules.

Case 4.—E. R. F., a white man aged 48, was seen complaining of muscle pain and soreness of the erector spinae group of muscles on and off for a period of twenty-five years. On April 15, 1940, he complained of severe pain over the posterior aspect of the right shoulder. An examination at this time showed a swelling and a tenderness of the right trapezius muscle. He was treated by rest and local heat. However, he continued to complain of muscle pain and stiffness in different groups of muscles until December 28, 1940, at which time he was given 1 capsule of tocopherex three times daily. One week later all the muscle soreness and pain had disappeared. The sedimentation rate was 0.10; red blood count, 5,710,000; hemoglobin, 16.5 Gm.; white blood count, 8,500. The Schilling differential was: Stabzellen, 5 per cent; segmented forms, 64 per cent; lymphocytes, 28 per cent; monocytes, 2 per cent; eosinophils, 1 per cent.

Summary

There are four groups of vitamin E products available on the market: (1) natural products such as wheat germ, lettuce, alfalfa, etc.; (2) in more concentrated form such as wheat germ oil; (3) in extremely concentrated products such as that obtained by special distillation (tocopherex); (4) a synthetic product

(ephynal acetate). All these substances except the last contain alpha, beta, and gamma tocopherol. The synthetic product contains only d-1 alpha tocopherol. The synthesis of the latter substance is simple. Phytyl bromide XXVI is condensed with pseudocumohydroquinone by the aid of zinc chloride to give an almost 100 per cent yield of d-1 alpha tocopherol. This synthesis was first carried out by Karrer and his associates. The more stable acetic acid ester of d-1 alpha tocopherol is available commercially as ephynal acetate. All the aforementioned substances possess antisterility potency. The exact factor dealing with normal muscle metabolism has not yet been determined. Both wheat germ oil and a concentrated product obtained by special distillation from various oils were used in the treatment of 50 cases of primary fibrositis and 60 cases of secondary fibrositis. Twenty-eight cases of primary fibrositis were completely relieved of all symptoms with wheat germ oil and 20 cases of primary fibrositis were completely relieved of all symptoms with tocopherex. Mild gastric disturbances were noted in several cases receiving wheat germ oil, but none were observed with tocopherex. Tocopherex was more useful in alleviating muscle spasm noted in the back with Marie-Strümpell arthritis. Both products were considered relatively ineffective in the treatment of secondary fibrositis.

Conclusions

1. Wheat germ oil and tocopherex are of value in the treatment of primary fibrositis.
2. The more concentrated preparation of vitamin E, tocopherex, causes less gastric disturbances than wheat germ oil.
3. Further studies should be done to determine which fraction of vitamin E is effective in the treatment of muscle disorders.
4. Continued observation may show that vitamin E may prevent, rather than cure, the severe muscle atrophy found in atrophic arthritis.
5. Primary fibrositis is a metabolic rather than an infectious disease.

Discussion

Dr. Morris Ant, Brooklyn—Dr. Steinberg's presentation of the use of tocopherols in the treatment of fibrositis is timely. The value of this work is especially important since it brings forth the use of a commonly found vitamin into the field of a group of so-called rheumatic diseases. It becomes clear that lumbago, torticollis, muscular rheumatism, tendinitis, and other muscular incapacities may be relieved by means of vitamin E. I should like to draw attention to his report of the excellent results obtained in the cases of Marie-Strümpell disease. An old synonym for this disease is spondylitis ossificans ligamentosa or rheumatoid arthritis of the spine. This coincides with the improvements reported in the primary rheumatic conditions and also with the improvement in the group of rheumatoids because of the secondary involvements of the tendons, muscles, sheaths, fascia, and aponeurosis. These results and my own experience with wheat germ oil for the past six years indicate to me that the tocopherols have a selective affinity for fibrous tissue.

The pathology in fibrositis is assumed to be an ischemic necrosis—necrosis of the ganglion cells, edema, hemorrhage, and the presence of hyaline thrombi in small vessels, all pointing to a circulatory blockage as causing the lesion. Repair sets in with gliosis, a new growth of blood vessels, and reticulum fibers. This recovery is similar to spontaneous recovery in rats with muscle dystrophy due to vitamin E deficiency. However, the rat has no pyramidal tract; therefore, neither the pathology nor the improvement could come by way of the nervous system.

The reports of the cures of amyotrophic muscular dystrophy seem to me not to be due to the good effects of vitamin E on the nerve tissues but to the good effects upon the fibrous muscle sheaths in which the neurites and end plates are located. White fibrous tissue is known to swell in the presence of acids and alkalis. Any toxic agent may create a medium for the swelling of fibrous tissue, or we may postulate that the presence of sufficient vitamin E reserve in fibrous tissue may act as a buffer to keep fibrous tissue in a normal medium.

The observation by Dr. Steinberg that the nuclear muscular dystrophies are not relieved to any extent, or that the hypertrophic osteoarthritic changes are not affected, further hints

served. Whereas several patients complained of the wheat germ oil repeating or causing mild gastric disturbances, none reported such untoward effects with tocopherex.

The group treated with tocopherex consisted of 20 cases of primary fibrositis, 4 cases of fibrositis secondary to atrophic arthritis, 2 cases secondary to hypertrophic arthritis, 4 cases secondary to Marie-Strümpell arthritis, 2 cases of psychosomatic rheumatism, 1 case of fibrositis associated with sciatica, 1 case of muscle atrophy associated with combined sclerosis, 1 case of muscle pain associated with polycythemia vera, and 3 cases of muscle pain in senile individuals.

Typical Case Reports

Case 1.—Mrs. A. C., a white woman aged 45, was seen on October 7, 1940, complaining of pain and swelling of the left side of the neck for nine days. There had been no previous infection of the upper part of the respiratory tract, local trauma, or local exposure to chilling. An examination revealed a marked swelling and a local tenderness of the left sternocleidomastoid muscle. The sedimentation rate was 0.08; white blood count, 7,150; red blood count, 4,450,000; hemoglobin, 12.8 Gm. The Schilling differential was: Stabzellen, 11 per cent; segmented forms, 61 per cent; lymphocytes, 21 per cent; monocytes, 3 per cent; eosinophils, 4 per cent. No lymphadenopathy was noted. Fluoroscopy revealed no abnormal masses in the mediastinal area; an x-ray of the mastoid area revealed no bone pathology. The patient was given 1 capsule of the concentrated vitamin E preparation three times daily. The swelling of the muscle was almost entirely gone on November 19, 1940, and was completely gone on November 26, 1940. There has been no recurrence.

Case 2.—I. P., a white woman aged 27, was seen on December 6, 1940, complaining of pain and stiffness of the muscles of her back. She first noticed spasms of the muscles on either side of her spine in the spring of 1939. This "attack" lasted four weeks; it recurred in October, 1940, and had been constantly present until seen on December 6, 1940. Four weeks before first being seen by me, the patient noticed two hard pea-sized nodules in her lower back and on the posterior aspect of the left hip. An examination revealed muscle spasm and tenderness of the erector spinae group and two firm non-tender 1-cm.-sized nodules under the surface of the skin on the posterior aspect of the left hip. The sedimentation rate was 0.22; red blood count, 5,040,000; hemoglobin, 14 Gm.; white blood count, 6,850. The Schilling differential was: Stabzellen, 8 per cent; segmented forms, 43 per cent; lymphocytes, 40 per cent; mono-

cytes, 7 per cent; basophils, 2 per cent. The uric acid was 3.0. She was given 2 capsules of the concentrated vitamin E preparation, and she reported complete alleviation of all symptoms one week later. No nodules were found during this visit.

Case 3.—E. S., aged 31, was seen on April 27, 1940, with a history of a swelling on the dorsum of the left hand of two weeks' duration. An examination revealed a typical ganglion. This was treated by striking the dorsum of the hand with a book. The ganglion disappeared. It reappeared on September 14, 1940, and was successfully treated by similar method. The patient was again seen on December 21, 1940, at which time he noticed nodules on the dorsum of the second left finger and on the inner surface of the right arm. These were typical fibrous nodules about 1.5 cm. in diameter and situated subcutaneously. He had also noticed generalized muscle soreness and vague joint pains for a period of two years. These came in periodic attacks. The sedimentation rate was 0.20; red blood count, 5,630,000; hemoglobin, 15 Gm.; white blood count, 8,800. The Schilling differential was: Stabzellen, 7 per cent; segmented forms, 56 per cent; lymphocytes, 30 per cent; monocytes, 5 per cent; eosinophils, 2 per cent. He was given 1 capsule of tocopherex three times daily. He noticed marked relief in the muscle soreness in a period of two weeks; there was no change in the nodules.

Case 4.—E. R. F., a white man aged 48, was seen complaining of muscle pain and soreness of the erector spinae group of muscles on and off for a period of twenty-five years. On April 15, 1940, he complained of severe pain over the posterior aspect of the right shoulder. An examination at this time showed a swelling and a tenderness of the right trapezius muscle. He was treated by rest and local heat. However, he continued to complain of muscle pain and stiffness in different groups of muscles until December 28, 1940, at which time he was given 1 capsule of tocopherex three times daily. One week later all the muscle soreness and pain had disappeared. The sedimentation rate was 0.10; red blood count, 5,710,000; hemoglobin, 16.5 Gm.; white blood count, 8,500. The Schilling differential was: Stabzellen, 5 per cent; segmented forms, 64 per cent; lymphocytes, 28 per cent; monocytes, 2 per cent; eosinophils, 1 per cent.

Summary

There are four groups of vitamin E products available on the market: (1) natural products such as wheat germ, lettuce, alfalfa, etc.; (2) in more concentrated form such as wheat germ oil; (3) in extremely concentrated products such as that obtained by special distillation (tocopherex); (4) a synthetic product

INDUSTRIAL OTOLOGY IN CAISSON WORKERS

RALPH ALMOUR, M.D., F.A.C.S., New York City

THE otologic conditions that are peculiar to compressed air work are well known and are established entities. The earliest descriptions of these aural disturbances date back more than a century. In 1820, Hamel¹ reported severe pain in the ears during a descent in a diving bell. His observation was the first attempt to estimate the cause and suggest a means for preventing the illness following submersion, even though work in compressed air is recorded as having been performed at the siege of Tyre in 333 B.C.² Not until Triger employed compressed air in 1839³ to keep back the water entering a mining shaft was the first inkling afforded as to the proper means of overcoming the lesions that result from working in compressed air. He was the first to use a chamber at the top of the tube, which for practical purposes was an "air lock," even though it was merely utilized to permit men and materials to enter and emerge without loss of the pressure maintained within the tube.

Triger's success in overcoming engineering problems hitherto considered insurmountable led to a more widespread use of his methods. In 1854, Pol and Watelle reported their observations of 64 men who were working in approximately 36 pounds per square inch air pressure.⁴ They reported that pain in the ears and diminution in hearing while being "locked-in" were among the many complaints noted. In 1860, François⁵ reported progressive impairment of hearing and pain in the ears and some cases of purulent otitis in compressed air workers. He was the first to propose rules of decompression for men working in this field. It is interesting to note his regulations. At that time he recommended that compression to $\frac{1}{4}$ to $\frac{1}{2}$ atmospheric pressure should consume four to five minutes. Also, atmospheric pressure required twelve minutes in order to get the worker acclimated.

Jaminet,⁶ in 1871, cautioned against "too sudden a transition from normal atmosphere to an over-condensed one." The monumental work of Smith,⁷ in 1873, was the first lucid description of some of the otitic lesions due to compressed air and the adequate treatment

of caisson disease by decompressing in a medical lock.

Smith's description of the physiologic and pathologic changes in the ear under compressed air deserves repetition: "It is a law of acoustics that within the limits of mobility, the denser the medium through which the sound waves are communicated, the larger the wave, and therefore the louder the sound. This supposes, of course, that the ear itself remains under normal conditions. Such, however, is not the case when the observer is in a highly condensed atmosphere. The unusual pressure upon all parts of the auditory apparatus opposes a mechanical obstacle to the freedom of vibration, which is essential to perfect hearing. Hence, although larger sound waves may strike upon the eardrum, feebler impressions are communicated to the auditory nerve and the sound appears to be fainter than in the open air. Thus, by repeated experiments, I found that a watch that could be heard distinctly at a distance of 18 inches in a very noisy place, could not be heard at a greater distance than 2 inches in the comparative silence of the caisson."

This observation of Smith, while basically correct, does not hold true for the complex work that is now being performed under compressed air. The worker in this field is subjected to industrial hazards that are the same as those encountered by men engaged in occupations conducted under normal atmospheric pressure. There are many otologists who have concerned themselves with this problem. Alt, Heller, Mayer, von Schrötter, and Gomez,⁸ Lester,⁹ Hill,¹⁰ Boot,¹¹ Vail,¹² Lestienne,¹³ Magnotti,¹⁴ Willhelmy,¹⁵ among others, have all been interested in this problem.

The condition most familiar to the physician is that which is commonly called "the bends." From the otologic standpoint this may assume one of two forms. The subject may present a Ménière's symptom complex or there may be an apoplectiform type of deafness. Damage to the perceptive mechanism is rare during compression, although vertigo may occasionally be experienced. There are two theories concerning the manner in which the labyrinth can be involved. One is the hydraulic theory, which proposes that on decompression vasoconstriction occurs in the dermal capillaries, thus causing an engorge-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

From the Department of Otolaryngology, Beth Israel Hospital.

at the specificity of vitamin E for fibrous tissue. The maintenance of normal fibrous tissue metabolism, therefore, depends upon proper nutrition—proper diet with enough vitamin E in the daily intake. We may say, therefore, that wheat germ oil is the lubricating grease for the normal physiology of fibrous connective tissues, just as vitamin A is the lubricating oil for squamous epithelial tissues.

The use of vitamin E becomes a rational treat-

ment in many traumatic skeletal dystrophies affecting fibrous tissues, as well as in a large group of rheumatoid complications. We may now look forward to an increased interest in the treatment of both primary and secondary myopathies by means of metabolic and nutritional agents rather than by sedatives and opiates.

I wish to express my thanks to Dr. Steinberg for his fine presentation on the use of tocopherols.

PHYSICIANS IN CITIES ARE INCREASING FIVE TIMES AS FAST AS POPULATION

Cities of 50,000 and over show a population gain of 2.8 per cent in the last five years (1936-1941). During the same period and in the same cities, practicing physicians have increased 14.4 per cent. In other words, the rate of growth in number of medical men has been five times the rate of growth in population.

These facts are from a study of professional and lay population shifts, based on reports from the U. S. Bureau of the Census and on an analysis of *Medical Economics'* mailing list of more than 130,000 practicing physicians.

The study reveals that only 34 per cent of Americans live in the larger cities mentioned, but that 55 per cent of all active physicians practice there. What's more, the flow of medical men into urban centers is accelerating steadily.

The larger the city, especially above 100,000 population, the smaller the number of people per physician. Obvious results in our metropolitan

areas are (1) too many doctors; (2) not enough patients. All of which helps explain one of the chief findings of *Medical Economics'* Survey of Medical Practice—namely, that the average income per physician becomes progressively smaller as the population of the city increases above 100,000.

The degree of health and wealth enjoyed by a city's population undoubtedly has a marked effect on the doctor's income. Nevertheless, it is still often true that a decline in the number of potential patients per doctor causes a decline in average revenue per doctor.

The practitioner today who wants more patients will generally find them not in the metropolitan areas but in the smaller communities of less than 50,000 people. Fewer physicians are settling in such places, yet population there is growing almost half again as fast as it is in the big cities.—*Medical Economics*

"On blue days when the hunt for truth about people seems futile or when I fear the consequences my more and more open expression of dangerous truth may have for me, I'm bucked up by the memory of Charles Armstrong's chuckle. After he had just dodged dying from the parrot fever he was fighting, he came back to trap the deadly virus of the St. Louis sleeping sickness. Then a mysterious brain malady, caught while studying his sleeping sickness monkeys, knocked him over. But Armstrong got up off the floor."—*Paul de Kruif, M.D., in a testimonial article on Dr. Armstrong, published in The Ladies Home Journal.* [Dr. Armstrong has since received the Sedgewick Memorial Medal, the American Public Health Association's significant award.]

During the Battle for Britain, the British Broadcasting Corporation recorded the sounds of warfare as a medical service. This will be used as a cure for patients driven to neurotic breakdowns by the unaccustomed clamor of air raids. The patient, after the treatment and its aims are explained, is subjected to the sounds that brought about his breakdown. Reassuring and encouraging talks, interspersed with war recordings, build up control and confidence. This conditioning, over a period of time, rids the patient of his fearful anxiety and normalizes reaction. In Washington the War Department recently previewed battle-punctuated sound tracts of a blitzkrieg attack, the first of several hundred that are to be produced to condition United States soldiers against the fear psychosis.

—*Wichita Medical Bulletin*

ness is not diffuse but spotty and streaked. Upon magnification, the injected vessels are seen anteriorly, superiorly, and posteriorly radiating toward the annulus from the hammer handle. The lower, anteroinferior portion of the drum is almost normal in appearance. An important differentiating point between all degrees of blocked ear and the acute catarrhs is the rapid disappearance of otalgia. In acute catarrhal otitis media, intermittent pain persists for several days.

In the blocked ear of second degree three forms can occur. In the *mild* variety one or more hemorrhages within the substance of the drum appear soon after the trauma. They are seen as purplish spots. The most frequent location for a solitary hemorrhage is in the posterosuperior quadrant. The hemorrhage is always sharply outlined and nondissecting, and it does not increase beyond its original size. Multiple hemorrhages do not coalesce. A bulla is never formed and so it cannot be confused with the hemorrhagic blebs of influenza otitis.

In the *moderate* form an intratympanic hemorrhage occurs. Hemorrhage in the drum itself may or may not occur. Contrary to what one would expect, the tympanic membrane is retracted and the osseous landmarks are accentuated. Its color is a diffuse purple. Magnification easily identifies the glistening gray of the epidermal layer through which shines the purple of the intratympanic hemorrhage. Symptomatically, sufferers from these two forms of second-degree blocked ear show no difference as to quantity or duration of their complaints.

In the *severe* form the retraction is extreme and the incudostapedial articulation is visualized. Pressure of this joint against the drum can result in a perforation. Lange¹⁷ believes that this factor accounts for the frequency of hemorrhages in the posterosuperior quadrant. It is often difficult to determine whether the tympanic membrane has been torn through completely, since the edges of small tears heal quickly or are covered with a blood clot. Of the individual layers of the drum, Brügge-mann¹⁸ noted that the epidermal one was lacerated more frequently than the others.

Perforations, when seen early, present ragged margins and are central in type. They may be of any size and may be single or multiple. There may or may not be free bleeding, and the intact portion of the drum may or may not show isolated hemorrhagic spots. This is of the utmost importance for the industrial otologist, because upon several oc-

casions I have heard expert testimony to the effect that hemorrhage from the ear constitutes prima-facie evidence of injury to the internal ear.

It has been my experience that where a blocked ear results in a perforation the drum has been the seat of atrophic changes or old scars; this in itself is evidence of a prior insult to hearing.

The Loss of Hearing Following Blocked Ear

Ninety-three cases of blocked ear have come to my attention from the point of view of compensation. Fifty-five can be considered in evaluating damage from trauma, 15 stated that they had a loss of hearing before sustaining the injury, 9 were seen when at least a week had elapsed following the incident, 8 refused to have their hearing tested and 6 were unquestionable malingerers. The 55 cases under consideration all showed an acute loss of hearing. This loss exhibited no characteristic that could in any way be interpreted as typical, either upon audiometric test or with the tuning forks. In 24 cases a record of the immediate loss showed a drop in the 2,048, 4,096, and 8,192 octaves. In 25 cases the drop was predominant in the 128, 256, and 512 ranges. The other 3, wherein both ears were blocked, showed discrepancies. One showed a parallel loss of air conduction for the upper three tones, while in one a lower tone deafness was noted in one ear and in the other the high tones were markedly depressed.

It has been my experience that in the vast majority of cases of blocked ear without perforation of the drum, hearing returns to within normal limits after the eustachian tube has been rendered patent and after heat, either by short wave or diathermy, has been used to hasten the absorption of hemorrhage. The degree of blocked ear does not influence the time required for the return of hearing to approximate the normal, since the greatest duration of therapy to bring about this therapeutic result occurred in a mild case of first-degree blocked ear. I have found that the average time for bringing the hearing back to normal has been sixteen days: the shortest case requiring four days and the longest requiring twenty-eight.

From an industrial point of view, hearing loss following a perforation of the drum is also difficult to classify. In 2 cases that I have seen, the initial loss was surprisingly little, affecting only the range from 1,024 to 8,192 D.V. The maximum for any one note did

ment of the internal viscera with a resultant predisposition to hemorrhage. The other, the one generally accepted, is that of gas emboli from the liberation of excess nitrogen in the blood.

The auditory phenomena that result from the episodes of faulty decompression can be divided into three groups.

1. Those in which transient auditory and labyrinthine symptoms that subside rapidly and leave no sequelae appear.

2. In certain instances the auditory and labyrinthine symptoms recede slowly and incompletely. There remain, then, a continued or intermittent vertigo, tinnitus, headache, and deafness characteristic of acoustic nerve involvement. Occasionally, a mild spontaneous nystagmus is seen. The Rinne test is positive. Caloric stimulation of the canals reveals a hypofunction. In these cases a gradual amelioration of all symptoms is the rule.

3. The most severe attack on decompression results in a sudden virulent labyrinthitis due to hemorrhage into the internal ear, producing a permanent impairment of either cochlear or vestibular function or both. Magnotti,¹⁴ in experimental work, found alterations in the spiral ganglion due to pressure changes; the cells were markedly distended.

Otitic lesions that occur as a result of a general disturbance happen only during decompression. Passow¹⁵ also corroborates the experimental studies of Alt and his coworkers of hemorrhage in the modiolus, in scala tympani and vestibuli, and in the semicircular canals.

The average otologist is rarely confronted with the acute condition resulting from decompression. "Sand hogs" all carry upon their persons a tag instructing that they be immediately taken to the medical lock if they reach a stage of unconsciousness. He sees, however, the end results of such trauma. He should be acquainted with the reactions due to faulty decompression, since auditory lesions are rarely predominant. It is only in the late stages, sometimes many months after the initial injury, that the otologist sees this type of patient. Therefore, from the industrial standpoint, the deafness due to caisson disease is a negligible incident. Of prime importance to the injured, to his employer, and to the State Board of Workmen's Compensation is the evaluation of the immediate and permanent disability to hearing. Of the several important phases of compressed air work which concern the practicing otologist, the

"blocked ear" is of the utmost importance. The blocked ear is an expression coined by the sand hog to designate any affliction to the drum, middle ear, or both. He attributes this to an inability to equalize the intra- and extratympanic pressure. The blocked ear is usually attendant upon compression in the air lock. The reason for this lies in the anatomy of the eustachian tube; its pharyngeal orifice is resilient, while its tympanic orifice is rigid. Increased air pressure, therefore, easily compresses the pharyngeal opening of the tube.

The main cause of the blocked ear is a certain definite degree of tubal occlusion. Disregarding any carelessness by the lock tender or defects in the pressure controls, a tubal occlusion is the primary factor in the production of a blocked ear in compressed air workers. It should be noted here that all seasoned sand hogs suffer from a chronic hypertrophy of the upper part of the respiratory mucosa. Nevertheless, the principle predisposing cause of a blocked ear is the "common cold." In our state there are specific instructions in our laws that workers in compressed air should abstain from going into "air" when they have a cold. Furthermore, those who have recovered from a coryza should not work in compressed air without medical advice from the physician assigned to the job.

Under normal conditions the sand hog, on being locked in, knows how to equalize the air pressure in his middle ear. He does this by "blowing"—self-inflation and repeated swallowing. The ability to autoinflate is lost when tubal obstruction is present. When this occurs, the lock tender must be immediately told so that he can ease up on the pressure valve. Unless this is done, a blocked ear will occur in the worker.

The man experiences immediate severe pain of a stabbing character in the affected ear and a sensation of fullness. Speech, though sounding hollow and muffled, is heard without difficulty. The term "blocked ear," while in common use among compressed air workers, should be adopted to describe this traumatic condition because it distinguishes it from certain inflammatory lesions that may present a like clinical and otoscopic picture. Furthermore, the term designates the cause, the various pathologic pictures, and the sequelae to be sought for in estimating compensability.

There are two degrees of blocked ear. In the first degree there are noted a marked retraction of the membrana tympani and intense hyperemia. It is distinguished from an acute catarrhal otitis media in that the red-

they resent the interruption in their work. Their sole interest is to get what they call the "passage" to their ear cleared up as soon as possible so that they can get back on the job. Many of them carry nose drops containing some mucosal astringent that will assure tubal patency before going into "air." Once the otologist has re-established tubal aeration, the veteran sand hog rarely reports for further treatment, even though changes may still be present in the drum and middle ear.

This is one of the reasons why it is difficult to evaluate the effect of compressed air work on the hearing of those steadily employed in this work. So-called "company doctors" cannot conduct such a survey, since an attempt at accurate hearing estimation prior to employment has at times been interpreted by union officials as a means to discriminate in the hiring of labor. The imperative need for such testing was obvious to Vail, who in 1929 suggested that "a wide and careful survey must be made to decide whether the percentage of deafness is uniformly high in persons working under compressed air."

After a thorough investigation of this question for over ten years, I submitted my findings and conclusions to the Section of Otolaryngology of The New York Academy of Medicine in May, 1940, which have appeared in *Laryngoscope*, 52: No. 1, 75 (Jan.) 1942.

As I have indicated, there is no definite characteristic of a hearing loss due to a blocked ear. Nor, because of existing conditions in the industry, is it possible to obtain an estimation of hearing acuity, beyond the crudest types of tests, prior to employment, so that all concerned in the evaluation of disability might have a permanent record against which there could be compared a possible future insult to hearing following an episode of blocked ear. And, finally, we must bear in mind that there are various makes of audiometers in use and that even two machines from the same manufacturer may give different curves in the same patient tested by the same person under the same conditions on the same day. Where, as frequently occurs in a contested case, the expert opinion of two otologists is presented to the court, the court for its own information directs an examination by one whom it alludes to as an "impartial" examiner.

Invariably, the hearing tests by all three, often taken on three different machines and under different conditions for sound-proofing, are far apart from one another. The court obviously has not the time to concern itself

with these minutiae, but from the standpoint of the injured, the employer, and the carrier they mean dollars and cents.

In blocked ear there rarely arises the question of complete hearing loss in altercations for compensation. Here, we otologists are called upon to determine the degree of partial hearing loss following this injury and, since the decision of the New York State Court of Appeals in the case of *Bednar vs. Ingersoll-Rand Co.*—where in effect it was decided that *even though no loss of earning power results from the hearing loss sustained*—partial compensation, according to the percentage of loss found, is rightfully due to the injured. The decibel loss is not considered in this decision; nor are the differences that we otologists know exist in the various kinds of audiometers taken into consideration by the referee.

At the present and up until now, I have taken the stand that the worker who, upon several tests at varying intervals up to at least six months, shows a closely identical audiometric loss on the same machine or a similar persistent curve of hearing loss on a like machine from the same manufacturer is the only one whose compensation can be computed on a percentage basis, even though in principle this is wrong. Therefore, I submit:

1. That the clinical picture of the blocked ear is an entity.

2. That the increase in air travel will add to this problem.

3. That the effect of compressed air work upon hearing needs intensive study and that labor organizations should be made aware of this problem.

4. That the estimation of compensability on the basis of percentage of hearing loss due to a blocked ear is as yet not possible and that the Courts, unwittingly, are making us use our pending experimental investigations to serve their practical need for the dole of awards.

5. That in the interim a disinterested board of examiners for hearing estimation be established to which all cases of blocked ear will be referred, wherewith all elements of a controversial nature will be reduced to a minimum.

6. That the otologic profession establish quickly a standard of compensability for a loss in hearing due to the trauma of a blocked ear. I suggest further that this should be extended so as to embrace eventually all losses of hearing function due to injury.

7. That we otologists under the present setup think twice before we contradict one another on a given case. Let us remember

not exceed 30 decibels. This observation is in accord with Vail's,¹² whose case report of a blocked ear with two perforations and active hemorrhage from the tympanic cavity showed similar findings.

Case Reports

First Degree.—E. B., aged 45, seen on September 22, 1938, stated that for the past three days he had had a cold in his head with the classic symptoms of acute coryza. On September 21 he entered the lock and immediately noticed a "blocking" of his right ear. On presenting himself for examination, he had only a slight pain in that ear and a stuffy sensation.

Otoscopic examination revealed a moderate retraction of the right drum and injection of the tympanic vessels. There was no perforation or hemorrhage. The left ear was normal. The mucous membrane of the nose and throat was acutely inflamed, and there was a copious, thin, watery discharge present in both nostrils.

Adrenalization and gentle inflation of the right eustachian tube resulted in an immediate improvement in the patient's condition. I further recommended that he should not be permitted to go into "air" until the condition was completely cleared. It was my opinion that the acute coryza was a contributing factor to the blocked ear. On September 28, 1938, the drum had returned to normal, and no further treatment was required.

Comment: This man was an old experienced sand hog. He would not permit any hearing test. He wanted his ears "cleared" so that he could go back to work. I questioned him, off the record, whether he would like to have his hearing tested and he said to me: "Doc, when you are in this kind of work you got to expect these things. I don't aim to claim compensation; fix me up so that I can get back to work." After much persuasion I was able to have him submit to an audiometer test, which showed, at the time of this particular insult, a 20-decibel loss in his right ear for the 512, 1,024 and 2,048 notes, while his left ear was normal.

Second Degree, Mild Form.—F. R., aged 31, was seen first on November 15, 1934. He stated that he had had a cold in his head for one week. On November 7 he went into compressed air for one hour. Upon emerging from the lock he noticed a bubbling sound in his right ear. He had no complaint until the morning of November 15, when he felt that his ear was clogged and that hearing was diminished.

Otoscopic examination showed a marked retraction of the right drum with an injection of the entire membrane. There was a slight hematoma in the anteroinferior quadrant of the drum. The eustachian tube was completely occluded, but, after shrinking and repeated inflation, patency was re-established. Following this

procedure, immediate improvement was obtained.

Audiometric estimation of hearing revealed only a 10-decibel loss for the 256 and 512 octaves in the affected ear. My opinion was that I did not believe that the compressed air entirely resulted in his condition, since of itself it could not produce a tubal occlusion. I stated that the contributing cause to the blocked ear was the end result of the coryza from which he still suffered.

Moderate Form.—T. L., aged 40, came under observation on November 24, 1937. On the nineteenth of that month, upon coming out of an air lock, he got the "bends." Since that time he had noticed a stuffiness in both ears, a slight diminution in hearing, and some tinnitus.

Examination revealed both drums to be retracted and reddened. There were punctate hemorrhages in both eardrums, and in the right ear there was an intratympanic hemorrhage. On that date the loss of hearing in the right ear, in terms of percentage loss required by the State Labor Department, was 33 $\frac{1}{3}$ per cent, while in the left ear the loss was within normal limits. On December 13, following diathermy and inflation, the hearing in the right ear returned to normal, the intratympanic hemorrhage had completely disappeared, and all evidences of inflammatory reaction had abated.

Severe Form.—P. G., aged 46, was first seen September 23, 1937. Following a cold of six days' duration, he entered the air lock and stated that he soon developed severe soreness in the right ear. He stated that he had been working in compressed air on and off for twenty-four years.

Otoscopically there was a marked retraction of the right drum. In the region of the postero-superior quadrant, an irregular, jagged perforation was evident. This was superimposed upon a markedly scarified tympanic membrane. In addition, there was a large hemorrhagic exudate definitely circumscribed in the antero-inferior quadrant.

It is noteworthy that while no complaint referable to the left ear was advanced, audiometric estimation of hearing showed a 44 per cent loss of hearing in the left ear as compared with a 41 $\frac{1}{4}$ per cent loss in the right ear, which suffered the trauma.

Evaluation of Disability

In this type of industrial trauma the aurist finds himself in a peculiar position when called upon for expert testimony. I have found that it is not the injury itself but the length of time that an individual has been employed in compressed air work. This type of employment pays far above the average, and the old hands take a blocked ear as a matter of course. When they are compelled to go to an otologist

on the job. Dr. Graham Rogers, at that time listed as a medical factory inspector, switched to tunnel work. His early experience in deep-sea diving served him well. He is still, after 34 years, in the Department handling occupational disease cases.

After extensive study not only by our own men but in collaboration with all those engaged in this type of work, including engineers and surgeons, there was promulgated in May, 1922, the Industrial Code Rules relating to work in compressed air (tunnels and caissons) and general tunnel construction. This is the Magna Charta of the so-called sand hogs and muckers. The rules are comprehensive and cover every aspect of this work to safeguard the workers.

Since the promulgation of these rules, the well-known vehicular tunnels—the Holland, Lincoln, several subway tunnels and, last, the Queens Midtown Tunnel—have been constructed without a single death due to caisson disease. During the boring of this last project, the U. S. Bureau of Mines and the U. S. Public Health made studies. One of the results is that in the contract specifications for the new Battery-Brooklyn Tunnel, longest yet to be constructed, there is the compulsory installation of apparatus for alleviation of ear block. This is known as an oxyhelium containing a mixture of 80 per cent helium and 20 per cent oxygen.

These specifications are an outcome of the work of Lovelace, Mayo, and Booth announced in 1939: *The Inhalation of Helium for Alleviation or Prevention of Aero-Otitis Media or Blocked Ear*. It is more specifically due to the experiments by Crosson, Jones, and Sayres, surgeons in the U. S. Public Health Service. They found that 82 of 84 cases of so-called workers "locked-out" were able to continue into compressed air after a few minutes treatment. They also mention "sinus block." This report was published in *Public Health Reports*, August, 1940, and is entitled "Helium Oxygen Inhalations for Ear Block in Compressed Air Workers." If the regulations of our Industrial Hygiene Division in regard to infections of the upper part of the respiratory tract are put into the Industrial Code, which means strict enforcement, the blocked ear or aero-otitis media will surely be on the way out.

Now we come to the recommendations made by Dr. Almour. These are not peculiar to caisson workers. The same, for example, can be made for workers in noisy trades, such as boilermakers. By the way, a special bulletin on *Effect of Noise on Hearing of Industrial Workers*

was prepared under the present Industrial Commissioner, Frieda Miller, and published in September, 1930.

In 1940 it was my privilege to discuss a report of a legislative commission on hearing with the Industrial Board. This report was prepared by members of your section: Dr. Pratt, Dr. Fowler, and Dr. Hambrook. Mention of the name of your secretary, Dr. C. Stewart Nash, was made in the report.

Five recommendations were made. Four of these were favorably commented on by the Industrial Board and forwarded to the Industrial Commissioner. A table by Dr. Fowler for computing percentage disability in reference to the ear was not adopted at this time. I regret now to state that nothing definite has come of these recommendations. Two of them in my mind are essential—namely, the appointment of a qualified otologist and the use of Standard Audiometers in a sound-proof room.

Up to 1936 no compensation was allowed unless there was total loss of hearing in one or both ears. Sixty weeks was awarded for total deafness in one ear and 150 weeks for total deafness in both ears. At present there is allowance for partial loss of hearing based on percentage loss found with an audiometer. Due to this improvement, the number of ear cases, of course, increased. They are sufficient in number to warrant the full-time service of an otologist. We have two eye specialists, and the work in this department meets with satisfaction on all sides. There is no adequate reason why the same cannot be said for an ear department. This is a new field for workmen's compensation, comparatively a virgin field in need of extensive ploughing. We feel there are grounds for just criticism in many phases of our work. There must be cooperation.

In closing may I suggest and urge that this section in some way register a favorable comment on the appointment of a qualified otologist and the setting up of a soundproof room and installation of properly calibrated audiometers approved by the Committee on Physical Therapy of the American Medical Association. This could be done simply by a letter from your secretary to the Industrial Commissioner or to the Director of Workmen's Compensation, Mr. Ralph Boyer, who is eager to aid this work, is alert to the necessity of it, but is apparently hampered by some budget deficiency. Let me say, here, that this paper is responsible for at least one forward step—namely, a special index in our files for nose, throat, and ear cases.

According to a survey made of thirty large American cities, including about one-quarter of our population, marriage licenses issued up to

and including November, 1941, have exceeded those of the corresponding period of 1940 by 8.8 per cent.—*Bull. Metropolitan Life Insurance Co.*

when we are called on for expert testimony that many factors other than our own opinion and observations enter into the final disposition of a case. Courts are not concerned with the medical aspects of a case beyond their desire to determine cause and effect, prognosis as to permanency of the injury, and the estimation of damage from the monetary angle. Here, I submit that a blocked ear per se in the rarest of instances causes a permanent, debilitating and, in my opinion, compensable loss in hearing.

8. That I reiterate Vail's demand for a survey of hearing in compressed air workers. I go further in advocating legislative measures that will compel these artisans to have an accurate estimation of their hearing made before employment so that what we otologists are vitally combating—namely, the increase in the number of the deafened—will be materially furthered.

Discussion

Dr. James W. Babcock, *New York City*—Dr. Almour's comprehensive and interesting paper on a subject in which he has had more experience than most of us has been a pleasure to hear.

My understanding is that the ear conditions produced by going under pressure, although unpleasant enough, rarely produce permanent impairment, although as he pointed out we have no accurate knowledge of the percentage of impaired hearing among experienced workers under

pressure as a whole. But he mentioned at least 1 worker who had a loss of 40 decibels, although he did not complain of a hearing impairment. Probably they all attain some loss after long experience.

The most serious results come from rapid decompression. Those in my experience are due to inner-ear lesions and hearing; while it may improve, it is rarely restored to normal.

The increasing use of flying is yielding many so-called "blocked" ears from rapid descent. Strangely enough, the victims are usually passengers. It seems rare in pilots for some inexplicable reason.

The use of helium as described by W. H. Requarth in the *J.A.M.A.*, April 19, 1941, is interesting, but I have had no personal experience with it.

Dr. William J. Jackson, *New York City*—I have read Dr. Almour's paper with keen interest. Its presentation to you was clear, concise, and thorough. The blocked ear is an entity. Its distinction from the ear condition induced by a true case of the "bends" or caisson disease is a real one. In fact there was not a single caisson disease ear case during the recent construction of the Queens Midtown Tunnel according to the surgeon-in-charge, Dr. Grover Emery. The former happens on entrance to the air lock and the latter on too hasty emergence from the air lock. The former affects the conductive mechanism, while the latter affects the perceptive mechanism of the ear.

It was my pleasure to hear Dr. Almour read his paper on this topic in New York, in May, 1940. It was given somewhat more in detail. Dr. Almour is no tyro in this field. He was the author of a pamphlet of 29 pages entitled, *The Interpretation of Otological Findings in Cases of Industrial Trauma*. This was published in 1924 by the New York State Labor Department. His description of the "blocked ear" is graphic, if not classic. Some cases do result in impairment of hearing. This same condition was described in detail by Armstrong and Heim in the *J.A.M.A.*, August 7, 1937. Their study was confined to aircraft pilots, and they termed the condition "aero-otitis media."

I have been invited here as an otologist representing the New York State Workmen's Compensation Division. As we see chiefly the end results, I do not feel competent to discuss these cases in their acute form and only in small measure from a clinical point of view.

Around 1903 to 1906 the so-called McAdoo Tunnel, the tunnels of the Pennsylvania Railroad under the Hudson and East rivers, and the early subway tunnels were bored. The occurrence of deaths due to caisson disease and explosions induced a special legislative act for appointment of a tunnel inspector in the State Labor Department in 1907. The appointee, a truly able inspector, Mr. Gus Werner, is still

waters that cannot be treated with equal benefit by the various spas in England.

Another instance indicating the importance placed on spas by the authorities comes from the German news flashes as radioed to this country. Under the date of February 15, 1941, a note regarding a special five-year plan for the rejuvenation and reorganization of the Carlsbad Spa was reported. This states that the plan includes sanitary improvements, modernization of the buildings, and the development of a research institute to study the waters. It also suggests that new hotels and other accommodations for visitors will be constructed. In addition, special institutions for study of mineral waters and moors are planned for Franzensbad and Marienbad.

All of these reports from the warring countries abroad stress emphatically the place and importance of the mineral waters and the great value of their proper utilization.

Now we may turn to our own state and give some attention to the facilities that are available in our own spas for the care and treatment of patients. There are six institutions in our state where mineral waters are utilized in the treatment of medical conditions. It is not my purpose today to list each place individually or to discuss in detail the therapeutic indications for the same. It is my desire, however, to point out that these places do exist and to give you some indication of the possibilities for the care of people in them.

There are in these six institutions approximately as many different types of mineral waters. While Sharon Springs, Richfield Springs, and Clifton Springs all utilize a sulfur water in their treatment, it differs to some extent in each of the three places. Alden and Glen Springs have strong saline brines which must be diluted before they can be used for bathing purposes. Saratoga Springs has the naturally carbonated saline-alkaline waters. You can see that with this variety of natural facilities it is possible to select places where the program of treatment can be adapted to the patient's medical condition.

The presence of a healing water alone does not make a spa. Only when facilities are provided for its proper application and where physicians have made a study of the water to see that it is utilized in a regulated program can we say that a spa exists. You will find in the spas of New York State a variation both from the standpoint of physical equipment and medical control. At Glen Springs all patients are strictly under the care of a physician who outlines the program. At

TABLE 1.—SUMMARY OF THE ACCOMMODATIONS AT SPAS IN NEW YORK STATE WHICH ARE AVAILABLE FOR CARE OF PATIENTS

Place	Hotel	Pension with Meals	Rooming House Without Meals	Total
Alden	105			105
Clifton Springs	275	50		325
Glen Springs	150	25		175
Richfield Springs	1,085	35		1,120
Saratoga Springs	2,865	241	215	3,321
Sharon Springs	1,120	181	431	1,732
Total	5,600	532	646	6,778
Number of Guests				
Alden	160			160
Clifton Springs	380 (68 hospital beds)	75		455
Glen Springs	225	40		265
Richfield Springs	1,630	55		1,685
Saratoga Springs	4,300	360	325	4,985
Sharon Springs	1,680	270	645	2,595
Total	8,375	800	970	10,145

Clifton Springs an able staff of physicians is available to care for the patients. In the other places, the patients are advised to consult with one of the physicians in practice in the community, although this matter has not in any of them been made 100 per cent compulsory. At Saratoga Springs the State in its development of the spa has provided for medical direction of the work, as well as for the initiation of a program of study and investigation. In addition to full-time administrative medical direction, the physicians in practice constitute the voluntary medical staff of the spa and assist in the care of the welfare patients. Both Sharon Springs and Richfield Springs have medical directors who, in addition to their regular private practice, advise the management in problems of medical administration.

This gives you a quick survey of the spas of New York State, which, with the possible exception of California, has a greater variety of mineral waters than any state in the Union. New York State is without a doubt the leader in the development of its mineral water resources for therapeutic use.

In case of an emergency it is important to know the possibilities for the proper housing and care of patients. A list of the available accommodations has been assembled from the printed material of the different spas and from the *Red Book* of the American Hotel Association. Table 1 lists this information and shows the number of rooms available in hotels containing thirty or more rooms each; the number in pensions, which provide meals, containing thirty rooms or less; and, from

THE ROLE OF SPAS IN MEDICAL PREPAREDNESS

A Survey of the Accommodations Available at the Six Spas in New York State

WALTER S. McCLELLAN, M.D., Saratoga Springs, New York

THE stress on preparedness emphasizes the importance of the information made available in a recent survey of the facilities and accommodations for the care of patients in the spas of New York State. This survey revealed that it is possible to care for at least 10,000 patients at one time, approximately one-half of whom can be accommodated at the Saratoga Spa. The data obtained from this survey are presented in the present communication.

Preparedness is before us continually day and night. We are asked to prepare for the possibility of war and for the support of others who are at war, prepare our men for service in the army, and prepare ourselves for any national emergency. Parran¹ in an address in 1940 presented this problem dramatically. He discussed the requisites for building up national strength and stressed the fact that even though every attention is given to the building up of large reserves of raw material, the construction of a large amount of mechanized equipment for army use, the stocking of the same with ammunition, and the building of ships—all of this would be of little value unless the man power of America were sufficiently fit, unless they were free from preventable disease, and unless their moral and mental stamina were able to withstand the increased stress and strain of the emergency. He emphasized that all of these features of physical fitness are important in the days of peace when everything is calm but that they are urgent now that the people must be "physically tough, mentally strong, and morally sound."

With this challenge before the American people to do all in their power to maintain physical fitness as one of the important phases of medical preparedness, it is my purpose to consider for a short time the part that our natural resources, as utilized in the spas of this country, may play in this direction. A glance at the reports from Europe indicates that in all of the war-torn countries the importance of the spa is recognized and that every effort is

made to utilize these resources in the face of their tremendous emergencies.

Schnelle² has recently discussed the types of baths available in the German spas for the treatment of joint injuries and infections such as arise frequently from war injuries. He points out that the mineral baths with low mineral content are the mildest stimulus to healing. Warm brine baths represent the second grade of stimulation. Then the use of warm sulfur waters is a third step, while the moor and mud baths provide the greatest stimulus in treatment. In his discussion he touched particularly on the use of the underwater treatment in various forms of articular stiffening and in some forms of paralysis. He also recommended the use of carbon dioxide gas for poorly healing wounds of the lower extremities, decubital ulcers, and burns. In this treatment he places the extremities in a box where the air is warmed with incandescent lamps and then introduces the carbon dioxide into the box under high pressure. He states that this cools the air and that the carbon dioxide in the chamber acts on the wounded tissues. He says that this is not of value in the treatment of varicose ulcers.

It is reported that the German Army Staff have a regular program developed where they send the soldiers from line duty for a furlough period at different spas. This program is used as a conditioning period to keep their fighting men in every way physically fit. Their regular and extensive application of spa treatment in World War I is a matter of record.

In France, as is indicated by the report of Mougeot,³ they are utilizing the spas in the treatment of many conditions resulting from war. He stresses particularly the value of the carbon dioxide baths at Royat in the treatment of the unstable heart and the heart that is forced by exertion beyond its reserve. Villaret⁴ has recently discussed the organization and plan that has been developed by the Commission on Mineral Waters in France to care for the war wounded in the various hydro-mineral and climatic stations.

In a recent news note,⁵ it is evident that the British spas are being utilized to a greater extent by those suffering from chronic conditions. They state that there is not a single complaint that can be relieved by Continental

RECENT ADVANCES IN BACILLARY DYSENTERY*

JOSEPH FELSEN, M.D., New York City

RENEWED interest in bacillary dysentery is of particular significance at this time because the disease has always been a recognized major military hazard. A feeling of almost complete apathy which existed in 1932 has been dispelled by epidemiologic, laboratory, and clinical studies during the past eight years. With this increasing knowledge there has been a rather astounding rise in the reported incidence of bacillary dysentery in the United States from 625 cases in 1933 to 19,152 in 1940. At the same time there occurred a decline in the unclassified diarrheas from 17,042 in 1933 to 1,484 in 1940.¹

The obvious inference is that when infectious diarrheas are carefully investigated, the majority appear to be bacillary dysentery. The present communication is concerned with the more recent advances in our knowledge of this disease (Table 1).

1. *Bacteriologic Types.*—(a) *The Toxicity of B. alcalescens.* The time-honored classification into the nonmannite fermenters (Shiga, Schmitz) and mannite fermenters (Flexner V-W-X-Y-Z, Sonne-Duval, Newcastle, Alkalescens) bears no consistent relationship to the degree of pathogenicity. Since 1933 we have noted the increasing severity of Sonne-Duval infections, originally regarded as comparatively innocuous. Numerous instances of sudden deaths have been reported, particularly in children. *B. alcalescens*, described by Andrewes in 1918 as of doubtful pathogenicity, has been quite definitely proved to be pathogenic. Most of the reports concern urinary-tract infections but more recently they include intestinal infections, particularly in children. To these we have added 3 cases of acute bacillary dysentery in adults, 1 case of distal (regional) ileitis and 7 cases of chronic ulcerative colitis due to *B. alcalescens*.² Gilbert and Coleman³ report that 1 per cent of all fecal specimens cultured at the New York State Department of Health reveal *B. alcalescens*. Similarly, fecal examinations at the New York City Department of

Health in recent years have frequently shown the same organism. These specimens were obviously submitted because of the suspected presence of intestinal infection. In our control series of 4,770 cultures at the Bronx Hospital from April, 1937, to October, 1940, covering the monthly fecal cultures of food-handlers and nursing and medical personnel, only 3 instances of positive *B. alcalescens* cultures were encountered. All occurred in nurses within a period of a few weeks when a rising incidence of similar infections appeared in New York City, judging from the increased number of cultures received by us from the Department of Health through the kind cooperation of Dr. Ralph Muckenfuss.

Since our routine fecal cultures on hospital personnel represent many repeated examinations on the same individuals over a period of years, as well as on newcomers, the absence of *B. alcalescens* from the intestines of healthy individuals is significant. As recently pointed out in the Flexner and Sonne-Duval infections, there are undoubtedly some carriers but in most instances either the presence of active disease can be demonstrated by sigmoidoscopy or a history may be elicited of previous dysenteric symptoms. In other cases additional evidence may be obtained by absorption tests. Neter⁴ has shown that *B. alcalescens* contains two antigenic fractions, one identical with the Flexner organism, the other type specific. In a recent study of 35 strains of *B. alcalescens* we found that the M.L.D. for white mice averaged 0.05 cc. of an eighteen-hour broth culture. While considerable variation in toxicity was noted, a few strains being nonpathogenic, some exhibited marked constancy over a period of many months without being enhanced by animal passage. Generally speaking, our *alcalescens* strains were one-fifth as toxic as Flexner 21 used in our previous experiments on active and passive prophylactic immunization.

2. *New Clinical Forms.*—Seven new clinical types of the disease have been reported since 1933. It is of more than passing interest that the typical fulminating cases of acute bacillary dysentery described by Hippocrates in his "Epidemion" are the exception rather than the rule in modern medical practice. Even in our own time, Shiga dysentery

* Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

² The studies reported in this paper were carried out under a grant-in-aid from the S. A. Schonbrunn Research Fund.

³ Director of Laboratories and Research, the Bronx Hospital, New York City.

the records of Sharon Springs and Saratoga, some indication of the rooming facilities that are available without meals.

The figures for the number of guests which can be accommodated have been estimated from the reported number of rooms by considering that 50 per cent of the rooms are double rooms. Hotel managers advise that this is a conservative estimate and say that in many hotels 75 per cent of the rooms can be utilized for two people.

From Table 1 it can be seen that accommodations for patients in these places vary from approximately 160 at Alden to approximately 5,000 at Saratoga Springs. The survey reveals that over 10,000 patients can be accommodated at the six spas in the State of New York with the facilities available at the present time. These facilities, of course, differ in the nature and luxuries of the hotel or pension, but there are accommodations to care for the most modest, as well as the most fastidious, at the various spas. In Clifton Springs the hospital-sanitarium arrangement offers the most complete nursing and supervising care of any of the institutions.

The type of treatment available at the spa is particularly fitted to the needs of many patients, as is evident in the care of the "shell-shocked" soldier or the "bomb-shocked" civilian who, at the spas, will benefit from the hydrotherapeutic program combined with competent medical care. Also, there is often great need for a convalescent center to which the patients may be sent from the hospital for building up after their acute emergency has been treated. The spas offer a real solution for this problem.

The facilities available in the spas of New York State offer a real possibility for use in the face of any national emergency. Surveys are being made of the number of physicians available for service, of the nursing personnel, and of the hospitals of our country. We recognize that the use of our hospitals must also continue for the civilian population. In our spas we have accommodations for the care of military or civilian patients in any emergency, which are not utilized generally throughout the entire year. It is true that a certain proportion of the facilities listed above are not suitable for year-round operation. In some, considerable alterations would be necessary. However, there are many available which could be utilized 100 per cent for the care and treatment of patients sent either from the army or from the civilian population in the face of actual war. These facilities

should not be neglected in any survey for medical preparedness.

Summary

Some data regarding the facilities available in the spas of New York State are presented. It is evident that there are extensive accommodations at hand for the care of many patients. The spas offer also the utilization of natural resources that have not been widely applied even in peace times in this country.

From the interest shown in the spas of Europe, it is clear that they have a place in the care and treatment of soldiers on furlough, as well as of war casualties.

Adequate medical personnel who could direct this program is already available at nearly all the spas.

Medical preparedness does not alone pertain to the health or treatment of disease in our colleagues in military service. It must include a consideration of what can be done for our entire population living and working under increased conditions of speed and stress. Particularly, it will apply to the worker in industry, transportation, or other lines, or to the executive in charge of these branches. It is important to keep them all in good health—yes, just as important as it is to have able-bodied soldiers. The spas of the State of New York can contribute in real measure to medical preparedness.

Discussion

Dr. Allen Holmes, *Penn Yan, New York*—May I thank Dr. McClellan for this timely presentation. Whether we know it or not, war is here. The spas are in a position to do a useful service. There are many chronic cases in the hospitals that could with benefit be transferred to the various resorts. This would relieve hospital congestion for more acute cases. There are many men now in service. Some of these, from time to time, could be benefited or restored to usefulness by a stay at one of the spas. Saratoga has unusual and extensive facilities. During the last war, the Jackson Health Resort was taken over and used by the government. However, insofar as is possible, I feel that the present personnel of the spas should be utilized with as little government complication as possible.

in chronic cases, the organisms can often be recovered by aspiration from the crypts of Lieberkühn where they retire for self-protection from the inimical flora of the intestinal tract. The sigmoidoscopic crypt aspiration-spray culture method is particularly useful for their recovery.³ We now use Endo and desoxycholate citrate agar plates routinely, supplemented wherever necessary by other differential media. Desoxycholate citrate agar inhibits the growth of some dysentery strains which grow freely on Endo agar, particularly after exposure to sulfonamide drugs. This may be modified, however, by the use of para-amino-benzoic acid,² which acts as a sulfonamide inhibitor. Thick seedings of fecal material are best made on the desoxycholate medium but thin inoculations on Endo agar give better results if the material cultured is obtained by aspiration of a clean mucosa which eliminates many nonpathogens that often prove so troublesome in fecal cultures. SS agar is also efficacious.

The survival of *B. dysenteriae* in the presence of *B. coli* "in vitro" is of some importance in understanding the variability of the period during which the former can be recovered from the intestine in acute bacillary dysentery.* In some cases the organisms disappear in a few days while in others they persist for months. In testing 10 strains of *B. coli* for their inhibitory or overgrowth effects, we found that some strains of *B. coli* had no restraining influence, *B. dysenteriae* Flexner being recovered without difficulty for at least a week from incubated broth culture mixtures of approximately 95 per cent of the former to 5 per cent of the latter. Conversely, some *B. coli* strains constituting only 5 per cent completely prevented the recovery after twenty-four hours of *B. dysenteriae* Flexner which made up approximately 95 per cent of the suspension. This "blotting out" phenomenon suggests marked differences among *B. coli* strains on the survival of *B. dysenteriae* which may account for the difficulty or ease of recovery from the intestinal tract. Phage effects and pH changes appear to play no part in the experiment cited. Therapeutic applications are being studied.

4. *The Use of Alcoholic Antigens for the Determination of Agglutinins.*¹⁰—In our earlier work it was deemed best to use eighteen-hour viable broth cultures for the quantitative estimation of serum agglutinins. In order to simplify and expedite this procedure for

military use under field service conditions, parallel tests were set up using eighteen-hour viable broth cultures, formalinized, acetone- and alcohol-killed antigens. The serums of 300 patients were tested including approximately one-fourth with diagnostic titers. While comparable results were obtained with all four antigens the alcoholic antigen appeared to be most consistent and stable, with the acetone antigen a close second. This stability has remained unimpaired for eighteen months at ice-box temperature. Our routine serologic setup now includes alcoholic antigens of *B. dysenteriae* Flexner V-W-X-Y-Z, Sonne-Duval, Newcastle, Alkaescens, Shiga, and Schmitz. We wish to stress again the importance of a rising agglutination titer. A single diagnostic titer without confirmatory clinical, bacteriologic, and sigmoidoscopic evidence is of limited value, since it may be the result of a previous dysentery infection unrelated to the present condition.

5. *The Effect of Sulfonamide Drugs on the Growth of B. dysenteriae "in vitro."*—Saturated solutions in nutrient broth of sulfanilamide, sulfathiazole, sulfapyridine, neoprontosil, and sulfanilylguanidine failed to prevent completely the growth of *B. dysenteriae* Flexner (V-W-X-Y-Z), Sonne-Duval, Newcastle, Alkaescens, Shiga, and Schmitz after ten days' incubation. This limited bacteriostatic action of the sulfonamide drugs "in vitro" has been attributed by some investigators to the presence of peptone in the culture medium. The sulfonamide drugs appear to interfere with the nutritional requirements of susceptible bacteria, according to Lockwood and Lynch.¹¹ In the presence of sufficient peptone this bacteriostatic action is largely nullified. We have, however, also noted the same poor bacteriostatic action of the five drugs mentioned in saline suspensions of various *B. dysenteriae* strains. The most effective drug was sulfanilamide. The most resistant organisms were *B. shigae* and *B. alkaescens*. "In vivo" experiments seemed to parallel those in the test tube. Intra-peritoneal inoculations of eighteen-hour broth cultures of *B. alkaescens* #9 saturated with sulfonamide drugs failed to protect mice in almost all instances against 10 M.L.D. The same failure to protect also occurred with saline suspensions of *B. alkaescens* #9 saturated with sulfonamide drugs.

The following points may be of interest in evaluating the usefulness of the sulfonamide drugs: (1) We have noted hemorrhagic necrosis of the colon in patients treated for

* I wish to acknowledge the assistance of Miss Esther Levendron in the experimental studies.

TABLE 1

When cases of "diarrhea, dysentery, and enteritis" are studied, the majority appear to be bacillary dysentery.

appears to have been largely displaced by Flexner dysentery in most parts of the world, including the Orient. The clinical severity of the disease no longer depends on whether or not it is a Shiga infection. Many Sonne-Duval infections are most virulent while some Shiga dysenteries are relatively mild. Do these represent disease adaptations to a changed environment and climate? There is some evidence pointing in this direction.

These variations can hardly be explained on the basis of a natural or acquired immunity for the United States has presented an almost virgin field for the spread of bacillary dysentery. Climate is undoubtedly a factor, for aside from the general hygienic and sanitary factors operative in subtropical or tropical regions, the cooler plateaus are relatively free of the disease and patients recover more quickly when moved to these areas. Yet, bacillary dysentery has neither seasonal nor zonal limitations. Some of the worst epidemics have occurred in winter and Byrd's antarctic expedition was afflicted with Flexner dysentery. Thus, bacillary dysentery is often a paradoxical disease, insidious in onset and protean in its clinical manifestations. The asymptomatic, afebrile, and constipated types are generally discovered during

the course of epidemiologic surveys. These patients are not healthy carriers because they exhibit the characteristic progression of intestinal pathology, rising agglutination titers, and final disappearance of positive cultures. The appendicular, meningitic,⁵ pneumonic,⁶ and agranulocytoid⁷ types refer essentially to the confusing pictures seen at the onset of the disease. Unless these atypical forms are recognized they constitute potential sources of contagion. The clinical pictures are well defined and theoretically represent the effects of an admixture of at least two toxins. The enteric toxin is present from the onset but it does not dominate the clinical picture until the end of approximately twenty-four hours.

3. *The Laboratory Diagnosis of Acute Bacillary Dysentery.*—(a) *The survival of B. dysenteriae in the presence of B. coli.* We have previously stressed the diagnostic tetrad of positive fecal culture, rising agglutinin titer, positive phage and purulent character of the intestinal exudate. In the average case, particularly during the first week of the disease, the organism may be readily recovered from the mucopurulent material in the feces. In many instances, however, the dysentery organism has a very transitory existence, disappearing in two or three days. In these, as

(1) Immune rabbit serums protected white mice against 10 M.L.D. of *B. dysenteriae* Flexner for at least five days. No such protection was afforded if the serum was injected after the organisms. (2) The parenteral injection of phenolized vaccine afforded considerable protection against subsequent 10 M.L.D. of *B. dysenteriae* Flexner. The mortality of vaccinated mice was 20 per cent as against 90 per cent in the nonvaccinated group. (3) Type specificity and effective immunization appear to go hand in hand. (4) Rapid and effective active immunization against monovalent strains can be produced by the use of alcoholic antigens which are easily prepared. (5) Prophylactic or therapeutic serum can be quickly prepared in rabbits or man by the same method. (6) Active or passive prophylactic immunization has been successful in all types except *B. alkalescens* where the results thus far have been less satisfactory. (7) The use of polyvalent TPD (typhoid-paratyphoid-Flexner, V-W-X-Y-Z) alcoholic antigens in the proportions of 2:2:6 have proved equally effective against all three infections.

While supportive clinical data on the effectiveness of prophylactic immunization by vaccines and serum is at hand,¹⁶⁻²¹ the final evaluation of this method awaits large-scale field tests. It may prove particularly valuable in military work and has already been applied by Prigge in Germany.

INFANT MORTALITY IN ENGLAND AND GERMANY

The death rate of German babies in 1940 was still much higher than the infant mortality rate in England, comparing the figures for 126 English large towns with German towns having a population of over 100,000. The latter statistics, from the Reich's *Journal of Public Health*, which have now become available, give an infantile mortality rate during 1940 of 63 per one

thousand as against the English rate of 51. The German rate is the highest for the years 1936-40, for each of which it has been at least 10 per thousand higher than the English rate. In no one year since the Nazis came into power has the number of the *Herrenvolk's* surviving infants approached the English total.—*Medical Record*

TAIN'T CRICKET

"November 7th. Comes via Chamberlain the tale of the patient so earnestly sold by Bill Arnold's allergic survey which showed her sensitive to eggs that she returned the hen the grocer sent asking for a rooster instead."—*Random Thoughts of the Secretary, The Journal of the Arkansas Medical Society*

AN ITEMIZED ACCOUNT

Nutritionists have long insisted upon informative labeling of food products. Here's an example of the nth degree of informative labeling displayed in a restaurant: "Hard boiled egg—1 cent; wear and tear on chicken—3 cents; rooster's fee—1 cent; total cost—5 cents."—*Credit Lines, Am. Pub. Health*

infections not involving the intestinal tract. This possibility must be considered in treating an intestine which is already ulcerated. (2) Acute bacillary dysentery is essentially a self-limited disease, running its course in three to ten days without specific treatment. Babies often die from dehydration and acidosis rather than from toxemia due to the dysenteric infection. Supportive therapy alone, such as the use of nonspecific human serum or lyophile plasma, intravenous dextrose or Ringer's solution, will often enable these little patients to survive the critical first two or three days. (3) The absorption of sulfonamide drugs through denuded areas of mucosa is more rapid than through intact mucosa. The danger of toxic systemic manifestations is therefore correspondingly greater. (4) *B. dysenteriae* survive high concentrations of the sulfonamide drugs which have no effect on ulcers already produced. (5) "Inhibitors" which nullify the bacteriostatic action of the sulfonamide drugs are present in autolyzed tissue and culture filtrates of resistant bacteria. This explains the unsatisfactory action of these drugs in the presence of pus, and the intestinal exudate in bacillary dysentery is characteristically purulent. (6) Attention is directed to the bactericidal action against *B. dysenteriae* of gastric juice with pH of 5.5 to 4.5 or less.¹² The oral use of dilute hydrochloric acid or glutamic acid hydrochloride (acidulin) as a prophylactic is suggested. (7) We have not seen a case of chronic bacillary dysentery (chronic ulcerative colitis, distal ileitis) cured by the sulfonamide drugs.

(6) *The Pathogenesis of Chronic Ulcerative Colitis and Chronic Distal Ileitis.*—Confirmatory data regarding the common pathogenesis of bacillary dysentery, chronic ulcerative colitis, and distal (regional) ileitis has been received from many sources.*¹³

Much of the confusion surrounding these diseases has been due to the disinclination on the part of clinicians to make careful epidemiologic and sigmoidoscopic cultural studies. It is most important to secure data on the first attack. In a surprising number of instances this may be traced directly to a proved dysentery outbreak. The first attack is followed by a characteristic series of recur-

rences increasing in frequency and severity. The fully established disease of chronic ulcerative colitis or ileitis is consummated in about one year. The difficulties of recovering *B. dysenteriae* at this late date have been enumerated. The following table representing 289 cases of chronic distal ileitis, ulcerative colitis, and combined ileo-colitis demonstrates the value of careful bacteriologic investigation. It reveals an incidence of 15.0, 17.7, and 24.0 per cent, respectively, of positive dysentery cultures as compared with a control group of 0.08 per cent in the same area (Table 2).

TABLE 2.—POSITIVE CULTURES IN CHRONIC DISTAL ILEITIS, CHRONIC ULCERATIVE COLITIS AND COMBINED FORMS (289 CASES)

	Cases	Positive Cultures	Per Cent
Chronic distal ileitis	33	5	15.0
Chronic ulcerative colitis	231	41	17.7
Combined ileitis and colitis	25	6	24.0
Total	289	52	18.0

Failure to isolate *B. dysenteriae* or to elicit an epidemiologic history in every case is not significant. The patient may have forgotten the details or the initial attack may have been mild. Our experience in recent years confirms the detailed report of 1936 in which we presented evidence of the common pathogenesis of bacillary dysentery, chronic ulcerative colitis, and distal ileitis.¹⁴ We have succeeded in tracing these diseases in individual, previously healthy, patients from the initial stage of acute bacillary dysentery to the final chronic phase. They represent the perpetuation of stage 3 of acute bacillary dysentery (stage 1—punctate follicular hyperplasia; stage 2—punctate follicular necrosis; stage 3—discrete and confluent ulceration with superimposed nonspecific infection). The practical implication is that the ideal treatment of chronic ulcerative colitis and distal (regional) ileitis is the prevention of bacillary dysentery. The latter is completely preventable and its eradication should be followed by the disappearance of the two chronic forms of the disease.

7. *Prophylactic Immunization Against Bacillary Dysentery.*—There is considerable clinical evidence of an acquired immunity in bacillary dysentery.¹⁵ The subject of prophylactic immunization is of particular importance from a military point of view. Our experimental work has been concerned chiefly with the use of serums and parenteral vaccines. The details have been reported elsewhere and may be briefly summarized as follows:

*In follow-up studies of 334 cases of bacillary dysentery, Block and Greene report (Elgin Papers, Elgin State Hospital, vol. 3, p. 136, 1938) an incidence of 8 per cent of chronic ulcerative colitis. This figure closely approximates our findings in the Jersey City epidemic of 1934 (chronic ulcerative colitis 8.2 per cent; chronic distal ileitis 2.5 per cent).

community of Pantton crossed Lake Champlain on the ice and discovered by chance the natural beauties and agricultural promise of the valley of the Bouquet River.⁴ This was 10 miles inland from the lake extending in a southerly direction from the present site of Elizabethtown in Essex County, New York. Their enthusiasm inspired a small migration across the lake the following winter of 1792 to this "Pleasant Valley." They struggled inland over a narrow trail through deep snow without benefit of even a road for sleighs. They harvested a good yield of maple sugar, however, and prospered sufficiently through the year so that they were able to persuade their former physician in Pantton to cast his lot with them. He was Asa Post, then a young man of 27, who is reported to have come to Pantton from Saybrook, Connecticut, for the "cure of consumption."⁵ Post served the young community with satisfaction until 1800 when the arrival of a colleague in the person of Dr. Alexander Morse enabled him to retire to a farm in the valley where he died at the age of 92. He was the first physician to settle in the mountains.

Alexander Morse who followed him in Pleasant Valley served the mountain community for half a century. His saddlebags and blood-letting lance are preserved as mute witnesses of the rigors of early medicine there. In 1809 he was a delegate to the State Medical Society where he presented a paper on the "Effects of the High Altitude of Essex on Certain of the More Common Diseases." Hence, the mountain physicians lost little time presenting the advantages of climate and altitude in disease therapy.

A fringe of small communities grew up in the valleys of the northern and eastern Adirondacks in the fifty years after the coming of Dr. Post. Lumbering, iron mining, charcoal making, hunting, fishing, trapping, and farming occupied their rugged citizens. Gradually, medical pioneers moved in to make a hard life more bearable. Outstanding was F. J. d'Avignon, the second, who escaped to Au Sable Forks in 1837 under sentence of death for activities in inciting the Papineau Rebellion in lower Canada. F. J., the first, had come from Avignon in France to practice in lower Canada. His son's adventurous spirit could not be held there, however. F. J., the second, found in the Adirondacks freedom and the opportunity to practice a brilliant and enterprising type of medicine and surgery in which he readily excelled. His Gallic mannerisms and wit lent him an almost legendary

character, and his ability soon made him in demand far outside the confines of the Au Sable Valley. He traveled on horseback prepared to do his operating by lamplight on any kitchen table. County historians' mention his outstanding work as regimental surgeon in the Civil War and, then, begin to speak of F. J. d'Avignon, the third, who became as able and equally in demand. His team of spanking blacks and the improving roads connecting mountain communities enabled him to range over an even wider area than had his father. The dynasty continues with F. J., the fourth, who maintains today the colorful traditions of his family in his practice at Lake Placid.⁶

But more isolated communities were late in securing their own physicians and were long dependent upon doctors miles away or lucky to have the incidental advice of medical men who came to hunt or fish in their vicinity. When the invalid Trudeau decided to spend the winter of 1876 and 1877 in the "miserable hamlet" of Saranac Lake, he became its first resident physician.⁸ In 1880 a contemporary historian⁹ recorded that the 11 families in the Tupper Lake region were dependent for medical care upon doctors 30 miles away. Under such conditions, the layman's knowledge of medicine often reached high standards of practical application.

W. F. Martin, pioneer resort hotel proprietor of Saranac Lake,¹ was for many years on call to the sickbeds of the community. The winter of 1862 was unusually severe. His only daughter became seriously ill in March. A blizzard was raging and roads were practically impassable. The nearest doctor was 45 miles away at Keeseville, but as the child became worse Martin determined he must be obtained. He chose his most powerful horse and hitched him to a "pung"—a handmade, woodshod, low box sleigh. He put in an ax and a shovel and started to dig and plow himself through heartless miles of drifted snow where drifts were 10 to 12 feet high in narrow places. As he came to houses he made his errand known, and all the men turned out to help him dig, often going a mile or more until fresh help was volunteered. In this way he reached his destination with his powerful horse exhausted and unfit for the return trip. Without resting himself, he secured a fresh horse and started back with the doctor. The return journey was comparatively easy and swift, but the great effort was in vain as the child died just fifteen minutes before the doctor reached her bedside. The Adirondack

History of Medicine

The session on History of Medicine was created last year, and four papers were read at the Annual Meeting in Buffalo. The first two were published in the November 15, 1941, issue. —EDITOR.

ADIRONDACK MEDICINE

A Historical Outline

LEROY H. WARDNER, M.D., Saranac Lake, New York

OUTSTANDING pioneers of Adirondack medicine from René Goupil in 1642 to the elder Trudeau in 1873 came to the mountain region through the influence of ill health. They met there the characteristic hardships of the frontier. The health-giving benefits of its climate gained wide recognition in Trudeau's time and spurred the medical advances in the treatment of chest diseases for which the region is noted.

The Adirondacks are a group of mountains in northeastern New York, the most prominent feature of a region long unsurveyed and unmapped formerly known as "The Wilderness" or "Great North Woods." Their name was first loosely applied to the entire region until the State set definite boundaries to it in establishing the Adirondack Park. In it are contained all or a portion of ten counties of the State comprising a total area somewhat larger than the State of Connecticut.¹ It was the State's last frontier and the story of its medicine should consequently be of interest.

Ill health has powerfully influenced the lives of outstanding physicians in the history of the Adirondack region. Early in the fifteenth century it prevented René Goupil from taking the vows of the French Jesuit Order.² He was able to study the medical art, however, and his religious ardor brought him to New France as a Jesuit lay brother, perhaps a counterpart of the modern medical missionary. In August, 1642, he set out in a party with Father Joques to travel up the St. Lawrence from Quebec on a mission to the Huron Indians of the Great Lakes. They were ambushed by hostile bands of Iroquois just above what is now Three Rivers, Quebec; both Joques and Goupil were captured along with a number of friendly Hurons. Their captors then set out with them to the Iroquois

country through the watercourses of the Richelieu River and the Champlain Valley.

Torture was immediately their lot. They were beaten, their finger nails were torn off, and the savages chewed the raw quick with their teeth. Goupil retained composure through it all, ministering to the wounds of the other captives as best he could and even opening a vein for a sick Iroquois on the journey. Father Joques related that he bore himself with great humility and obedience, even to helping to paddle the canoe for his captors. Their route carried them by water through Lake Champlain and into Lake George skirting the boundaries of the present Adirondack Park. From Lake George their party followed an old trail near Saratoga to the Iroquois villages near the present site of Auriesville near Johnstown on the Mohawk River. Then the ordeal of torture increased. For six days they were exposed to the cruelty of all the village. After six weeks Goupil was dispatched by a blow on the head, thus gaining a martyr's death for the first physician to set foot within the Adirondacks. Father Joques was spared and later escaped to France with aid from the friendly Dutch at Fort Orange. His letters recording the martyrdom of Goupil are preserved in a volume of the *Jesuit Relations*.^{2,3}

History of the next century and a half leaves the Adirondack region relatively untouched. As the "dark and bloody ground," it was the private hunting preserve of the Iroquois, traversed only by occasional parties engaged in hunting or war. The Champlain Valley to the east saw the ebb and flow of Indian, French, and British fortunes through the Colonial wars and the Revolution, but the medical men of these armies came no nearer to the mountains than Goupil and they lacked such historians as Father Joques.

After the Revolution, as the urge for westward colonization became stronger, two adventurous spirits from the little Vermont

¹Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

Trudeau at Saranac Lake,¹ led no doubt by the obvious advantages of a post office and telegraph station in the midst of the wilderness. His first five winters there brought him continued good health, and the publications of Dr. Loomis and Marc Cook widened its fame as a health resort. The increasing number of patient-arrivals began to tax the village capacities, and the good doctor pondered the problem of care for those unfortunates who came with high hopes but inadequate means. His renewed interest in medical literature brought him by chance upon the theories of the German physician, Brehmer, who tentatively advocated the outdoor and institutional treatment of tuberculosis. Then, in 1882 Koch's epoch-making discovery of the tubercle bacillus fired him with great enthusiasm. He began at once fundamental experiments with the bacillus and, working in a laboratory heated by wood and lighted by kerosene, he succeeded in growing tubercle bacilli in a homemade thermostat for only the second time in this country. In 1884 wealthy friends supplied the capital and his guide friends bought land to make possible the humble beginnings of his inspiration, which has become the Trudeau Sanatorium of today.

The next decade saw almost unceasing labor accomplish great strides. A surprising number of scientific papers based on his laboratory studies came from his pen as he struggled to care for the ever increasing load of private patients, to supervise the administrative and medical problems of the growing sanatorium, and to solicit funds to make up the yearly deficits of the sanatorium and laboratory. The sanatorium treatment of tuberculosis proved successful and gained wide acceptance. This experience was plainly the inspiration for companion sanatoria of the region—Gabriels, Stony Wold, Ray Brook, and Sunmount. Through it all shone the lovable and sympathetic quality of his physicianship best exemplified by the maxim of which he was so fond: "To heal sometimes, to relieve often, to console always."²

To quote Donaldson: "Trudeau's was the first laboratory in this country devoted to original research in tuberculosis, and from it the doctor began to turn out work that was soon attracting attention all over the world. The experiments made and the papers written in Saranac Lake became the last word in tuberculosis. Gradually, the doctor gathered around him a growing group of younger men, imbued with his ideals and trained to his high standards of research and experimentation.

Under his guidance and inspiration they have done yeoman service in the great battle and achieved results that no man could have compassed singlehanded." Dean of the surviving group is Dr. Edward R. Baldwin, who came to Dr. Trudeau in 1892 to say that he had contracted tuberculosis and that he wished to come to the Sanatorium for cure and to study with him. When asked how he knew he had tuberculosis, he said he had used his microscope. Trudeau's *An Autobiography* remarks of this: "Truly Koch's teaching was beginning to bring practical results."³

By 1900 both the Sanatorium and the Laboratory were well established, and the good doctor delegated almost all the active duties to his assistants, although he continued his efforts to raise funds for their support until the last. He had frequent relapses of his old disease in his later years, but again and again he rose from his sickbed to continue. In 1910 he addressed the Congress of Physicians and Surgeons on "The Value of Optimism in Medicine." His paper quickly revealed itself as autobiographic and awakened wide attention. It was then learned that he had written it during a period of relapse when he awoke in the small hours each morning and needed some activity to relieve his mind from his own suffering.⁴

Dr. Trudeau died in 1915 in his sixty-seventh year. His friends and colleagues took immediate steps to preserve and expand the gains of his lifetime by forming the Trudeau Foundation. This serves as a governing and planning body for both the Saranac Laboratory and Trudeau Sanatorium. To these were shortly added a third project, the Trudeau School for Graduate Teaching in Tuberculosis, so that yearly several score of disciples of the "Beloved Physician" go forth to practice his teachings and humanity in all corners of the earth. His life had spanned an era in Adirondack medicine from backwoods practices to advances that won the continued admiration and attention of all in the field of tuberculosis. And with the passing of its greatest character this outline is properly closed.

historian Donaldson termed the effort "an *Erliking* ride of the North Woods—one of those tragedies of distance that bring home to us the epic hardships of the pioneers."

After the death of his little daughter, Martin was deeply impressed by the fact that it was largely due to the remoteness of the nearest physician.¹ Hoping to save himself or others from similar tragedy, he began reading medical books and seeking from medical men who stopped at his hotel fundamental instruction in the treatment of the most common diseases. The members of the profession were coming to the Adirondacks in increasing numbers for sport and recreation, and they recognized Martin's ability and the wisdom of his effort. Dr. J. Savage Delavan, of Albany, was his chief mentor on his spring and fall visits, but all gave him suggestions freely and furnished him with authoritative books, pamphlets, and even medicines. His fame as an amateur doctor quickly spread in a community where there was no regular one, and he was called to sickbeds over a radius of 10 miles about Saranac Lake until regular practitioners arrived in the early eighties.

Writers began early to attribute healing powers to the Adirondack climate. Dr. Morse's paper of 1809 has been mentioned previously. In 1857 Hammond's *Wild Northern Scenes*, a chronicle¹⁰ of a decade of mountain vacations, paid tribute to the tonic effect of the region. In 1869 a Boston clergyman, better known as "Adirondack Murray" for his *Adventures in the Wilderness or Camp Life in the Adirondacks*,¹¹ was widely criticized for his account of the tuberculous invalid who was brought into the mountains on a stretcher and improved sufficiently to walk six months later. Many invalids jumped at the unwarranted conclusion that Murray had said the Adirondacks would infallibly restore health in any stage of tuberculosis. Consequently, without an investigation or reasonable preparation they started for the wilderness and some of them died there. Winslow C. Watson,⁷ in his *History of Essex County* published in the same year, stated: "I have met with instances of individuals, who had reached their forest homes, in advanced stages of pulmonary affection, in whom the disease had been arrested, and the sufferer restored to comparative health."

The medical profession began to appreciate the advantages of climatic treatment in the next decade. In 1879 the well-known New York internist, Alfred L. Loomis, was able to address the annual meeting of the New York

State Medical Society on "The Adirondack Region as a Therapeutical Agent in the Treatment of Pulmonary Phthisis."¹² He recorded 20 tuberculous case histories of whom 10 had recovered, 6 were improved, and 4 were failures. One of these was the case of Dr. Edward L. Trudeau, whose enthusiastic and logically written letters setting forth the values of the "salubrious" climate were fully reproduced. "Not only in New York but all over the country, the doctors evinced a sudden enthusiasm respecting the Adirondacks that was obviously kindled by Dr. Loomis's torch," so wrote Marc Cook in his *Wilderness Cure* published in 1880.¹⁵ His was the first guidebook and curing manual for the tuberculous patient, and Cook freely admitted that the interest arising from Loomis's paper was the excuse for his book. By 1886 the concept of the mountain cure for chest diseases had so developed that Dr. Joseph W. Stickler, of Orange, New Jersey, wrote a book called *The Adirondacks as a Health Resort*¹³ containing numerous testimonials of doctors and patients on experiences concerning the Adirondacks. These form an authoritative record of early health seekers most of whose experiences were prior to 1880 and many to 1870.

Clearly the idea of the climatic treatment of tuberculosis in the Adirondacks did not arise with Dr. Trudeau, but it was he who demonstrated its effectiveness and, by controlled study, placed it on a rational basis. When he developed the disease at the outset of a promising New York City practice in 1871, he was sent to the South for treatment.¹ Later, as the disease progressed, he remembered good times on earlier hunting and fishing expeditions at Paul Smiths and asked to be taken there. He was quite literally brought in on a stretcher in the summer of 1873. He improved surprisingly in that summer but left the mountains in the winter only to return in much poorer condition in the spring. In the fall of 1874 he had improved so greatly that he determined to remain for the winter. The venture succeeded and he improved steadily all through that winter and the following summer. In the autumn of 1876 he moved to Saranac Lake for the winter thus beginning a custom of forty years. In the joy of returning health and vigor his old love of hunting and fishing asserted itself and the guides were quick to learn his excellence. While he made no effort to practice medicine actively, his services were often in demand and he gave of them freely to all.

A handful of invalids had preceded Dr.

all the last war in the British service, and has distinguished himself this winter, particularly in his attention to the smallpox patients and the wounded."

The result of this letter was that on April 11, 1777, Dr. Cochran was appointed Chief Physician and Surgeon General of the American Army. He served in this position for nearly four years, in charge of the field work of the Medical Corps of the Army. On January 17, 1781, he was again promoted to the position of director of the military hospitals of the United States with the rank of General. This, the highest position in the medical service, he held until the end of the war in 1783.

Considering the amount of territory covered by the armies of the United States extending from New England to the Mohawk valley, New Jersey, Pennsylvania, Virginia, and the Carolinas, the Medical Department was lamentably small. At the time of its reorganization in 1780 it consisted of one director of military hospitals in supreme command, one chief physician and surgeon general in charge of field work, three chief physicians and surgeons of the hospitals, a purveyor and an apothecary with their clerks, fifteen hospital physicians and surgeons, with twenty-six surgeon's mates. The rest of the medical corps, including clerks, matrons, stewards, storekeepers, nurses, and orderlies, numbered only fifty-seven. There were barely one hundred people to care for the sick and wounded over a battle front of over a thousand miles.

Not only was the personnel inadequate but the medical supplies were almost entirely lacking. In his letters that have been preserved, Dr. Cochran is constantly describing the terrible condition of the military hospitals. By the year 1780 the country was bankrupt; the value of its money had depreciated almost to the vanishing point. The Continental Congress was at its wits end as to how to procure funds for the maintenance of the army and was sublimely uninterested in the needs of the Medical Department. Requisitions for supplies were pigeonholed and completely ignored. By 1780, the hospital situation had become acute, and that Dr. Cochran had little hope of its improvement is shown by a letter written by him from Morristown to Jonathan Potts, purveyor of hospitals, on March 18, 1780:

"Dear Sir:

"I received your favor by Dr. Bond, and

am extremely sorry for the present situation of the Hospital finances. Our stores have all been expended for two weeks past, and not less than six hundred regimental sick and lame, most of whom require some assistance, which being withheld, are languishing and must suffer. I flatter myself you have no blame in this matter; but curses on him or them by whom this evil is produced. The vengeance of an offended Deity must overtake the miscreants sooner or later. It grieves my soul to see the poor, worthy brave fellows pine away for want of a few comforts, which they have dearly earned. I shall wait on His Excellency the Commander-in-Chief, and represent our situation, but I am persuaded it can have little effect, for what can he do? He may refer the matter to Congress, who will probably pow-wow over it awhile, and no more be heard of it. The few stores sent on by Dr. Bond in your absence have not yet arrived. I suppose owing to the badness of the roads. If they come, they will give us some relief for a few weeks."

In a letter written May 24, 1781, to Samuel Huntington, president of the Continental Congress, Dr. Cochran said: "The Hospitals are in the utmost distress for want of necessities for the sick. In some of them we have not stores, and in others the supplies are so trifling and insignificant as to be of little or no service. I am sensible of the difficulties and embarrassments of Congress, but am also sensible that unless some speedy and effectual measures are taken to relieve the sick, a number of the valuable soldiers in the American army will perish through want of necessities, who would soon be serving their country in the field could they be supplied. The surgeon who has the care of the hospital at Boston writes me that his sick are in great want, and that he is not in a situation to procure any relief. At Albany the only article of stores is about sixty gallons of vinegar, and the sick suffer extremely at times for want of provisions. The other Hospitals are in a similar condition."

On March 25 of the same year he wrote to Dr. Bond, the hospital purveyor: "I was favored with yours of the 20th of February, about fifteen days ago, on my way to Albany, which accounts for my not answering you until now—as I only returned last night. I am sorry to inform you that I found that Hospital entirely destitute of all kinds of stores, except a little vinegar, which was good for

GENERAL JOHN COCHRAN

T. WOOD CLARKE, M.D., Utica, New York

LEARNING against a circular mound in Forest Hill Cemetery in Utica are three stone slabs marking the location of the mortal remains that lie interred below. Two commemorate Colonel Benjamin Walker, aide to Baron Steuben and to General Washington, and his wife, while the third bears upon it the words: "Here lie the bodies of Dr. John Cochran, Director General of the Military Hospitals of the United States, and his wife Gertrude." It is seemly that the medical profession should know something of the story of this medical hero of the Revolutionary War whose remains lie in our state.

In 1570 John Cochran, a relative of the Earl of Dundonald, moved from Paisley, Scotland, to the north of Ireland. In the early part of the eighteenth century James Cochran, his descendant in the sixth generation, crossed the Atlantic and became an American farmer. James' third son, John Cochran, was born in Sadsbury, Pennsylvania, on September 1, 1730.

John Cochran, who early showed a disposition to go into one of the learned professions, was sent to a good grammar school and then took up the study of medicine in the office of Dr. Thompson, of Lancaster, Pennsylvania. Just as he finished his medical studies in 1755, the French and Indian War broke out. Since at that time medical education was largely empiric and such things as hospital internships were not obtainable, it was a common custom for young doctors to join the medical service of the army and obtain their practical experience on the ill or wounded soldiers. The young physician signed up as surgeon's mate in the British army and served through the entire war.

When in the summer of 1758 General Brad-

street made his famous expedition up the Mohawk valley across the carry at Rome through Oneida Lake, down the Oswego River, and across Lake Ontario to capture Fort Frontenac at the site of the present city of Kingston and turned the tide in the war, Dr. Cochran was a member of his medical corps. On this campaign he became a close friend of Major Philip Schuyler, of Albany, who, during the early days of the Revolution, as Major General, commanded the northern division of the American army until just before the battle of Saratoga. After the surrender of Canada, Dr. Cochran kept up his friendship with Philip Schuyler and on December 4, 1760, married his sister, Gertrude, at Albany. After that he moved to Brunswick, New Jersey, where his experience in the army, his conscientiousness, and his integrity soon made him one of the leading physicians in that state. In 1766 he was one of the founders of the New Jersey Medical Society and three years later became its president.

With the outbreak of the Revolution he attached himself to the Patriots' cause. In the late fall of 1776 he offered his services as a volunteer in the Medical Corps of the American Army. General Washington was not long in seeing that Dr. Cochran's talents were wasted in the position he held, and early in 1777 he sent the following letter to the Continental Congress: "I would take the liberty of mentioning a gentleman who I think highly deserving of notice, not only on account of his abilities, but for the very great assistance which he has afforded in the course of this winter, merely in the nature of a volunteer. This gentleman is Dr. John Cochran, well known to all the faculty. The place for which he is well fitted, and which would be most agreeable to him, is surgeon general of the middle department; in this line he served

legs, being all of a thickness, from his knees to his ankles, but that he had a fine gold coat." Dr. Cochran then comments that "a pretty representative the fellow will make to cause a rebellion to sink at his approach. I think from the description given of him he is much better calculated to cause an abortion in the fair sex than to quell a rebellion."

At the end of the war Dr. Cochran resigned from the army and, a short time after the peace, moved with his family to New York where he attended to the duties of his profession until the adoption of the new constitution, when his friend, President Washington, retaining—to use in his words—"a cheerful recollection of his past services," nominated him to the office of commissioner of loans for the State of New York. This office he held until a paralytic stroke disabled him in some measure from the discharge of its duties, upon which he gave in his resignation and retired to a home in the Mohawk Valley, a few miles east of St. Johnsville, where he terminated a long and useful life on the sixth day of April, 1807, in the seventy-seventh year of his age. He was buried near the old Cochran homestead still standing a short distance west of the Palatine Church.

His son, Major James Cochran, had married the daughter of General Philip Schuyler. General Schuyler, in 1772, had purchased a quarter interest in the Cosby Manor tract, where Utica now stands, and after his death in 1804 half of this became the property of his daughter, Mrs. James Cochran, and half of his other daughter, Mrs. Alexander Hamilton. In 1817, in order better to look after this property, the two sons, Major James Cochran and Captain Walter L. Cochran, moved to Utica and lived there for ten years. When they came to Utica the body of General Cochran was disinterred and reburied in the old burial ground on Potter Street. When this was abandoned it was transferred with military ceremonials to its present resting place in Forest Hill Cemetery.

By a strange coincidence the body of Dr. Augustus Burgoyne, the nephew of General John Burgoyne and surgeon general in his army, also lies in Oneida County. After the battle of Saratoga he was taken prisoner to Vermont, remained there after the war, and practiced his profession. He spent his last years at the home of his daughter, the wife of Dr. Zenas Bird, of Augusta, and on his death in 1824 was buried near Knoxboro.

SCIENCE IN 1941

The ten big science stories and achievements of 1941, selected by Watson Davis, director of Science Service, are:

1. The radio locator of attacking airplanes developed and put into war use.
2. The enrichment of white flour and bread with vitamins and minerals.
3. The "cure" of gray hair in humans by daily doses of one of the B vitamins, para-aminobenzoic acid.
4. The great aurora of Sept. 18.
5. The production of more and larger airplanes for war use.

6. The development of sulfadiazine spray treatment of burns.

7. Evidence that fowls constitute a reservoir for encephalitis or sleeping sickness and that mosquitoes carry the virus.

8. Evidence that infantile paralysis may be spread by flies.

9. Production of magnesium for airplanes by "mining" sea water.

10. Development and construction of a new type of cargo ship, Sea Otter II, welded and powered with auto engines.

"So you complain of finding sand in your soup?"

"Yes, sir."

"Did you join the Army to serve your country or complain about the soup?"

"To serve my country, sir—not to eat it."

—*The Highway Traveler*

Once Antigonus was told his son was ill, and he went to see him. At the door he met some young beauty. Going in, he sat down by the bed and took his son's pulse. "The fever," said Demetrius, "has just left me." "Oh, yes," replied the father, "I met it going out at the door."

—*Plutarch*

nothing—and frequently without bread or beef for many days—so that the doctor, under those circumstances, was obliged to permit such of the patients as could walk into town to beg provisions among the inhabitants. . . . I pity our distressed condition on the score of money, and unless a sufficiency can be procured at the opening of the campaign, we are undone.”

The lack of surgical dressings is well illustrated by the following request made by the purveyor: “Could you not, by advertisement, be able to procure a quantity of old linen from the good ladies of your city—I was obliged, after the last skirmish, when fifty men were wounded, to give every sheet I had in the world, but two, to make lint.”

How this small band of patriotic physicians carried on during the terrible years of deprivation is a source of amazement to us of the present day, used as we are to hospitals with comparatively unlimited resources. But they did carry on through hardship and through want, through filth and through hunger. The salary of the director general was only \$102 a month with \$60 for subsistence payable in Continental currency. The loss due to the depreciation of this money affected the medical officers but little, as these meager salaries were rarely paid. For two whole years not a member of the medical staff received a cent of pay, and they often went for days almost without food. In 1781 Congress, whose credit was by that time an imaginary quantity, adopted the plan of drawing on the various states for the salaries of the officers serving within its boundaries. The New York Legislature, while meeting the obligation of all other officers, made a distinction against those of the Medical Corps. By July, 1781, seven of the fifteen hospital surgeons had resigned. As three of the eight remaining were required for the three chief hospitals it left only five surgeons to take care of all the armies in the field. Pleas to Congress to promote certain of the surgeon's mates to fill the vacancies were ignored, with the result that the mates also began to resign in disgust.

At one time when Dr. Cochran learned that a former member of the medical staff was keeping certain supplies belonging to the government at Danbury, Connecticut, and he told the assistant purveyor at Fishkill to get them, he was informed that the latter had not sufficient funds to make the journey. He had to supply money from his depleted personal purse to make the trip possible.

In spite of these handicaps and hardships General Cochran struggled on doing all in his power to alleviate the physical and mental suffering of the sick and wounded under his care. That he cared for the souls, as well as the bodies, of his soldiers is shown by his appeal to the government to supply a chaplain to each hospital.

During the last two years of his service Dr. Cochran's difficulties were lightened. The surrender of Cornwallis stopped most of the active fighting, and the flow of fresh wounded into the hospitals decreased. By this time, too, aid from France was running smoothly and considerable quantities of medical supplies were arriving from our transatlantic allies. By the end of the war, due to the French aid and Dr. Cochran's untiring efforts, adequate medical care was being given to the Patriot troops.

Dr. Cochran was a man of stately presence and fair complexion with an expression to indicate genial and benevolent qualities. The volunteer surgeon's mate of the French and Indian War rose to the position of director general of the military hospitals of the United States by superior expertness in the duties confided to him and greater alacrity in their performance. An unusual personal modesty made his promotions unsolicited. In fact, when the position of director general became vacant, he strenuously urged upon Congress the appointment of the man next below him in his stead. The hardships and suffering he underwent were lamented only as they interfered with the service. He exhausted his personal credit by giving his all to the care of his charges. The last sheets from his bed were converted into bandages. A glowing humanity intensified his attention to the sick, and with an executive capacity, as thorough as rare, he was the author of many reforms in the army. He was the support of the languishing medical department.

That he was not lacking in a sense of humor is shown by a letter written in 1781 to Dr. Craik. Prince William Henry, later King William IV, had come to New York as a midshipman with the British fleet. A lad who had come from the city had seen the Prince, and Dr. Cochran related his description in these words: “He was asked what he was like and what he thought of him. He said he expected to have seen something more in him than in other people, but was disappointed except his being the ugliest person he ever saw, with a very large nose. His eyes resembled those of a wall-eyed horse, and his

tremely efficacious as wet dressings in the healing of the superficial pustular lesions of pyoderma. Satisfactory results have been obtained in 26 cases of extensive secondarily infected pediculosis corporis or scabies. Employed as an early wet dressing, improvement was noted in 8 cases of infectious eczematoid dermatitis. It is emphasized that, as a rule, when the superficial infection has been cleared up other treatments must be applied.

Localized pyogenic ulcerations and erosions as mild impetigos have responded to local applications of the solution diluted 1 to 3. The lesions have to be cleaned and the crusts removed by the usual methods. Cases that did not respond favorably to higher dilutions improved when a 1 to 3 solution was applied three times a day. Such strength is not recommended for wide areas. As a bentonite lotion it gave satisfactory results in 12 mild cases of impetigo and in 5 severe ones. When wet dressings are used, strict supervision should be exercised so that they are not allowed to dry.

It is worthy of note that a commendable and little known application of the solution is attained when it is used 1:80 in the form of a warm tub bath. The patient is allowed to remain in the bath from ten to thirty minutes. This procedure was tried in 6 cases of pemphigus, and all observers have remarked about the deodorant and cleansing qualities of the bath. The patients themselves have requested Dalibour's bath in preference to the commonly used potassium permanganate, over which it has also the advantage that it does not stain the bath tub. It is not to be taken for granted, of course, that it is at all advocated as a cure for pemphigus. Its astringent, deodorant, and antiseptic properties simply help to make the patient more comfortable. Such baths have also been used as an aid in several cases of exfoliating dermatitis, in generalized bullous eruptions, and in extensive pustular dermatitis with gratifying results.

We have also used this solution as a deodorant, with satisfactory results, in such diseases as granuloma inguinale, condyloma acuminatum, and severe malignancies. Dilutions of 1:10 to 1:20 are advised for this purpose. These dilutions can be recommended too for hyperhidrosis and bromidrosis.

In cases such as dermatophytosis, hypostatic dermatitis, and dermatitis venenata, when superficial secondary infection demanded immediate attention, dilutions varying from 1:8 to 1:30 were applied as wet dressings or

compresses in more than 200 patients. When the infection subsided in the course of a few days, the treatment was changed, the selection of the pharmaceutical agent depending upon the stage of inflammation of the skin and the particular sensitivity of the patient.

Dalibour's water, however, has not been found to be so good an astringent as Burow's solution in noninfected dermatitis venenatas or eczemas, nor did it improve cases of generalized moniliasis. It has not aided deep-seated pustular eruptions, such as sycosis vulgaris, pustular psoriasis, or furunculosis. We have found that in deep-seated pustular eruptions of the hands and feet Dalibour's water is not so rapidly effectual as $\frac{1}{4}$ per cent solutions of silver nitrate, but the prolonged use of it is less hazardous.

Prior to using this remedy, we patch-tested 25 patients with solutions of 1 per cent copper sulfate, 1 per cent zinc sulfate, and 1 per cent saffranine. No immediate or delayed reaction was observed. We have not noticed a single case of dermatitis venenata due to the application of the solution in over 400 cases in which it has been used, properly diluted in one form or another.

Summary and Conclusions

Dalibour's water has been found to be of value in several pyogenic conditions of the skin, tried in over 400 cases. Various methods of use have been discussed, and the incorporation of the components of the solution in new ointment bases has been suggested. The value of the solution used in the form of a bath is emphasized.

No intolerance was noted when properly diluted. Patch tests with the components of the solution always gave negative results.

The deodorant action of the solution has been emphasized.

It is of particular value in pyogenic infections presenting intolerance to other antiseptic preparations.

We believe that Dalibour's water deserves a more widespread use.

DALIBOUR'S WATER—ITS USES IN DERMATOLOGY

TIMOTHY J. RIORDAN, M.D., ORLANDO CANIZARES, M.D., and
GEORGE EDWARD MORRIS, M.D., New York City

FOR more than two centuries Dalibour's water, a weak solution of copper sulfate and zinc sulfate, has been used by the French school of dermatologists in the treatment of traumatic wounds and pyogenic infections of the skin. An extremely useful preparation with a fascinating history, it has withstood the test of time and, since it is not well known in this country, we wish to present our experience with its use for several different skin conditions.

Sabouraud³ claimed that the originator of this solution was named Auilleboust, sometimes also called Alibour, physician of King Henry IV, but according to Sezary¹ the real originator of this solution was Jacques Dalibour, a surgeon of the army of Louis XIV and member of the Royal Academy of Surgery.

Dalibour first used his famous solution in the year 1700 in the treatment of wounds of soldiers in the army of Louis XIV. At his death in 1735, Jacques Dalibour passed the secret formula on to his son, also a military surgeon, who in turn entrusted it to his daughter. The latter passed it on to her son, a druggist, who exploited it to its fullest under the name of "L'eau de merveille" (the marvelous water) and "L'eau souveraine" (sovereign water).

The name Dalibour has been spelled in many different ways such as D'Alibour (very commonly used), D'Alibourst, or D'Alibourt. But in all official papers in which the name of the originator of this solution was mentioned the name Dalibour was used. The last edition of the *French Pharmacopoeia* has reaffirmed the correct spelling as being "Dalibour," and it is hoped that this spelling will be carried in the English literature.

The Dalibour family kept the formula secret for many years; it was first revealed in 1812 in the *Formulaire Magistrale*, some 77 years after the death of Jacques Dalibour.

The original formula employed was: copper sulfate, 0.1 per cent; zinc sulfate, 0.4 per cent; camphor water, 1 per cent; safranine,

0.1 per cent; and distilled water (q.s.). The solution is pink in color, due to the presence of safranine, odorless, and clear. It has a mild, astringent, metallic taste. The pH of a 1:20 solution with distilled water is 5.3; with tap water, 6.3.

Of course, it was to be expected that many would try to modify and improve Dalibour's original formula. Some have suggested omitting the safranine, the solution thus prepared having a pale blue color due to the copper sulfate. Others have increased the strength of one or both of the contained electrolytes which are weakly present in the original formula. Dyes, such as gentian violet and brilliant green, substitutes for the safranine, have been found to have the advantage of a drying antiseptic action besides changing the color of the solution. The addition of 1 per cent or less of picric acid seems to be highly recommended in some South American dermatologic centers.² Thibierge³ added sodium chloride, 7 per cent, to make the solution isotonic with the blood. The *French Pharmacopoeia* gives two formulas of the Dalibour's solution: the weak, the original formula, to be diluted in two or three parts of water; the strong, which contains 1 per cent of copper sulfate, 3.5 per cent of zinc sulfate, and 10 per cent of camphor water to be used in higher dilutions.

It is not to be thought, however, that Dalibour's formula can be used only in the form of wet dressings or compresses, for it can be readily incorporated in such widely used preparations as Lassar's paste, lanolin, bentonite paste, aquaphor, or any other hydrophilic ointment base.

Some suggested formulas are: copper sulfate, 0.04; zinc sulfate, 0.16; distilled water, 6; lanolin, 10; zinc oxide, 4; petrolatum (q.s.), 30; or copper sulfate, 0.02; zinc sulfate, 0.06; glycerin, 4; aqua Hamamelis, 30; orange flower water (q.s.), 120. A preparation recommended for indolent leg ulcers is: copper sulfate, 0.03; zinc sulfate, 0.12; bentonite, 7; water (q.s.), 120.

During the past two years we have used Dalibour's water in many varied conditions in the dermatologic wards, in the clinic of Bellevue Hospital, and in private practice.

Diluted 1:20 it has been found to be ex-

TACHYCARDIA IN THE NEWBORN

HERMAN TARNOWER, M.D., F.A.C.P., and BERTON LATTIN, M.D., Scarsdale, New York

A REVIEW of the literature would indicate that paroxysmal tachycardia in infants is rare. This is probably the case but, like many uncommon medical conditions, when borne in mind it is apt to present itself with unexpected frequency.

As far as we were able to discover, no one person has had any wide or intensive experience with this condition (paroxysmal tachycardia in infants). In consequence, the treatment is far from standardized. Even in adults, as anyone who has seen a number of these arrhythmias knows, it is often necessary to try a few drugs before the desired effect is procured.

In infants the tachycardias of auricular origin are the most common, with auricular flutter and atrioventricular nodal tachycardia occurring next in frequency.^{4, 6, 9, 17, 19} While auricular fibrillation is fairly common in adults, it must be extremely rare in infants, since we have been able to find but 1 case reported in the literature.¹¹ The tachycardias of ventricular origin are uncommon and, as one would expect, the most serious.

We were fortunate to have the opportunity of seeing 1 case of auricular flutter and 1 of auriculoventricular nodal tachycardia. As events have turned, it was perhaps better that we were not confused by the wide divergence of opinion in the literature regarding therapeutics. In our innocence, we successfully employed the drug that theoretically appeared correct. Later we realized that the misgivings and fears we experienced were similar to those of others who have treated these infants.

The 2 cases we are presenting are unusual; nevertheless, the literature contains an exact duplicate of 1 and several instances of the other.

Case Reports

Case 1.—Dr. Jack Ehrlich, of White Plains, administered the usual prenatal care to the expectant mother, a well-nourished and well-developed white woman, aged 21. On March 11, 1939, in the eighth month of prenatal care, Dr. Ehrlich noted that the fetal heart was grossly irregular, with a rate ranging between 150 to 180. He followed the situation closely for one week and admitted the patient to the White Plains Hospital on March 19, 1939, for further consideration of the problem as to whether or not cesarean section should be performed. At this time the

mother's heart rate was 68, regular in force and rhythm. The fetal heart was grossly irregular in rhythm and the rate varied between 140 and 210. An attempt to take an intrauterine electrocardiogram was unsuccessful.

With the help of Dr. Studdiford the following reasoning was followed out. A coiling of the umbilical cord around the neck would be unlikely to give any trouble unless labor were in progress; a knot in the cord would produce a murmur as would most congenital cardiac defects and, since no evidence of premature placental separation presented itself, it was thought best not to anticipate it. Accordingly, it was concluded that the arrhythmia was inherent in the fetal heart and no further attempt was made to analyze it. Finally, it was thought that if the infant could not survive the trials of a normal delivery it might perhaps be better not to interfere with the law of nature in the "survival of the fittest."

The infant was delivered at full term on April 11, 1939, after twelve hours of labor, no instruments having been applied. The fetal rate during the second stage of labor varied between 130 and 180 and was grossly irregular. After delivery, physical examination of the baby (girl) was negative in every respect except that the cardiac irregularity persisted and the rate varied between 140 and 225. Pressure over the sinus caroticus caused a definite slowing of the heart rate. There were no murmurs. The birth weight was 8 pounds, 12 ounces. The placenta showed changes that were within normal limits.

An electrocardiogram was taken the first day of birth and showed auricular flutter with varying degrees of block. Digitalis, 2 minims every four hours, was started immediately. During the first twenty-four hours the infant lost 7 ounces. The nursing staff noted that the child's color was poor at times and that she regurgitated frequently. On the whole, the infant was never considered critically ill. On April 13, 1939, the third day after delivery, the condition was unchanged. At this time $\frac{1}{2}$ cat unit of digitalis was administered intramuscularly. Five hours later the heart rate was found to be 136, constant in force and rhythm; an electrocardiogram taken at this time showed a normal sinus rhythm with a peculiar second lead, which we think, in the light of subsequent electrocardiograms, was a digitalis effect. An x-ray of the heart was noncontributory.

The infant took her feedings poorly and remained below the normal expected weight. On discharge from the hospital on May 13, 1939, at the age of approximately 1 month, she was still 5 ounces below birth weight. The heart was examined frequently during this time and was al-

Presented at the Pediatric Section of The New York Academy of Medicine, April, 1940.

is new. The correct designation is new to me. I do not recall having ever seen or heard a historic review or clinical report on its use. In my own experience it always connotes Bockhardt's impetigo or osteofolliculitis. I use it regularly in this condition with almost invariably favorable results. I have never used it on any other occasion. Why, I cannot say. Probably it is because I think a well-prepared Burow's solution is better.

The logic of D'alibour's reasoning in compounding this solution is simple and clear. The local therapeutic value of copper sulfate and zinc sulfate was recognized by physicians many centuries before boric acid and aluminum acetate were known. Blue or Roman vitriol water in the fourteenth and fifteenth centuries was extolled as a local wet dressing in cutaneous inflammations and impetigo. The same may be said of white vitriol, which found its broadest use as a collyrium in inflammations of the con-

junctiva. Copper sulfate, in addition to possessing local stimulating and astringent properties, even in high dilutions is bacteriostatic and fungicidal.

Camphor is highly prized in the household as a local sedative. Aqua sedativa is an old item in the *National Formulary*, its antipruritic and sedative properties being dependent upon its camphor content. It has been recommended for use in herpes, erysipelas, pruritus, and eczema.

The simultaneous application of copper and zinc sulfates and camphor by means of D'alibour water affords us an effective bacteriostatic, astringent, and sedative solution for use as a wet compress.

It is mentioned in the older literature as a remedy in the treatment of chancroids, suppurating buboes, and purulent balanitis. I wonder whether it has been found superior to boric acid or Burow's solution for this purpose.

A HUMAN OSTRICH [a letter to the *British M. J.*]

"Sir—The following case is so out of the ordinary that I think its publication may be justified on that ground alone.

"A man aged 25 years was in prison, where he stated he had swallowed various articles. He was removed to a London hospital for x-ray examination, but at the hospital he managed to effect an escape, and was recaptured; in view of this behaviour it was thought necessary for him to be operated upon within prison walls. He was transferred to hospital on May 17, 1940. An x-ray examination made the same day showed (1) two long metal bodies and a big belt-buckle in the area of the stomach, (2) a screw in the right iliac fossa, (3) a long needle near the ileo-caecal junction.

"That evening I operated upon him under general anesthesia, opening the abdomen by a right paramedian incision. From the stomach I removed (1) a metal punch, (2) a spoon handle, (3) a tin prison-knife, (4) a buckle, (5) a piece of a metal comb, (6) a picture hook, (7) a piece of glass (this I had to work back from the duodenum through the pylorus). I found a needle lying partially through coils of small intestines and in the peritoneal cavity directly over the right iliac vessels. It appeared to have worked through the intestinal walls very easily. Later on he passed normally the screw which had been seen in the right iliac fossa. The third day after the operation, when he was left for a few minutes, he was found standing on his bed looking out of the window at the view. He made an uneventful physical recovery, but his mentality degenerated, and on June 8 he had to be certified insane, and

was transferred to a civil mental hospital, from which he escaped.

"On September 15, 1941, he was again in custody and admitted to prison with the history of having pushed a needle into his chest. There was a small scratch at the site of entrance internal to the left nipple. X-ray examination showed the needle lying to the left of the sternum in a slightly vertical line point downwards, and the lateral view showed it to be inside the thoracic cavity. I opened the chest with a horizontal incision over the sixth rib, and resected one and a half inches of this rib to open the pericardial cavity. Unfortunately the needle could not be found free in the cavity. The heart was beating strongly, and it appeared that the needle lay in the muscle wall; I did not feel justified in attempting its removal, especially as the anaesthetist was by then worried somewhat by the man's condition.

"On September 24 he passed four large pieces of glass per rectum, which did not injure him in any way. These he admitted swallowing about ten days previously in prison. He developed an empyema on October 13; I resected a part of rib and drained this: fortunately he made an uneventful recovery, the wounds being practically healed on October 30.

"The special points to be noticed are (1) that he could swallow large foreign bodies and (2) that he could pass glass fragments without any damage to himself.—I am, etc.,

J. W. McK. NICHOLL, M.D., B.Ch."

November 18

ways found to be normal. No medication was given from the time of the intramuscular digitalis. An electrocardiogram taken at 8 weeks of age was absolutely normal. The child was then taking her feedings well and weighed 10 pounds and 11 ounces. At present the child is 18 months old, weighs 23 pounds, and is apparently normal in all respects. There are no cardiac murmurs.

Case 2.—The second case occurred in an infant 10 days of age. She was the third daughter of an American-born white woman, aged 29. The first 2 daughters had been born abroad, 1 in Morocco and the other in Colombia, South America. They were healthy and normally developed.

The infant was a full-term girl delivered at the Lawrence Hospital on May 31, 1939, after a four-hour labor. Instrumentation was not necessary. The birth weight was 8 pounds, 2 ounces, and this was regained on the eighth day after the usual loss. A routine x-ray taken on the second day was reported normal. Dr. Follett, of Scarsdale, the pediatrician in attendance, had found the child to be normal on the ninth day. On the tenth day at the 10 A.M. feeding the nurse in charge found the infant pale, slightly cyanotic, listless, and cold. Dr. Follett was called immediately, and after a careful examination he concluded that the rapid heart was very likely primary rather than secondary to something else. This is certainly not an easy differential diagnosis to make (more will be made of this point later). An electrocardiogram was taken that evening and showed an atrioventricular nodal tachycardia at a rate of 256. The child looked critically ill, and it was felt that a heroic measure was justified. Accordingly, $\frac{1}{2}$ cat unit of digitalis was administered intramuscularly at 9:30 P.M. During the next hour and a half there was no change. At 2 A.M. the rate was 125, regular in force and rhythm. Clinically, the child had improved slightly. By morning she was normal, and an electrocardiogram showed a sinoauricular rhythm with a rate of 130. There was no electrocardiographic evidence of digitalis effect. A repeated x-ray of the chest was reported as showing a questionable thymus. On the sixteenth day, the day of discharge from the hospital, the infant weighed 8 pounds and 6 ounces. As far as is known there have been no recurrences. An electrocardiogram taken at the age of 5 months was normal. The child had developed normally. The family moved to Buenos Aires a few days after the last electrocardiogram was taken.

Discussion

These 2 cases bring many interesting points to mind. Are these episodes more frequent in infants than we have been led to believe? May they not be misdiagnosed and perhaps erroneously included in the vague groups of thymus and status lymphaticus death?

The clinical picture in our 2 cases was entirely different. Whereas the infant with nodal tachycardia showed evidence of severe circulatory disturbance, the one with auricular flutter was never critically ill. It is our opinion that nodal tachycardia in an infant is a much more serious affair than auricular flutter. Taran and Jennings²³ were impressed with this fact and wrote: "In cases of tachycardia of nodal origin an interference with ventricular filling may come into account. There is a real danger of a 'stopping effect.' Therefore, the stopping of a paroxysm of atrioventricular nodal tachycardia is an urgent measure."

Werley's²⁵ report of a fatal paroxysmal tachycardia in an infant 4 days old in whom the rate was 300 would indicate that these episodes are not to be taken lightly. Unfortunately, an electrocardiograph was not taken in this case. No medication had been administered. Autopsy showed a patent foramen ovale 7 mm. in diameter, and there was nothing else to explain the death.

Carr and McClure² reported a case of auricular flutter which was almost a facsimile of the one presented here. Their experience differed from ours in two respects. On the one hand, they were a bit more radical or conservative, depending on how you view the matter, in that the child was delivered by cesarean section. On the other hand, they were definitely more conservative and apparently justified in that they made no attempt to treat the auricular flutter, and this reverted to normal rhythm on the tenth day.

Sherman and Schless²¹ administered digitalis (4 drops of the tincture three times a day for eight days) to a 3-month-old infant with auricular flutter. The history suggested that the flutter had been present from birth. They felt the return to normal rhythm was the re-

FIG. 1. CASE 1. Electrocardiogram taken immediately after delivery. Auricular flutter with a block varying from 2:1 to 4:1. The auricular rate is 450. The ventricular rate is about 195. Right axis deviation.

FIG. 2. CASE 1. Electrocardiogram taken on the third day, five hours after intramuscular injection of $\frac{1}{2}$ cat unit of digitalis. Normal sinus rhythm at a rate of 135. Right axis deviation. The low T waves and the peculiar shape of the second lead may be digitalis effect.

FIG. 3. CASE 1. Electrocardiogram taken at the age of 3 weeks. The usual right axis deviation of infancy is present. The complexes are of a normal contour.

FIG. 3.

and that the administration of a single dose of digitalis, 10 grains, to a 3-year-old child even as an heroic measure, is not justified.

Aside from the tachycardias of ventricular origin, a fatal issue is most common where there is a concomitant anatomic congenital defect.²⁵ Auricular flutter occurs fairly frequently with a widely patent foramen ovale.^{1,23} There is no evidence of such a lesion in our case, but it is impossible to rule it out absolutely at this time. The youngster is being followed with this possibility in mind. Encephalitis,²⁵ diphtheria,¹⁶ and other acute infections have been associated with the onset of paroxysmal tachycardias. One can readily see how confused the issue may be in such circumstances.

There is another thought about which one might speculate. Would it be worthwhile to digitalize the mother in the event that one found the intrauterine fetal heart to have an irregularity similar to the one herein reported? There is precedent to show that this might be worth considering. Hyman,¹⁴ in 1930, made a phonocardiographic study of the fetal heart sounds and found that irregularities were not uncommon (9.2 per cent). He classified them into three types: (1) sinus arrhythmia, (2) extrasystoles, and (3) gross irregularities. His experience led him to believe that of the three types the gross irregularities were serious. In his 6 cases with gross irregularity, 1 aborted at the sixth month, 2 aborted at the seventh month, and 3 survived. Unfortunately, the cases are reported in summary, and it is impossible to know whether or not other factors were involved. It is, of course, equally possible that the irregularities were incited by an impending miscarriage, in which case digitalis or any other cardiac therapeutics would be unavailing.³

Summary and Conclusions

Two cases of paroxysmal tachycardia in the newborn, one of auricular flutter and the other of auriculoventricular nodal origin, are presented and discussed.*

The possibility of a paroxysmal tachycardia

should be considered in any instance where the cardiac rate is persistently rapid or irregular. Paroxysmal tachycardias in infants may occur more frequently than is commonly believed.

Though a great deal of investigation will be necessary before any therapeutic facts can be established, we feel that digitalis may be satisfactorily employed in the treatment of paroxysmal tachycardia of the newborn with a fair margin of safety.

* We recently saw a third case of paroxysmal tachycardia in an infant 8 days old. It was supraventricular in origin with a note of 265 per minute. The infant was not seriously ill so it was thought best to observe the progress for twenty-four hours before administering any therapy. Fortunately, the attack subsided spontaneously after eighteen hours.

AT ANY COST

"... Civilian defense will utilize additional time. Work previously performed by uterus and residents in the hospitals will be part of the attending physician's task."—*Advance proof*

of an editorial, "No Matter What the Cost," in the *Journal of the Michigan State Medical Society*. [In all fairness the mistake was corrected in the published issue—by scissors and paste.]

FIG. 4.

FIG. 5.

FIG. 4. CASE 2. Electrocardiogram taken during the acute attack at the age of 10 days shows an atrioventricular nodal tachycardia at a rate of 256.

FIG. 5. CASE 2. Electrocardiogram taken the following morning about twelve hours after the administration of digitalis shows a normal tracing with right axis deviation.

sult of a maturity of the conduction bundle tissue rather than digitalis effect.

Halbertsma and Hartog¹² were successful in reverting an auricular flutter of three years' duration to normal through the use of digitalis. The child was 2 years old when the flutter was first recognized.

In an article²⁴ published within the past two years the authors employed physostigmine salicylate, quinine, and pilocarpine nitrate in an infant 7 days old with auriculoventricular nodal tachycardia (280). The effects were alarming. In this same case there was an immediate and satisfactory response to intramuscular digitalis. A recurrence after circumcision also responded to this therapy, but this time one of the great fears of digitalis therapy was demonstrated—ventricular fibrillation was recorded. Fortunately, this was of a short duration and was immediately followed by a normal sinus rhythm. There were no further recurrences. The frank signs of cardiac decompensation which were present in this infant are not uncommon when the tachycardia has persisted for a few days, regardless of the type.

There are a number of reports of paroxysmal tachycardia that have been recurrent, starting and stopping spontaneously.^{8,13,15} Drug therapy in these has often shown little or no influence. One instance of the ventricular type¹⁸ masqueraded as idiopathic epilepsy for three years before its true nature was recognized. This same child died at the age of 8 during an attack, having experienced many seizures over a five-year period. Autopsy showed cardiac hypertrophy with vague myocardial changes. It is interesting that necropsy in another fatal ventricular tachycardia² in an infant aged 15 months also showed an unexplained cardiac hypertrophy.

Digitalis has been employed with varying degrees of success in the treatment of paroxysmal tachycardia in infants.^{7,10,11,14,16,21} No one has had the courage to advocate its use with any degree of emphasis. It is extremely difficult to draw conclusions from the literature of reported cases. One is apt to differ with the authors in the interpretation of the cardiographs or in the evaluation of the results obtained through the use of digitalis or other drugs. For instance, one case is reported²² as an auricular flutter in whom the use of digitalis resulted in a fatality, thus tending to discredit the use of digitalis in infants. On reviewing the case, however, one feels that perhaps it was a case of auriculoventricular nodal tachycardia rather than auricular flutter

The clinical improvement was remarkable. The temperature dropped from 103.4 to 100.4 F. at the end of twenty-four hours. The headache became less severe, nuchal rigidity almost entirely disappeared, and there was diminution in the Kernig's and Brudzinski's signs. The skin became suffused with a pinkish color probably due to the neoprontosil. For the next twenty-four hours 90 grains of sulfanilamide were given orally together with 30 cc. of specific serum intravenously. During the third day the same amount of sulfanilamide and 60 cc. of specific serum were given.

At the end of the third day of his illness the free sulfanilamide concentration of the blood was 9.5 mg. per hundred cubic centimeters. Further examination of the blood revealed 6,500,000 erythrocytes, with 8,950 leukocytes and only 63 per cent polymorphonuclear leukocytes. The patient had no complaints, was cooperative, and did not understand why it was necessary for him to remain in bed. The temperature varied between 98.6 and 100.2 F. On the fourth day a spinal tap revealed a clear and colorless spinal fluid under no increased pressure with a cell count of only 22 leukocytes per cubic millimeter, and no microorganisms were found either in direct smear or on culture. There was a concentration of 5.2 mg. per hundred cubic centimeters of free sulfanilamide in the spinal fluid. The patient now received 60 grains of sulfanilamide daily and over a period of four days ran a slight fever varying between 98.6 and 99.4 F. Another spinal fluid on the ninth day showed only 9 cells per cubic millimeter, with a free sulfanilamide concentration of 4.2 mg. per hundred cubic centimeters. The

patient was finally discharged feeling perfectly well, with no signs of residual injury.

Comment

The brilliant results of the use of sulfonamide derivatives and specific immune serum together in the treatment of acute meningococcal meningitis in its early stages are shown in the case recorded above. These results confirm the experimental results obtained by Brown⁵ and others in mice. We believe that this infection can be treated most effectively when these drugs and serum are administered according to the method used in this instance and that the results by this procedure indicate that the therapy of meningococcal meningitis has been simplified to the point where it can be used in the home with the most gratifying results yet obtained. There can be little question but that the intravenous administration of specific immune serum is far superior to any other mode of administration when combined with the chemotherapeutic agents now at hand. Thus, intrathecal therapy is not only unnecessary but definitely harmful.

BIRTH CERTIFICATES IN DEMAND

An appeal to all patriotic citizens not to apply for birth certificates unless there is a pressing need for them was made on January 30 by the New York State Department of Health in an effort to eliminate any delay in issuing certificates urgently needed as the result of the present war conditions.

Dr. J. V. DePorte, director of the Division of Vital Statistics of the Department, emphasized that unnecessary applications will seriously impede national defense. "The national emergency has suddenly made it necessary for millions of native-born Americans to produce acceptable proof of their citizenship and age," he said. "As a consequence, the New York State Department of Health has been overwhelmed with requests for copies of birth certificates or for the delayed registration of unrecorded births."

TUBERCULOSIS IN COLLEGE STUDENTS

The 248 colleges and universities having modern tuberculosis programs have abandoned the ancient concept of "consumption"—the advanced, serious, contagious, often hopeless stage of tuberculosis. They know early tuberculosis as a sneaking foe that can be discovered long before it causes actual illness. They know that the tuberculin test and the x-ray locate cases early, whereas to await symptoms and stethoscopic findings is to mark time until late manifestations occur. They know that tuberculosis remains the chief cause of death in the college age group. They know that at least one-quarter of American college students are infected, as shown by their positive tuberculin reactions.—Charles E. Lyght, M.D., Chairman, Tuberculosis Committee, American Student Health Association, in a letter to college presidents, 1941

Case Report

ACUTE MENINGOCOCCUS MENINGITIS NOW A SIMPLE THERAPEUTIC PROBLEM

HAROLD L. RAKOV, M.D., and J. SPOTTISWOOD TAYLOR, M.D., Kingston, New York

PRIOR to the use of specific serums in meningococcic meningitis, when the only therapeutic gesture of significance was spinal drainage, the mortality rate was 75 per cent. With the introduction of specific immune serums, administered both intravenously and intrathecally, this rate was reduced markedly to approximately 25 per cent. This therapeutic procedure was often laborious and time-consuming and required constant supervision by a physician trained in serum therapy. Particularly was this true when it became advisable to administer the serum into the cisterna magna or intraventricularly. Finally, Hoynes¹ in a large series of cases demonstrated that 84 per cent of the patients could be saved by giving the serum merely by the intravenous route.

The introduction of sulfanilamide as an effective therapeutic agent in meningococcic meningitis has further simplified the care of this disease. Recently, Schwentker² reported a series of 10 cases treated with sulfanilamide alone. He administered the drug orally, parenterally, and intrathecally with the result that 9 patients recovered. Waghstern³ also obtained better results with this drug alone than when it was combined with intrathecal serum therapy. Further, Long and Bliss⁴ demonstrated an even lower mortality rate when the intrathecal route of administration of sulfanilamide was discarded and the drug was given only by mouth. Finally, Brown⁵ and others showed experimentally in mice that sulfanilamide subcutaneously, combined with specific serum intraperitoneally, was more effective than either used without the other. In like fashion, we believe that sulfanilamide orally and specific serums intravenously constitute the most effective therapy yet found.

Of the sulfonamide derivatives, sulfanilamide seems to be the drug of choice, since it permeates the tissues more rapidly than neoprontosil. However, three or four hours are required for the absorption of the drug when given by mouth. Because of this, it is often advisable at the onset of therapy to administer neoprontosil intramuscularly in order that an effective concentration of one of these drugs in the blood and spinal fluid may be obtained promptly, but the oral administration of sulfanilamide thereafter will suffice. Concurrently, specific antimeningococcus serum intravenously should be used. With this regimen, spinal taps other than those for diagnostic purposes and control of

treatment are not required. Kolmer⁶ states that a concentration of 5 mg. per hundred cubic centimeters of free sulfanilamide in the spinal fluid should be maintained for at least three days.

Recently, we have had the opportunity of treating a case of acute meningococcic meningitis according to this latter procedure. The results were so striking that we feel a report of this single case should be made.

Case Report

S. S., a robust white man, aged 21, had been perfectly well until the afternoon of June 14, 1940, when he noted slight chilliness and asthenia while returning from his laborious work on a farm. He vomited that night. The following day he felt somewhat better until early afternoon when he consulted Dr. A. Feldshuh because of a severe bursting headache. He was sent immediately to the Kingston Hospital, and upon admission at 6:00 P.M. the patient was apathetic but restless, uncooperative, and talked only in monosyllables. His temperature was 103.4 F. Marked nuchal rigidity and Kernig's and Brudzinski's signs were noted. There was a faint roseolar eruption over the neck, anterior part of the chest, and arms. Trousseau's tache cérébrale was elicited, and there was slight right ophthalmoplegia.

Examination of the blood revealed 5,440,000 erythrocytes, 94 per cent hemoglobin (15.6 Gm. = 100 per cent), and 26,700 leukocytes, with 91 per cent polymorphonuclears per cubic millimeter. The spinal fluid was under increased pressure and cloudy, with 6,100 polymorphonuclear leukocytes per cubic millimeter, 32 mg. per hundred cubic centimeters of sugar, and 228 mg. per hundred cubic centimeters of protein. On direct smear of the spinal fluid there were observed intracellular gram-negative diplococci, which on culture proved to be meningococci. Blood cultures yielded no growth.

Upon the assumption that the gram-negative intracellular diplococci were meningococci, specific therapy was begun immediately. So at 7:30 that evening, he was given 20 grains of sulfanilamide orally, 30 cc. of neoprontosil intramuscularly, and 20 cc. of polyvalent antimeningococcus serum (New York State Department of Health) intravenously. Three hours later there were administered 15 grains of sulfanilamide orally, 20 cc. of neoprontosil intramuscularly, and 20 cc. of serum intravenously. This amount of sulfanilamide and neoprontosil was continued every three hours for six more doses, combined with three 20-cc. intravenous injections of the specific serum. Thus, within twenty-four hours the patient had received 125 grains of sulfanilamide orally, 170 cc. of 5 per cent neoprontosil intramuscularly, and 100 cc. of antimeningococcus serum intravenously.

From the Departments of Medicine and Pathology, Kingston Hospital.

Laboratory tests will usually yield no positive results at the onset. Sputum and gastric content studies usually are negative until the lesion breaks into the bronchiole. Sedimentation rate and blood cell changes generally remain unchanged for some time.

In short, our chief diagnostic aids are:

1. A meticulous history (study of family history, contacts, and individual history).

2. Properly taken x-rays of chest, perhaps in various positions (or perhaps with spot films of upper sections). A persistent abnormal shadow, particularly in the upper part of the thorax, is always suspected as being of tuberculous origin.

3. Repeated study of sputum and gastric washings and, perhaps, culture and guinea-pig studies.

4. Continued observation of the patient.

More often than not, the diagnosis of truly early pulmonary tuberculosis requires a period of observation of weeks, sometimes months, for the evaluation of clinical significance of the evidence. Continued observation is indicated so often in the minimal lesion not only for diagnosis but also for determination of the activity of the lesion. The minimal lesion is quite often not an early one when first discovered. In general practice previous x-rays are usually not available, and it remains to be determined whether or not the x-ray shadow represents an active and recent lesion requiring treatment. Observation should include chest x-rays taken every two weeks; weekly studies of sputum and, perhaps, of gastric contents; and continued temperature and weight records taken under proper rest and dietetic regimen, with perhaps repeated blood sedimentation rate and blood picture studies.

The principles of treatment.—We have only two therapeutic measures that when used in combination can be said to be effective in pulmonary tuberculosis—namely (1) general or constitutional rest, which should include that of both body and mind and (2) local pulmonary rest (collapse therapy).

While bed rest alone will cure certain tuberculous lesions (and by that is often implied strict confinement to bed with restriction of toilet privileges), yet mechanical collapse of the lung without bodily rest rarely does so. It is presumably preferable to have a tuberculous lesion heal by rest alone. Such healing is for the most part ultimately most secure and avoids the complications of pneumothorax therapy. Unfortunately, rest alone will not heal advanced lesions. Collapse therapy must be resorted to in most cases of advanced pul-

monary tuberculosis. The hazards accompanying collapse therapy are well appreciated. In short the principles of treatment are:

1. Strict bed rest should be used alone, at first, in all cases where there is reasonable hope that it will achieve the result, except for most pressing economic reasons in some special instances.

2. Collapse therapy should be resorted to only after bed rest has been given adequate clinical trial or where the character of the lesion is such that rest alone offers no hope of success or where collapse is required for the safety of the patient—namely, in case of hemorrhage or imminent danger of spread of disease.

3. In most cases before, during, and even after collapse therapy, an adequate period of bed rest is indicated to promote stabilization of the lesion at first and ultimate healing later.

Indications and procedures of collapse therapy should not be confined to the sphere of activity of the general practitioner; hence, they are outside the scope of this discussion. With the diagnosis established, the general practitioner is well advised to consult with a specialist as to the ultimate policy of treatment to be followed. Where collapse therapy has been decided upon, it is best for the patient that his treatment be at least temporarily carried out under guidance of a specialist or in an institution.

Management of the patient under rest is within the realm of the general practitioner. His is the responsibility for the decision whether rest treatment should be carried out at home, in an institution, or at a resort. He should be aware of all the social, economic, familial, and individual psychic factors that must be considered in such a decision. He should be familiar with all the circumstances that make it more desirable in one case to treat the patient at home, while in the other institutionalization will answer the purpose better, even though the medical indications of the lesion may, strictly speaking, be the same. If he is to undertake management of the rest regimen in the home of the patient, the general practitioner must know whether the home and all that it implies, as well as the patient, are suitable for it. Sending a tuberculous patient away from his home for treatment differs materially from hospitalization of patients with most other diseases. Much tact and psychologic handling is required on the part of the general practitioner.

The principles of rest treatment cannot be detailed here. It should begin with complete

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the May 1 issue and will concern "Treatment of Rheumatic Fever."

Treatment of Pulmonary Tuberculosis from the Standpoint of the General Practitioner

DR. CLAUDE A. FORKNER: The subject for our therapeutic conference this morning is the management of pulmonary tuberculosis from the standpoint of the general practitioner.

I think there is a widespread feeling among internists that they know how to manage and treat early tuberculosis. The best argument against that is the fact that our pulmonary clinics and our pulmonary wards are filled with the mistakes of the internists. So I think it is well worthwhile to have a discussion here of the management of early tuberculosis, particularly as it relates to the work of the general practitioner and internist.

Dr. Mayer will talk to us about twenty minutes on that subject and then we will open the meeting to general discussion.

DR. EDGAR MAYER: For the great majority of patients with chronic pulmonary tuberculosis, even those with advanced disease, there was a time in their illness when their lesion was so minimal that treatment was chiefly a matter of a few months' bed rest under the care of the general practitioner. The key problem, therefore, in chronic pulmonary tuberculosis is not how to treat the disease but rather how to discover it in time. There is no disease where the fate of the patient is more in the hands of the general practitioner. His understanding of the nature and potentialities determines more than anything else the ultimate results of treatment. Just as a truly early lesion is almost a guarantee of certain and prompt cure under proper management, inasmuch as approximately 96 per cent of early cases recover, so in the advanced cases, even with the most skilful management by pneumothorax, thoracoplasty, etc., the chances for recovery are little better than half. Since the mortality of untreated pulmonary tuberculosis is nearer 80 per cent, this is quite an achievement when we consider the number of patients in question.

It cannot be too often urged upon the gen-

eral practitioner that early diagnosis is all important for successful treatment. Even for the advanced lesion it may be said that treatment will be all the more effective the sooner it is begun. Therefore, just a few words about early diagnosis. First, the general practitioner must constantly have pulmonary tuberculosis in mind. He should consider it particularly when faced with certain complaints: (1) slight elevation of temperature, especially in late afternoon or evening, (2) weight loss, (3) fatigue, (4) recurrent "grippal attacks," (5) intermittent pains in the chest over long periods of time, (6) anorexia and indigestion otherwise unexplained, (7) slight recurrent cough with or without sputum, (8) blood streaking and hemoptysis.

The diagnosis of the early lesion, sometimes most difficult, is made by study of *symptoms*, *signs*, and *laboratory tests*. An early and even progressive pulmonary lesion may exist for some time without any *symptoms* whatsoever or with such as will pass unnoticed by most patients. Particularly often will there be no cough, expectoration, or fever. Occasional slight rises of temperature, clearing of throat, and swallowing of sputum frequently go unnoticed by most patients.

As to *signs*, the x-ray evidence of an early lesion may be overlooked, although the x-ray is our most important agent in diagnosis of the early minimal disease. The lesion may be hidden by other structures such as ribs, blood vessels, or the heart. It may be so small as to be missed, or its softness of shadow may prevent its recognition.

Abnormal physical signs are the last to be expected in the progress of an early lesion and will usually present themselves only when the lesion has extended to a bronchiole or to the pleura or is on the way to fibrosis. Absence of such physical signs should never exclude a diagnosis of pulmonary tuberculosis.

pulmonary tuberculosis come to pneumothorax treatment in a high proportion of cases. Collapse is indicated in the majority of these cases reaching an advanced stage and at an early phase usually as soon as there is evidence of stabilization.

In contrast, the majority of minimal lesions will not require collapse if discovered early and treated by bed rest. As this type of case is still a recent discovery, there is not yet available sufficient statistical experience over a longer period of observation. Data available now indicate that perhaps not more than 20 to 25 per cent of early minimal lesions progress to a stage where collapse becomes indicated or necessary for cure.

In the case of minimal tuberculosis found in practice, as I have already explained, it is not usually an early lesion but rather a fairly stabilized, if not an already arrested, lesion. Unless there is fairly persistent positive sputum, there is no indication for collapse therapy. The majority of these cases should be accessible to cure by rest treatment, although often economic considerations may determine the policy of treatment.

DR. GOLD: If pulmonary rest is really an important factor in curing pulmonary tuberculosis, why not use it in all of the early cases when the chances of securing collapse of the lung are always better than in much later cases? I am talking about artificial pneumothorax. Is it because it is too dangerous or is it because for some reason it is not effective enough?

DR. MAYER: A few years ago there was such a strong tendency for more and earlier pneumothorax treatment that for a time it looked as if someone would soon propose to collapse the lung to prevent development of lesions. The enthusiasm for early pneumothorax in minimal tuberculosis is dying down, I believe, for two reasons: (1) Pneumothorax is too serious, or, if you wish, too dangerous an intervention to be employed in the treatment of early minimal tuberculosis where the risk of such therapy is almost more than the risk implied in the disease. (2) Too often the end result of pneumothorax treatment is a fibrothorax with the loss by fibrosis of an entire lung and a severe functional handicap of displaced mediastinum, making the cure far worse than the disease.

I am among those who advocate increasing caution in the selection of cases for collapse and condemn indiscriminate collapse therapy for early minimal tuberculosis. As in all treatment, here, too, individualization is of

vital importance. In the light of the above, my answer would be that in the majority of cases of early minimal tuberculosis pneumothorax should not be carried out.

DR. C. H. WHEELER: I wonder if Dr. Mayer would say a word about the treatment or management of hemoptysis occurring in a patient with pulmonary tuberculosis? I wish you would answer particularly the question of whether or not such patients should be given morphine for suppression of the cough. This is a question about which there is a good deal of dispute.

DR. MAYER: Ordinarily, hemoptysis in a patient without a pulmonary cavity should give us little concern. Those with obvious cavity and those with nodes caseating through a bronchus are likely to have more serious hemorrhages.

The usual treatment of hemoptysis is immediate and strict bed rest with some sedation, not morphine, preferably a mild cough sedative such as codeine. Reassurance of the patient who is usually quite panicky is essential. There are other aids aside from pneumothorax—such as an ice bag applied to the chest, usually to the precordium; the sucking of ice; and perhaps the oral or intravenous use of calcium preparations. However, the use of calcium has for the most part been discarded. Coagulants such as thromboplastin have been used with little apparent success. Congo red given intravenously is likewise still uncertain in effect. Hypertonic saline given intravenously is also of questionable value. More important is the posture of the patient in its effect upon hemoptysis. It is best to have the patient in a semirecumbent position where he can comfortably and freely expectorate the blood to avoid the retention of clots and aspiration of infected blood. This prevents aspiration pneumonia, atelectasis, and spread of disease. With the free expulsion of the blood, even at the sacrifice of added coughing, the dangers are minimal.

Morphine depresses the cough reflex to a degree where it may cause retention of blood with its harmful sequelae.

Pneumothorax (if one can localize the site of the bleeding and if one has knowledge of the preceding disease—as to its nature and extent) is occasionally resorted to in otherwise uncontrollable hemoptyses. However, the danger of producing atelectasis during active bleeding must be recognized. Collapse of a lung drowned in blood is a questionable procedure at best. When collapse is employed as an

rest in bed in a well-ventilated room or on a porch with adequate but not necessarily excessive feeding. The diet should be well balanced and fortified by an ample supply of vitamins and minerals. Duration of strict bed rest treatment and the pace of its gradual relaxation must be strictly individualized under varying circumstances.

Experience in judging the progression or regression of the disease is a vital requirement for the general practitioner in the management of his patient. In principle, the patient under treatment is kept under constant observation and with management as outlined above. Close study should be made of the course of temperature, pulse, weight, and symptoms, as well as of changes in physical signs and x-ray lesions.

Clinical improvement is often soon achieved, but even complete subsidence of all symptoms does not necessarily mean healing. Under treatment, tuberculous lesions may become and often remain stabilized for long periods without going on to ultimate healing.

The goal of treatment is healing by resolution or by visible fibrosis in x-ray, with persistent negative gastric washings after the patient no longer coughs or expectorates or manifests any symptoms. Depending on the extent and character of the lesion when treatment began, a proportionately long rest period must be carried out and followed up by a control period of graded exercise before a lesion can be considered arrested, even after it appears fibrotic by x-ray and the gastric washings are negative.

In the management of pulmonary tuberculosis the general practitioner's daily routine will consist largely in treating such symptoms as cough, night sweats, anorexia, pain, hemoptysis, and laryngeal and gastrointestinal symptoms. At times, emergencies such as spontaneous pneumothorax or serious hemoptyses will require his immediate attention. He may also have to deal with complications such as diabetes, pregnancy, and extrapulmonary tuberculosis. Not infrequently, his resourcefulness will be taxed to the highest degree in tactfully handling personalities resistant to prolonged confinement to bed.

Last to be mentioned here, but not of least importance, is the responsibility of the general practitioner to institute promptly a campaign of prevention in every family where a case of tuberculosis has turned up. Isolation of the patient is, of course, the first step, with investigative tuberculin and x-ray studies of all contacts. The implications of this are too important to be discussed in the few minutes at

our disposal. All we can do is to emphasize its significance.

Finally, may we express the hope that in the near future practically all cases of pulmonary tuberculosis will be discovered so early by the general practitioner, and that social and economic conditions will improve so markedly, that the great majority of these patients will be treated by him in their homes.

DR. FORKNER: I think I am right in saying that tuberculosis is still the most common cause of death in the young adult. I think that is a point well worth remembering. There are about 20,000 cases of tuberculosis in New York City at the present time. In general, I believe our medical schools often place too little emphasis on tuberculosis. The feeling is as though it were a disease of the past rather than the present.

Now we shall open the subject for general discussion. Are there any questions or does anyone wish to discuss some point Dr. Mayer brought up?

DR. HARRY GOLD: What is so-called early minimal tuberculosis today and what proportion of early minimal cases of pulmonary tuberculosis with positive sputum are likely in the end to turn out to require pneumothorax for cure?

DR. MAYER: Our concept of early pulmonary tuberculosis has recently undergone substantial changes.

In the first place, it must be understood that early tuberculosis is not necessarily minimal and vice versa. Minimal tuberculosis is not necessarily early. A fair proportion of cases of pulmonary tuberculosis is acute from its incipency and begins with an infiltration of a size far from minimal. A still greater proportion of cases of pulmonary tuberculosis is aborted when still minimal in extent and is more often than not discovered only after it has lain dormant for years. The bulk of pulmonary tuberculosis is a chronic progressive disease, which, as you know, hardly ever reaches our hospitals or clinics before it is in a moderately advanced, and much of it only in the far-advanced, stage.

When discovered in practice, minimal tuberculosis is hardly ever early. The definition "early and minimal tuberculosis" is strictly applicable only to the cases picked up in case-finding surveys. The more acute or subacute forms of early tuberculosis are not minimal when discovered even in cases kept under constant surveillance.

Now, as to the question of their treatment by pneumothorax, early subacute forms of

lished by the American Medical Association in 1939.

DR. CATTELL: Do you not recommend ultraviolet light at the present time for pulmonary cases?

DR. MAYER: I personally do not recommend it. I do not think it is indicated.

DR. JANET TRAVELL: How about humidity? Is a dry climate to be preferred to a damp one?

DR. MAYER: In general, I should say that a dry climate is to be preferred to a damp one. I should certainly stress that if you are referring to extreme dampness. On the other hand, if you refer to the climate of the coast of Florida as damp—it is often spoken of in that way—then I have to detail my answer. There are certain cases of tuberculosis with severe harassing cough that are aided by going to such a climate as Florida. The cough is greatly relieved there. If we examine the locations of our municipal sanatoriums, we find them in New York near large bodies of water in comparatively damp sections, and yet the results in the treatment of the patients there are apparently good, despite, if you will, the great humidity. I do not believe we can generalize on the advantages or disadvantages of various climates. We must evaluate the individual case. The preference for a dry climate over a relatively damp climate depends often on the physician's personal experience. The factor of climate stands out much less prominently than the other factors of a resort—namely, the environment favorable for the sick, the resort regimen, and the greater ease of taking prolonged rest cures in such a resort.

STUDENT: In view of the fact that you institute pneumothorax in a progressive lesion, would you require bed rest just the same?

DR. MAYER: I am glad to have this question for it gives me an opportunity to stress again some important considerations.

Pneumothorax and rest must be employed to supplement each other and can never be used to substitute for each other. Each has its own sphere of application. Healing of tuberculosis is ultimately accomplished by the body. Rest is our chief means of promoting the effort of the body to get control over the infection. One mechanical effect of collapse is to interrupt bronchogenic dissemination—i.e., spread and development of fresh lesions at new sites before local healing has been accomplished in the old lesions. The progression of tuberculosis often cannot be stopped without pneumothorax. In most cases where the lesions are sufficiently advanced so as to need

pneumothorax to collapse a cavity or to control a positive sputum, the process will not heal without sufficient rest to begin with. After the lesions have become well stabilized, a mechanically effective collapse may be continued with the patient back at work, since in due time healing will be accomplished in the lung under local rest alone. Few indeed are the cases in which the mechanical effect of pneumothorax alone suffices for the healing process. In contrast, there are many cases in which adequate rest alone cures.

DR. FORKNER: Dr. Mayer, with regard to bed rest in the early case of tuberculosis, would you give us some idea of how long you would want a patient to remain in bed? Would it be two weeks or would it be two months or longer?

DR. MAYER: This question brings up the most acute problem in the treatment of pulmonary tuberculosis. As you may know, the problem is now brought to the fore by the increasing number of cases of true early and minimal lesions revealed by continued x-ray surveys such as are maintained in hospitals for students of medicine and nursing. Many practitioners have taken the cue and make chest films of patients coming in with trivial complaints. Thus, we are now being faced with this problem almost daily. We do not yet know the correct answer. We are groping in the dark trying to work it out from current experience. There are a few guiding facts. The three possible courses of evolution of these early tuberculous lesions are resolution, breakdown, and healing by fibrosis. The more acute the onset, the more likely are lesions to resolve or break down rapidly. The more chronic the evolution, the more likely are the lesions to break down slowly and heal by fibrosis eventually. There is a critical period for both types of lesions—namely, shortly following the onset. In more acute cases this is measured by a few days to a few weeks. Such lesions may either resolve or break down with a rapidity that is frequently amazing. As you may know, some observers have been misled into speaking of a benign exudative form of tuberculosis in such cases. What they have failed to recognize is that the exudative reaction is merely one phase of a series of events. In the majority of cases, after this acute phase has subsided by resolution of the bulk of the infiltration, there are left at the site residual lesions of a chronic type. In chronic tuberculous lesions the critical time may extend for from many months to a year or two. Within that period they may yet break down and

emergency, its management requires consummate skill.

Occasionally, one must resort to phrenic nerve crushing or rarely phrenicectomy when all other measures have failed.

When answering an emergency call for a pulmonary hemorrhage, the practitioner should always bear in mind that his success in reassuring the badly frightened patient by creating an atmosphere of complete confidence as to a favorable outcome and the usual lack of serious significance of the event in the subsequent course of the disease is perhaps the most effective therapeutic achievement.

DR. CARL MUSCHENHEIM: I am going to ask Dr. Mayer whether he will say a few words about the place of tuberculin in pulmonary tuberculosis.

DR. MAYER: Tuberculin therapy still has some exponents. Except in the chronic sluggish productive type, practically all workers have discarded the use of tuberculin therapy for pulmonary tuberculosis. Even in productive tuberculosis, only the rarest use of it is found and with mighty doubtful results.

DR. McKEEN CATTELL: We used to hear a great deal about fresh air, diet, and heliotherapy. How important are these today in the management of tuberculosis?

DR. MAYER: As I stressed in my previous remarks, rest is the most important factor in the treatment of pulmonary tuberculosis. This includes rest of mind as well as of body. Fresh air still plays a real part in treatment. What do we mean by fresh air? Must the patient live as many hours as possible out in the open, living and sleeping on an outdoor porch? Must it be country air or air of a particular climatic resort? Is it satisfactory to take the cure in a bedroom with the windows sufficiently open to recognize the presence of what we call cool moving fresh air?

I should say that everyone would agree that fresh air is an important part of the treatment of pulmonary tuberculosis, whether it is in the city or in the country, in a specific climatic resort such as the desert of Arizona or the dry colder regions of the Adirondacks, or in certain mountainous climates, as Asheville, North Carolina, or Colorado. The indications for such different localities are at present based upon clinical impressions that have developed through experience. It is preferable that the patient, if possible, lie out in the open on a porch and, if the climate is not too severe, that he sleep there at night. For obvious reasons it is also preferable, if the economic status permits it, that a patient take the fresh air cure

in the country. However, today the economic features stand out so prominently in advising treatment that it often sways us in making compromises, so that many patients take their fresh air rest cure in municipal hospitals in city quarters or at home in rooms with the windows open. The results under such circumstances are on the whole apparently satisfactory, even though perhaps not as good as in the case of patients who are sent away. Satisfactory comparable statistics on the end results of treatment in cities compared with that in the country do not exist.

As to diet, formerly patients were regularly put on forced feeding. This has been discarded and, today, it is recognized that the diet indicated is one that should be of sufficient caloric intake to have the patient attain his usual maximal weight of the past, that it should have a so-called adequate supply of vitamins and minerals, that it should usually be enforced with at least a few glasses of milk daily to be certain of the optimum intake of calcium, and that empirically at least the addition of codliver oil is valuable. Vitamin C has recently been particularly advocated, so that the daily intake of at least 50 mg. should be supplied. In more severe and active and extensive cases perhaps 200 to 300 mg. daily should be administered.

As to heliotherapy for uncomplicated pulmonary tuberculosis, no clinical evidence is at hand to prove the indication for the use of light. The lack of accurately controlled observations among certain workers makes it necessary to accept their favorable reports most cautiously. Stationary pleural tuberculosis has been helped by the use of light. Benefits are obtained by patients suffering from tuberculosis of the bones and articulations, peritoneum, intestine, lymph nodes, and the larynx when the entire body is exposed to carefully graded doses of natural sunlight or to radiation emitted by certain artificial sources of light rays.

In tuberculosis of the skin, lupus vulgaris alone responds to light as a rule. Scrofuloderma and erythema induratum react less constantly and lupus erythematosus does not respond or may even be aggravated. Genito-urinary tuberculosis deserves a trial of light therapy in combination with other measures. Postoperative sinuses of tuberculous origin are responsive to light. As to the sources of light, experience has taught us that there are certain indications for artificial sources as against sunlight. These I cannot detail now, but I refer you to the *Handbook of Physical Therapy* pub-

sidered most justifiable in young people in whom tuberculous lesions are notoriously unstable in character. I am speaking of the age group between 15 and 25 and more particularly of the female. I am inclined to believe that some of the lesions in this age group have a more progressive tendency now than was the case in those seen fifteen to twenty years ago.

With this new type of minimal tuberculosis which can progress so rapidly we are compelled to play safe. We have no criteria in deciding which ones of these, although they are free of symptoms, are going to progress rapidly and which ones are not and, when we first find them, we cannot be certain without previous study whether they are healing or not and on that basis we have to play safe.

One should particularly emphasize that neither x-ray nor clinical signs are entirely reliable guides. Apparently, tuberculous lesions can, and often do, progress without symptoms even while the patient is actually gaining weight and seems to improve in every way. It is common to observe that the patient loses all constitutional symptoms just when the lesion has broken down and spread. Until the new crop of lesions has developed so as to become visible by x-ray or become manifest by symptoms, there will be a period of complete freedom from signs and symptoms.

STUDENT: Will you comment on management of pregnancies in relation to pulmonary tuberculosis?

DR. MAYER: We have come a long way from the long and rigidly held point of view which said that a tuberculous woman should not become pregnant, that if she does the pregnancy should be interrupted, and that if she bears a child she should not nurse. It is still true that pregnancies are poorly tolerated by many tuberculous women and that they often prove to be aggravating in active cases and may reactivate unstable lesions. When pregnancies complicate active or unstable lesions, it is still the best policy to terminate them if discovered within the first three months. In the light of recent experience, however, we no longer look upon pregnancy as a serious complication. With proper management of both the tuberculosis and the pregnancy, undue risks may be eliminated in the majority of cases. Pregnant women have been shown to tolerate well the usual procedures for the treatment of their pulmonary lesions. Sometimes surgical delivery may be deemed more advisable if labor appears difficult.

In the present phase of tuberculosis control the practitioner should realize that this disease

must not stand in the way of its women victims' most precious purpose in life—namely, the rearing of a family. Intensive preventive measures against tuberculosis in young married patients are necessary. An x-ray of every young woman who intends to or has already become pregnant is desirable. Planned pregnancies are a part of modern birth control and from the standpoint of tuberculosis they are more than justified—they are an absolute necessity. The tuberculous young woman should be well apprized of the safe and unsafe period for pregnancy according to the exigencies of the individual case. In cases where pneumothorax treatment is employed, the years during which the process is well under control are often the safest period for a tuberculous woman to have her children. The period of activity of the tuberculosis and at least a two-year period following arrest of the process should be considered unsafe for childbearing.

STUDENT: What proportion of the patients who are found with minimal lesions and are adequately treated with rest are subsequently discharged as arrested cases?

DR. MAYER: For the minimal case in general, I should say that 90 per cent of them are cured when competently managed. This means that approximately 10 per cent of these will progress regardless of rest treatment. In truly early minimal tuberculosis some workers feel that they can control practically 100 per cent of them. In hospital and institutional work where they are on the alert for the early minimal case, they know exactly when the lesion is developed and put them to bed immediately. Of the minimal cases found in general practice, I feel that at least 10 per cent would progress regardless of what you do.

STUDENT: But, of these early minimal cases discharged and thought to be perfectly cured, are there not always some who subsequently run into trouble again five or ten years later?

DR. MAYER: We haven't enough data on that point.

DR. SEYMOUR RINZLER: I should like to know the approximate incidence of tuberculosis in diabetes.

DR. MAYER: The incidence is generally considered to be higher in the diabetic than in the nondiabetic patients, but there is still a difference of opinion.

DR. TRAVELL: Would the management of the minimal lesion in a diabetic be any different from that in a nondiabetic patient?

DR. MAYER: It is essential to control the diabetes. With the diabetes controlled, the

spread. One can never be sure of their ultimate fibrosis and healing until that stage has been safely passed. Even after that, the possibility of exacerbation of the lesion still exists for another year or two but becomes less likely with every year passed in safety.

Accordingly, the period of bed rest is determined by the extent and the acuteness of the process at the onset and the course taken in the first few months. An initial period of bed rest of a few months is indicated for practically every case. The more acute the onset or the more extensive the lesion at that time, the longer the period of bed rest that should be planned. The more chronic the onset and the less the extent of the lesion, the more uncertain are we as to its time of origin and, therefore, the period of rest it requires. At best, the proper treatment of such a case is problematic. Here, the age of the patient, the character of the x-ray features, and the clinical and laboratory findings (sedimentation rate, blood picture, history of exposure), etc., should be considered. The younger the patient, the more likely are we dealing with a fresh lesion still within the critical period. The minimum time to be considered should be about three months. In some cases this may have to be extended to six months or even a year. I believe that after an initial period of about three months' rest the majority of these lesions will show the course they are likely to take. Those patients, then, with unchanged chronic lesions often do as well under close observation at home as they do in sanatoriums. These chronic lesions may need close watching for a few years, and it is not reasonable to keep them in institutions for such long periods. The effect of such treatment on the morale of these symptomless patients would be worse than the disease. Observation with frequent x-ray examinations can be made equally well in the home and office.

DR. FORKNER: Not infrequently in these instances, the x-ray report states that the lesion is healed. Would you depend on that?

DR. MAYER: To rely upon the interpretation of a single x-ray film is to invite disaster. I have pointed out before that minimal lesions discovered in practice are mostly not early. Many such lesions may be old and practically healed when they are discovered. Six to ten months is a fair period in which such a minimal lesion may be completely resolved or fibrosed. However, we are hardly ever able to discover how early the lesion is from the features of any single film alone. Certainly we can never be certain about it. To be sure, a series of x-ray

pictures is a great help and, if the films are technically comparable, the shadow showing a tendency of the tissue to shrink, harden, and become stringy is a fairly reliable indication of fibrosis, particularly if increased translucency (emphysema) of the surrounding lung areas is also in evidence. The more chronic the character of an early lesion, the longer is the period of uncertainty as to its ultimate tendency even by observation in serial x-rays.

Let me illustrate this with the case of a school teacher whom I saw quite recently. A lesion was seen that might have been interpreted fibrotic in nature. It had a somewhat nodular appearance and in view of my own sad experience in the past I advised that the patient go to bed. She consulted a few other doctors who told her there was no active lesion. There were no symptoms and six months later I met her physician who was eager to tell me how unnecessarily I had frightened the patient because she was perfectly well and going about her work. Last week, which was three months later, she had a severe breakdown. It was nine months after the appearance of a supposedly fibrotic lesion in the x-ray before it rapidly liquefied. She now has small cavitation.

STUDENT: In view of what you said about bed rest for those patients, why must pneumothorax, if given, be maintained for many years in early cases.

DR. MAYER: As I have already stated, the majority of early cases do not require pneumothorax, particularly if they are still in the minimal stage. The early cases that do require pneumothorax treatment are those that have shown rapid breaking down tendency, early spread, and extension beyond the minimal stage. Here, the extent and character of the lesion at the time of collapse should determine the duration of collapse treatment required. Let me emphasize again that the age of the lesion—i.e., whether early or old—is of no significance from the standpoint of collapse therapy. In fact, too early lesions should not be collapsed until they have revealed their tendency. Early lesions may soon advance to an extent and character as to require the maximal length of collapse. Collapse is often applied to an early small lesion that because of a positive sputum or positive gastric content is suspected of a tendency to softening. In such cases pneumothorax should not be maintained for more than a period of one or two years.

Perhaps it should be pointed out that the collapse therapy in early lesions is now con-

MEDICAL PREPAREDNESS

Registration of Men Between
the Ages of 45 and 64
on April 27, 1942

WHEN the Presidential proclamation was issued setting Monday, April 27, 1942, as the date for registration of all men between ages 45 and 64, Selective Service in New York City arranged for a Special Local Draft Board to sit in the Waldorf-Astoria Hotel on that date. In this way, provision was made so that members of the House of Delegates from *outside of New York City* would meet no interference with attendance at the meeting.

On April 2, 1942, a proclamation was issued by Governor Lehman opening registration by the Local Boards throughout New York State on the *two preceding days*, as follows:

Saturday, April 25, 1942—1:00 P.M. to 6:00 P.M.
Sunday, April 26, 1942—1:00 P.M. to 6:00 P.M.
Monday, April 27, 1942—7:00 A.M. to 9:00 P.M.

On this schedule it will be possible for all members concerned to register before leaving for New York City. However, they will still be able to register with the Board in the Waldorf-Astoria since Selective Service will maintain that arrangement notwithstanding the general change in schedule shown above.

Members living in New York City boroughs, who are not eligible to register with the Waldorf Board, will find it easier to visit their own local boards on Saturday, April 25 or Sunday, April 26, thus avoiding possible delay in reaching the Monday meeting.

LOUIS H. BAUER, M.D., *Speaker*
PETER IRVING, M.D., *Secretary*

management and outlook for the tuberculosis is pretty much the same as without the diabetics.

In summing up, let us briefly recapitulate:

1. In every case of chronic pulmonary tuberculosis, there is a time when the lesion is so early and minimal that treatment is but a matter of a few months of bed rest under the care of the general practitioner.

2. There is a critical period for all tuberculous lesions shortly following onset. In more acute cases this period is measured by

days or weeks, in more chronic lesions it extends over months. The decision for or against collapse must be reached on the basis of experience in judging events of this period.

3. Early diagnosis that will bring the patient under treatment when bed rest will still arrest the lesion will cut the process short in all but a few of the cases.

4. Initiation of collapse treatment at the optimum time on the basis of ripe judgment as to the trend of the process will effect cure in the majority of the cases.

THE THERAPEUTIC VALUE OF PUPPETS

The educational value of puppetry is less well known than its entertainment and commercial values, says an article by Jeanetta Lyle and Sophie B. Holly, R.N., in the *Bulletin of the Menninger Clinic*. Puppets have long been used in schools, however, where they lend themselves ideally to the teaching of such subjects as geography, history, home decoration, dress design, stagecraft, and dramatics. Their therapeutic possibilities in a program of re-education of the mentally ill have been recognized comparatively recently. Child therapy has utilized them most effectively in attempts to learn more about the nature of the child's conflicts which, with his limited vocabulary, he is unable to express adequately in words but can express in play with dolls and toys. A number of reports of this type of work with maladjusted children under the guidance of child analysts have been published.

The reaction of adult patients who may also be unable to express their conflicts verbally because of regression and strong inhibitions to puppet making and use has been less adequately studied, although some observations have been made. This method of recreation in a hospital is prescribed as is any other activity, mental or physical, for the purpose of contributing to lasting recovery from disease. It serves the therapist as a means of investigating the patient's difficulties and of helping him to solve them, and it helps the patient to dramatize his fantasies in a creative way. It leads almost inevitably to some kind of social relationship, because wherever there is a dramatic representation there must be an audience, even if it is only one person.

One of the best things about puppetry as a therapy is that it is so versatile. A puppet may play many roles, not only on the stage, but in the treatment of patients. For one person, the building of a being who walks and talks may satisfy a deep creative urge; for another, the complete control that he gains of the puppet's mechanism may expand his ego by giving him a sense of mastery; for another, the antics of the

puppet may express the exhibitionistic strivings that he cannot give vent to himself; and for another, the puppet may become an agent through which he can express inhibited aggressiveness

Sometimes a patient identifies himself with his puppet and cannot be parted from it, taking it to his room and even taking it home with him when he leaves the hospital. The puppet to him takes on a personality, just as Charlie McCarthy has developed an individuality for the radio public that is more real than that of many human performers. One young schizophrenic boy modeled a puppet that looked a little like himself. This puppet first played the part of Jack in *Jack, the Giant Killer*, and later appeared as Gluck in *The King of the Golden River*. Because of his ingenious expression and the hero parts which he played, he soon became the favorite of all the patients and his "master" enjoyed the reflected glory. He enjoyed playing with "Gluck," had him outfitted with a new suit in the women's occupational therapy department, and took the puppet home with him when he recovered sufficiently to leave the hospital, much to the regret of some of the other patients who had also grown fond of the little mannequin. It was quite evident in this case that the success of the puppet brought to this youth the renewed hope and interest in life that a human friend sometimes gives.

One rather touching example of this close identification with a puppet was shown in a presentation of Robinson Crusoe. A depressed schizophrenic man who was manipulating the puppet who took the part of Friday came to the lines where Friday begs Crusoe not to leave him behind on the island. Standing on the bridge over the miniature stage, the patient forgot all about pulling the strings of the puppet and turning to the therapist with tears streaming down his cheeks, he recited the passionate plea not to be left alone directly to the therapist.

{Continued from page 822}

Candidates for re-examination in Part II must make written application to the Secretary's Office before April 15, 1942.

As previously announced in the board booklet, this fiscal year (1941-1942) of the board marks the end of the two-group classification of applicants for examination. Thereafter, the board will have only one classification of candidates, and all will be required to take the Part I and Part II examinations.

The board requests that all prospective candidates who plan to submit applications in the near future request and use the new application form which has this year been inaugurated by the board. The Secretary will be glad to furnish these forms upon request, together with information regarding board requirements. Address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

Defense Savings Bonds

From the Defense Savings Committee for the State of New York, which operates under the National Defense Savings Staff, at 1270 Sixth Avenue, New York City, has come a request to publish the following information about the Defense Savings Bonds now on sale.—Editors

DEFENSE SAVINGS BONDS come in three issues, called E, F, and G. They are all registered bonds and are not transferable, which means that they cannot be sold and cannot be used as collateral for a loan, but they will be redeemed by the government before their maturity, at the request of the owner. They can be registered in the name of one individual, or in the names of two individuals as co-owners, or in the name of one individual as owner and another individual as beneficiary. They will be held for safekeeping without charge by any Federal Reserve Bank, if desired. They are all taxable, but only by the Federal Government, as to income, gift, or inheritance taxes.

The differences in the issues are as follows:

Series E. This is an appreciation bond. It pays no interest, but it is sold to the investor at a discount: \$18.75 for a \$25 bond, \$75 for a \$100 bond, etc., and if held for the full term the increase in value will be equivalent to 2.90 per cent compound interest.

It comes in denominations of \$25, \$50, \$100, \$500, and \$1,000 (maturity value).

Its maturity is 10 years from the date of issue.

The cost is three-quarters of its maturity value.

Only \$5,000 (maturity value) may be purchased by an individual in any one calendar year.

It will be redeemed by the government at any time after 60 days from the time of purchase, without capital loss but with diminution in the rate of increase in value.

Series F. This is also an appreciation bond, and if held for the full term the increase in value will be equivalent to 2.53 per cent compound interest.

It comes in denominations of \$100 up to \$10,000 (maturity value).

Its maturity is 12 years from the date of issue.

The cost is a little less than three-quarters of its maturity value.

Only \$50,000 (cost value) may be purchased by an individual in any one calendar year.

It will be redeemed by the government at any time after six months from the time of purchase, but only on the first day of the month and one month's notice is necessary.

It is redeemed without capital loss, but with diminution in the rate of increase in value.

Series G. This is a current income bond, paying 2.50 per cent a year; payments semi-annual.

It comes in denominations of \$100 up to \$10,000 (cost and maturity value the same).

Only \$50,000 may be purchased by an individual in any one calendar year. This same limitation applies to a combination of F and G bonds, a \$50,000 limit on F and G bonds together purchased in one calendar year.

It will be redeemed by the government at any time after six months from the time of purchase, but only on the first day of the month and one month's notice is necessary. It is redeemed at a discount.

Arrangements can easily be made with any Federal Reserve Bank or any Savings Bank for the purchase of these bonds. Checks may be sent to them regularly and the bank will buy the bonds and either send them to the purchaser or hold them in safekeeping. The checks need not be for the exact amount to purchase a bond. The bank will buy one when the amount in hand is sufficient and will hold over the surplus toward the purchase of the next bond.

In a bank (Savings Bank or otherwise) where you have a deposit, you may authorize the bank, until further notice, to charge your account so much per week and to buy the bonds as the amount becomes sufficient, while you make deposits at such intervals as may be convenient. In Savings Banks these deposits should be at least as much, in the course of a year, as the cost of the bonds purchased, so as not to deplete your savings account.

These bonds can be purchased at your local bank, at any Federal Reserve Bank, or at Savings Banks. Checks may be sent to them regularly and they will buy the bonds, and they will either send them to the purchaser or will hold them in safekeeping. In many Savings Banks there are arrangements by which an individual may deposit smaller amounts regularly, and they will buy a bond as soon as the amount becomes sufficient, holding over any surplus money as a start toward the purchase of the next bond.

EXAMINATIONS—AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

General oral and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted at Atlantic City, New Jersey, by the entire board, from Thursday, June 4, through Tuesday, June 9, 1942, prior to the opening of the annual meeting of the American Medical Association.

Group A, Part II, candidates will be scheduled for examination in the first part of the examination period, and Group B, Part II, in the latter half. Formal notice of the time and place of these examinations will be sent each candidate several weeks in advance of the examination dates.

Woman's Auxiliary

To the Medical Society of the State of New York

IT'S spring again—and with spring comes your 1942 convention of the Medical Society of the State of New York. Tuning in for a bit of last-minute news, this is what I heard—a voice singing: "I like New York in April—what about you?"

"Mary, that song goes 'New York in June.'"

"Not this year, George. It's April—the convention. And don't forget, we have a date to take that spring vacation you promised."

"Right you are, Mary. Have you made reservations?"

"Yes, indeed, and the Waldorf sent me word today that from the doorman down to the last bellboy they are ready for the convention and our visit. So I'll pack our grip and we'll take that trip to New York Town."

How about you, sister members—did you extend that invitation I told you about to all doctors' wives? Tell them about the House of Delegates meeting on Monday afternoon and Tuesday morning, the auxiliary banquet on Monday night in the Starlight Roof, the dinner of the Medical Society on Tuesday night in the Grand Ballroom, the tea on Tuesday afternoon at Louis Sherry's, and the luncheon on Wednesday at Theresia Worthington Grant's.

Have you saved that penny and saved that dime, so I'll be seeing you at convention time?

Mrs. H. F. Pohlmann,
Convention Chairman

Another reminder: make your reservations for the Annual A.M.A. Convention, June 8-12. Send your request at once to Haddon Hall, Atlantic City, New Jersey.

County News

Columbia. A luncheon meeting was held on March 31 at the General Worth Hotel, Hudson. Mrs. Alfred Madden, state legislative chairman, was the guest speaker. This was an open meeting.

Fulton. Members of the auxiliary held their annual meeting and election on March 10 at the home of Mrs. J. Frederick Sarno. Officers elected are: president, Mrs. John A. Shannon; president-elect, Mrs. Louis Tremante; first vice-president, Mrs. John H. Larrabee; second vice-president, Mrs. J. J. Thompson; treasurer, Mrs. L. H. Backus; recording secretary, Mrs. Francis S. Hyland; corresponding secretary, Mrs. J. F. Sarno; historian, Mrs. Woodard Shaw; director, Mrs. J. Edward Grant; hospitality, Mrs. Robert Lenz; parliamentarian, Mrs. Arthur R. Wilsey; membership, Mrs. William J. Kennedy; publicity and press, Mrs. Austin Hogan; *Hygeia* and Red Cross, Mrs. H. B. Riggs; program, Mrs. B. G. McKillip; legislation, Mrs. R. T. Furlong; finance, Mrs. William F. Heseck; *Bulletin*, Mrs. A. J. D'Errico; public health and public relations, Mrs. Kenneth Foster. Following the business session, a social time was enjoyed and refreshments were served.

Jefferson. A silver tea for the benefit of the shut-in children at the Bide-A-Wee Hospital was held at the home of Mrs. Emmett B. Dunlay. The women who poured were Mesdames Robert G. Horr, Charles A. Phelps, Louis W. Moore, Charles T. Learned, Harold W. Conde, Henry H. Babcock, Percy H. Willmott, Valo A. Bradbury, and Maurice D. Barnette. On January 17 the Woman's Auxiliary participated in the sale of defense stamps under the direction of Mrs. Sutherland E. Simpson. Later in January, under the chairmanship of Mrs. Walter Fox Smith, more defense stamps were sold. Mrs. Wendell D. George, Mrs. G. Harry Righter, and Mrs. Emmett B. Dunlay also assisted. A regular dinner was held March 12 at the Black River Valley Club. The auxiliary held its meeting prior to the medical society meeting. Dr. F. R. Calkins addressed the auxiliary on "Cancer Control." The meeting then adjourned to give the women an opportunity to hear the address by Dr. George S. Nellis, a lieutenant-commander in the United States Naval Reserve, on "Civilian Defense Against Chemical Warfare."

Madison. A covered-dish supper was held at the home of Mrs. Otto Pfaff. Mrs. Lee S. Preston, president, introduced the guests of honor, Mrs. George B. Adams, state president, and Mrs. George C. Sincerbeaux, state corresponding secretary, both of Auburn. The members of the Doctors' Club of Oneida joined the ladies to honor Dr. and Mrs. Charles Earl. Dr. Earl recently left to join the United States Navy. Mrs. Earl is a past-president of the auxiliary.

Nassau. On April 28 at 2:00 p.m., a trip was made to Meadowbrook Hospital. The speaker was Dr. A. J. McRae.

Orange. The executive board of the Woman's Auxiliary met Tuesday, March 17, at the home of Mrs. J. Emerson Noll in Port Jervis. The members attending the luncheon and the business meeting which followed were: Mesdames W. W. Davis, N. T. Keyes, L. T. Seward, C. E. Fallon, J. W. McKeever, C. S. McWilliam, P. H. Faivre, H. F. Pohlmann, J. W. Walton, H. F. Murray, J. E. Noll, and G. E. Kenny. The president, Mrs. W. W. Davis, conducted the business session. Plans for the general meeting held in Middletown, April 2, and the annual convention to be held in New York, April 27-30, were discussed.

Schenectady. The public was invited to the Medical Auxiliary Nutrition Institute, March 25 and 26. Mrs. A. Grussner was chairman of the event. Exhibits illustrating the principles and practice of nutrition filled the solarium both days. These exhibits included movies, skits, panel discussions, and lectures.

We congratulate, and welcome to our midst, Livingston County, whose president is Mrs. Kenneth T. Rowe.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

Sulfonamide Therapy

A course of three two-hour sessions, arranged by the Council Committee on Public Health and Education, Medical Society of the State of New York, and the New York State Department of Health, for the Orange County Medical Society, is to be held at the Horton Memorial Hospital, Middletown, at 8:00 P.M.

FIRST SESSION, Tuesday, May 12—Behavior of Sulfonamides in the Body and Principles for Their Use.

Alexander D. Langmuir, M.D., deputy commissioner, Westchester County Department of Health, Peekskill.

Local and Internal Use of Sulfonamides in Surgery.

Frank Glenn, M.D., assistant professor of clinical surgery, Cornell University Medical College, New York City.

SECOND SESSION, Tuesday, May 19—Treatment of Genitourinary Infections in the Male.

Thomas F. Laurie, M.D., associate professor of urology, Syracuse University, College of Medicine, Syracuse, New York.

Sulfonamides in Obstetrics and Gynecology.

R. Gordon Douglas, M.D., associate professor of obstetrics and gynecology, Cornell University Medical College, New York City.

THIRD SESSION, Tuesday, May 26—Treatment of Pneumonia.

L. Whittington Gorham, M.D., professor of medicine, Albany Medical College, Albany, New York.

Treatment of Meningitis.

Harry Bakwin, M.D., associate professor of pediatrics, New York University Medical College, New York City.

This instruction is a cooperative endeavor of the New York State Department of Health and the Medical Society of the State of New York.

Maternal Welfare Teaching Day at Albany

A regional Maternal Welfare Teaching Day is being held Wednesday, April 15, at the Albany Hospital, Albany, under the auspices of the following organizations: the maternal welfare committees of Albany, Columbia, Rensselaer, Saratoga, Warren, and Washington counties; the Albany Medical School; the Northeastern New York Obstetrical and Gynecological Society; the Division of Maternity, Infancy, and Child Hygiene of the New York State Department of Health; and the New York State Medical Society.

The meeting will convene at 12:00 noon, with Dr. Joseph O'C. Kiernan, regional chairman in obstetrics, Maternal and Child Welfare Committee of the New York State Medical Society, presiding, and Dr. R. S. Cunningham, dean, Albany Medical College, introducing the scientific addresses.

The first of these will be a paper on "Chemotherapy in Obstetrics," by Dr. Ferdinand J. Schoeneck, associate professor of clinical obstetrics, Syracuse University College of Medicine. The session after luncheon, which will be served at the hospital at 1:00 P.M., will be given over to addresses by Dr. Edward C. Hughes, professor of clinical obstetrics, Syracuse University College of Medicine, on "Toxemias of Pregnancy"; Dr. Vincent P. Mazzola, instructor in obstetrics and gynecology, Long Island College of Medicine, Brooklyn, on "Complications of Pregnancy: Heart Disease, Tuberculosis, and Diabetes"; and Dr. Schoeneck, on "Proposed Consultation Service in Obstetrics."

The program committee consists of Drs. John G. Hayes, Kenneth M. Archbold, Joseph W. Cooney, Jacob L. Lochner, Jr., and Mary D. Pettit. The committee on arrangements includes Drs. Thomas O. Gamble, William J. Fitz-Gerald, G. Emery Lochner, Alfred L. Madden, and Paul Schultze, Jr.

PHYSICIAN IN "NEW-YORK"

The hyphenation of New York is the publisher's in a book printed in 1806 and written by Shadrach Ricketson, "physician in New-York." The following abstract, taken from a copy purchased by Dr. David Hosack, who was an intimate friend of George Washington and Benjamin Franklin, appears at the front of the book and is apparently a form of copyright.

The material reads:

District of New-York, etc.

(L.S.) Be it remembered, That on the twenty-ninth day of August, in the thirty-first year of the Independence of the United States of America, Shadrach Ricketson, of the said District, hath deposited in this Office the title of a book, the right whereof he claims as Author in the words following, to wit:

"Means of preserving Health and preventing Diseases; Founded principally on an attention to Air and Climate, Drink, Food, Sleep, Exercise, Clothing, Passions of the Mind, and Retentions and Excretions, With an appendix, containing Observations on Bathing, Cleanliness, Ventilation and Medical Electricity; and on the Abuse of Medi-

cine. Enriched with apposite extracts from the best Authors. Designed not merely for Physicians, but for the information of others. To which is annexed a Glossary of the Technical Terms contained in the Work—By Shadrach Ricketson, Physician in New-York."

In conformity to the Act of the Congress of the United States, entitled "An Act for the Encouragement of Learning, by securing the copies of Maps, Charts and Books to the Authors and Proprietors of such copies during the times therein mentioned;" and also to an Act entitled "An Act supplementary to an Act entitled 'An Act for the Encouragement of Learning by securing the copies of Maps, Charts and Books to the Authors and Proprietors of such copies during the times therein mentioned,' and extending the benefits thereof to the arts of designing, Engraving and Etching historical and other prints."

Edward Dunsecomb

Clerk of the District of New-York

Today we just print "Copyright 1942" and leave the rest to the imagination.

 Riverdale-on-Hudson, New York City
 For nervous, mental, drug and alcoholic patients. The sanitarium is
 beautifully located in a private park of ten acres. Attractive cottages,
 scientifically air-conditioned. Modern facilities for shock treatment
 Occupational therapy and recreational activities. Doctors may direct
 the treatment. Rates and illustrated booklet gladly sent on request.

"SHOCK TREATMENT" IN GREAT-GRANDFATHER'S DAY

Long before the first electric light, electric machine,
 and the modern diathermy apparatus, doctors were quite
 interested in electricity medically. In fact as early as
 1806 a medical author devoted an entire chapter to
 "Medical Electricity"—a chapter that consumed an entire
 page.

This is what he had to say—"Electricity being one of
 the most powerful stimulants, its effect may be consid-
 ered both as general and local. It promotes a free circula-
 tion of the blood, and increases animal heat and perspi-
 ration, as well as all the secretions and excretions of the
 body. It has been frequently used, of late, both as a pre-
 ventive and cure of many diseases. Without enumerat-

ing them all, it will be sufficient to say, that it has been
 found most successful in the following: rheumatism,
 gout, kings-evil, palsy, St. Anthony's fire, St. Vitus's
 dance, epilepsy or falling sickness, gutta serena, nervous
 head-ach, tooth-ach, suppression of the menses, contrac-
 tions and cramps of the limbs, and in various obstruc-
 tions, tumours and ulcers.

"And it has, also, been found one of the most effectual
 means of resuscitating persons apparently dead from
 drowning, suffocation, and other like causes."

Evidently the author ran out of cases in which elec-
 tricity might be indicated, but he could not have missed
 many known to doctors in that era.

RIVERLAWN SANITARIUM

FOUNDED 1893

A conveniently situated Sanitarium offering complete facilities for
 the treatment and care of MENTAL AND NERVOUS CASES
 and ALCOHOL AND DRUG ADDICTIONS. We extend full
 cooperation to the Physicians.

REVIEWED

Encephalitis—A Clinical Study. By Josephine B. Neal, M.D. Octavo of 563 pages. New York, Grune & Stratton, Inc., 1942. Cloth, \$6.75.

The coincidence of the publication of Dr. Neal's latest book, *A Clinical Study of Encephalitis*, at the very onset of World War II is interesting, since encephalitis was one of our heritages from the first World War. The sequelae of that epidemic of encephalitis are still with us, presenting a problem to medical men in general, neurologists in particular, and to draft board and army physicians. Dr. Neal, with her fourteen years' experience on the Matheson Commission preceded by her association since 1910 with the Bureaus for the Study of Infectious Diseases of the Central Nervous System, has a unique position as an authority second to none in the United States on encephalitis. The completeness of this study from every point of view is characteristic of her attitude toward the problem she has undertaken to face. Her observations and conclusions are objective and scientific. The book in itself is not only extraordinarily interesting reading but is a source book that will be valuable to students, general practitioners and, most of all, to neurologists, from whom post-encephalitic patients seek relief from their tragic disease.

KATE CONSTABLE

Surgery of the Heart. By E. S. J. King, M.D. Octavo of 728 pages, illustrated. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$13.50.

In 1896 Rehn recorded the first successful operation upon a living heart—the suture of a wound—although as early as 1650 Riolanus had suggested the possibility of tapping the distended pericardium. Surgery of the heart has progressed rapidly since the beginning of this century with increasing tempo in the most recent years. As Dr. White says in his introduction: "The surgeon who would attempt the treatment

of diseases of the heart must have the courage and optimism of the explorer and be equipped to justify their exploitation."

Although this book consists of over 700 pages and although surgery of the heart has progressed in our day far beyond even the dreams of all previous time, the really practical results are still quite limited. It is, therefore, to the physician, as well as to the surgeon, that the author speaks. It will be possible for cardiac surgery to advance only as the physician learns the possibilities of surgery. The lamp is but just lighted—it needs oil. The cardiologist almost always sees the heart patient first. If he knows what the surgeon has accomplished in solving some of these difficult heart problems, he may aid by his encouragement and knowledge in extending this field.

The first section of the book is devoted to the anatomy, physiology and pathology, and special examinations of the heart, emphasizing the most recent advances found in a wide study of the literature. The main body of the volume considers the surgery not only of the heart itself but also of the pericardium, coronary, and great vessels. The frequent repetitions of the text and bibliography are not accidental. It is the aim to make each subject complete in order that these sections may be used for rapid reference. This makes the work a little more difficult to read in continuity from cover to cover, until the reader becomes accustomed to sensing and skipping the repeated parts.

The author is to be congratulated upon the way he has kept such a voluminous and authoritative book up to date.

NUMBER 9

Editorial

War Shortage of Drugs and Medical Appliances

The subcommittee of the Committee on Public Health Relations of The New York Academy of Medicine has done a noteworthy piece of work in surveying, with the help of representatives of leading drug manufacturers and distributors and from several divisions of the government, forthcoming shortages in essential medical materials. The medical profession has read of the shortages in the essential materials for industry, the priorities which have now been established in many lines, but it has more or less assumed that in some way the basic materials used in the practice of medicine would continue to be available.

However, the supply of drugs from many foreign countries has been drastically curtailed or completely shut off. Lack of shipping facilities has made belladonna and colchicum practically unavailable. Drug substances used in the manufacture of war equipment—alcohol, phenol, glycerine, magnesium, mercury and zinc—are becoming less and less obtainable.

The Army and Navy are taking for immediate use, and storing up against possible future needs, vast supplies of quinine, morphine, sulfa drugs, bandages, surgical instruments, and the like. Lend-Lease requirements are also taking a heavy toll. Materials in this category are being sent to Britain, Australia, India, South Africa, China, Free France, Soviet Republics, and Central and South Ameri-

can Republics. There are priority rulings on materials used in packaging—tin plate and lead, and it is probable that the use of paper cartons and wooden packing cases will shortly be curtailed.

Transportation is developing acute shortages and deliveries are being accomplished under greater and greater difficulties. The U. S. Pharmacopoeia has relaxed storage requirements for some drugs such as ergot and made official substitutes for codliver oil.

The report of The New York Academy of Medicine urges that hospitals and surgeons exercise the utmost economy in the employment of operating-room and other materials and apparatus; that in prescription work tablets and capsules be substituted for elixirs, tinctures, fluid extracts, and preparations containing syrups and glycerine. It is also recommended that every step, including subsidy, be taken to favor the production in this country of certain vegetable drugs hitherto imported. The Academy very sensibly urges that steps be taken to produce in this country previously imported or manufactured items and that official drugs and their preparations together with certain newer chemical drugs be given priority over unofficial and proprietary preparations. In the Medical Preparedness section of this issue may be found the complete report, on page 916, adopted by The New York Academy of Medicine on March 9, 1942.

[Continued from page 828]

new illustrations and references; otherwise it is much the same as the first edition.

The author has produced a small volume on diseases of the nails which is worthy of his great effort in observation, preparation, and production. Here one will find descriptions of all the common and unusual pathologic conditions that affect this cutaneous appendage.

Its division into "Affections Peculiar to Nails," "Unequal Manifestations of Systemic Diseases," and "Congenital Affections of the Nails" gives one an insight into the scope of the work. Since many of the changes in the nails are not characteristic of a specific disease and others are fairly characteristic, the complete elucidation under each heading is helpful.

Finally, there is a list of the occupations in which diseases of the nails are common and a shorter list giving the unequal symptoms due to poisons such as arsenic, aniline, acetanilid, etc.

The book is well written and well illustrated and is produced in a fashion to merit consideration.

E. ALMORE GAUVAIN

Occupational Diseases. Diagnosis, Medico-legal Aspects and Treatment. By Rutherford T. Johnstone, M.D. Octavo of 558 pages, illustrated. Philadelphia, W. B. Saunders Company, 1941. Cloth, \$7.50.

An excellent book has been added to the increasing number of publications on occupational diseases. The author has divided his book into eight parts, each of which deals with a specific group of occupational diseases. The symptomatology of the individual occupational disease is discussed, and then the medicolegal aspects are presented, fortified with suitable case reports.

Much of the recent literature has been included. The chapter on treatment of lead poisoning has been brought up to date to include some discussion on the controversy that exists concerning calcium and phosphorus therapy. Both sides of the controversy are presented. The dust diseases, including the discussion of the relationship of silicosis to tuberculosis, is well presented.

There are many excellent illustrations and x-ray reproductions. The films demonstrating the various stages of silicosis are excellent. The chapter on the "industrial back" is well discussed and the illustrations are adequate. The occupational dermatoses are well illustrated and the discussions of the various types of dermatitis are short.

The book is well recommended because it embraces, in its 558 pages, a brief discussion of the most important occupational diseases and gives the interested reader an adequate bibliography should more detailed information be desired.

With the increasing interest in industrial medicine, this book has a definite place in the growing library on occupational diseases.

IRVING GREENFIELD

Blood Disorders in Children. By I. Newton Kugelmass, M.D. Octavo of 897 pages, illustrated. New York, Oxford University Press, 1941. Cloth, \$10.

This work consists of six sections and an appendix. The subject matter covers with encyclo-

pedic detail the diseases of the erythron, leukon, thrombon, and reticulo-endothelium system. The last chapter deals with the blood pictures in miscellaneous diseases not strictly hematologic.

Whether for pediatrician or adult practitioner this book offers a "multitude" of hematology. At times this appears overwhelming. One misses the congeniality of the author that is so frequent in textbooks on medicine. In physics or chemistry, perhaps congeniality may have no place, but in a book on human beings one welcomes it.

The part on symptom diagnosis is confusing and adds little to offset the already overburdensome encyclopedic trend. Outstanding is the historical comment on the pioneers of hematology.

MAURICE MORRISON

Gynecology and Female Endocrinology. By Emil Novak, M.D. Octavo of 605 pages, illustrated. Boston, Little, Brown & Company, 1941. Cloth \$10.

Dr. Novak has produced a well-planned, excellently organized, and comprehensive text covering the field of diagnostic gynecology and female endocrinology. A minimum space is devoted to topics with which the author feels the reader should be familiar. Though the chapters on anatomy, history-taking, and gynecologic examinations have been reduced to essentials, these subjects have been thoroughly reviewed.

The text is devoted chiefly to diagnosis and therapy. An outstanding feature is that the author does not attempt to discuss operative technique or the discussion of surgical

operation. Such an organization permits the author to summarize in a volume of less than 600 pages the newer contributions that endocrinology has provided in the study of gynecologic physiology and disease.

The author has correlated the anatomic pathology with the altered physiology of gynecologic processes which so often exists as the basis for the disturbed function. As an instance, one can refer to his discussion of ovarian tumors.

The practical considerations of treatment in the endocrinopathies are concise yet complete. With the state of developmental flux of endocrinology at the present time the great value of such a review is that it can well serve as a starting point for future consideration of any given problem in which the reader may be interested.

The author is gifted with an understanding of the contributions from other branches of medicine to gynecology. Specifically, one can recommend his discussion of such diverse topics as "Backaches in Women" and "Problems of Sex-Life."

The wealth of illustrated material, photographs, photomicrographs, including colored plates and diagrams, is outstanding and adds lucidity to the text. Moreover, the inclusion of selected references at the end of each chapter enhances the value of the text as a reference source.

Gynecology and Female Endocrinology by Dr. Emil Novak can be recommended as a text for the student, as a ready reference book for the general practitioner, and as a review of the late developments for the specialist.

MORRIS GLASS

The Cold in Industry

In our all-out efforts to produce the material needed to equip our forces and those of our allies, medicine has an enormous responsibility. We must keep the men and women fit to carry on their work. Probably the greatest cause of industrial incapacity is the common cold, and as yet nothing has been found to prevent it in the manner in which some other epidemic diseases are preventable. Anything in the line of treatment that holds forth promise must therefore be given trial.

Townsend¹ successfully treated a certain type of acute recurrent rhinitis with staphylococcus toxoid and these patients had no return of the infection for at least one year. This type gave the history of frequent afebrile colds, and more or less constant pain in the neck and shoulders. On testing with the allergens, negative skin reactions were obtained. Culture from the nasal mucous membrane yielded

¹ Townsend, K. E.: *Ann. Otol., Rhin. & Laryng.* 50: 1189 (1941).

Staphylococcus albus in almost pure culture. It is recommended that this be taken during the active phase of the disease.

Before treatment with the toxoid is started, sensitivity to its use should be determined by a skin test, using 100 units per cubic centimeter. Treatment is effected by the subcutaneous injection of 1,000 units of toxoid per cubic centimeter, the dosage being increased over an eight-week period from 0.03 to 0.12 cc., depending upon the severity of the skin reaction of the previous week. Where this reaction exceeds 5 cm. in diameter, the therapeutic dose should not be increased.

This low-dose method of treating this type of acute and chronic respiratory infections should be given extensive trial by industrial physicians. Should it succeed in achieving the results Townsend claims for it, it will reduce substantially the number of work hours lost by sickness, hours that are of such vast import at present.

Priorities Might Help

It is always a pleasure to read an article which is filled with the sound medical horse sense of the passing generation of real clinicians. Such an article is that by Smith¹ in our own *JOURNAL* of December 15 last. Flying in the face of the much vaunted "glamour" of our dear ladies, he sings the praises of breast feeding! He points out that breast-fed babies have fewer digestive upsets, and are less susceptible to infections of the upper respiratory tract. The gain in weight of the infant is surer and steadier in the early months and the chances for survival are greater.

There are many factors which have contributed to the almost complete disappearance of breast feeding among women in the middle and upper economic brackets. Their social obligations, the tendency to assign the care of the infant to a nurse, and the pandering of the physician to the natural vanity of the mother instead of explaining the advantages of breast feeding—all these are but a few.

¹ Smith, C. H.: *N. Y. State J. Med.* 41: 2395 (1941)

Then again, with the increase in health education for the laity, the fear of the deficiency diseases and the overemphasis on the various vitamins has led many a mother and her medical adviser to view breast milk as lacking in adequate supply of these substances. As Smith shows, from his long experience at the Bellevue Hospital in New York City, ascorbic acid is present in sufficient quantity in breast milk when the mother eats citrus fruits regularly. And a sufficient quantity of sunlight on the baby's skin is equal to codliver oil in its efficacy.

Of course, the mother must be instructed as to how properly to feed her child at the breast. Nursing too long predisposes to cracked nipples and may make the mother irritable. During the period of weaning, proper guidance is necessary. But all in all, the old saw that, "mother's milk is best for the baby and cow's milk is best for the calf," holds true, and priorities may yet help us to remember it.

This JOURNAL urges upon the Society a most careful reading of the full report and recommendations. It is to be hoped that every physician remaining in civilian

practice will give his earnest and serious attention to this urgent and vital matter. The Academy is to be congratulated upon a splendid research in the public interest.

The Doctors' Dilemma

Much of the attention of medical men is now centered upon the third enrollment of men under the Selective Service Act. The age group, 20-45, is that which affects most seriously the medical students and the younger practicing physicians. Fortunately, the armed forces appear determined that the quality of medical services shall not deteriorate. In consequence, it now seems certain that the continuity of medical education and discipline will not be interrupted but that students in good standing in all acceptable medical schools will be taken into the Medical Administrative Corps.

The younger graduates in medicine, those in reputable practice under the age of 36, will now be principally affected. Speaking at the National Conference on Medical Service in Chicago, on February 15, 1942, Major Sam F. Seeley, executive officer of the Procurement and Assignment Service, said that as of that date about 25,000 enrollment cards had come in to the Service. There are about 65,000 physicians in the country under the age of 45. No man presumably will be assigned to duty by the Surgeon General unless first cleared by the Procurement and Assignment Service. It may be well to stress here that the P. and A. Service has no authority to assign anybody, at any time, or to any place. Medicine, through the P. and A. Service, is the only group in the United States permitted to render its service wholly under the direction of physicians. All business and industry on the contrary is now under government control of some sort.

If the present arrangement for procurement is not disturbed, these physicians entering the armed services will be more nearly fitted into the places for which they are qualified by education and practice than any other group.

The outlook for the men who are not

called to serve with the armed forces is not so clear. The organization of civilian defense still leaves much to be desired. The experience of other countries in this war as pointed out by Dr. Herman N. Bundeson, president of the Board of Health of Chicago, is that about 50 per cent of enemy activities are directed toward the civilian population. If that is to be our experience also, one could wish that a little more realism, more adequate funds, and some authority could be spared by the government for this kind of civilian protection and especially for the emergency medical service, which, for all its willingness to serve, is ill equipped, confused as to organization, and only in a few places sufficiently drilled and integrated with civil protection units.

It is difficult to understand how the P. and A. Service can operate to assign physicians not physically fit for military service or over age to function with a civilian defense organization, which does not seem to know just what it is, where it is going, or what it will do when it gets there. And yet this is the problem confronting those physicians who will not be called for duty with the armed forces but are yet charged with the proper medical care of the civilian population, which is at least as likely to be attacked with great viciousness as the Army or the Navy.

We are inclined to feel that the organization and immediate intensive training of civilian physicians and hospitals for care of war casualties and civilian defense is almost as important at this juncture as the obtaining of medical men for the armed forces. We hope they will shortly be given the serious attention they deserve. Medical Service, under O.C.D., should not become a social program or be left as a mere gesture on a paper.

George W. Cottis, M.D.

George W. Cottis, M.D., was born March 18, 1880, in Guelph, Ontario, Canada, and came to the United States at the age of eleven years. He supported himself as a Western Union messenger boy and later as an able seaman. At seventeen he entered high school, graduating a year and a half later.

He then taught district school in Genesee County, later entering Cornell University on a State scholarship. He graduated in Medicine in 1904, taking an internship at Bellevue Hospital, Fourth Division, after which he began the practice of medicine in Batavia, New York, as assistant to Dr. W. D. Johnson.

In 1912 he moved to Jamestown. Shortly after, World War I broke out. Dr. Cottis in 1916 applied for service in the British Army, serving as a member of the Harvard Unit in early 1917, in France. After America entered the War he was commissioned in the Royal Army Medical Corps as first lieutenant, and was stationed at base hospitals 22 and 26 at Camiers and Etaples, where he did surgical work. He was ordered in June, 1917, near Château-Thierry to reinforce a casualty clearing station, then served in French emergency hospitals, earning the rank of captain. Shortly before the Armistice he applied for a commission in the American Army, but the war came to a close before his transfer became effective.

Once again a resident of Jamestown, New York, Dr. Cottis became third vice-president of the Medical Society of the State of New York in 1919. About this time he also became a Fellow of the American College of Surgeons when this Society was organized, and was a member of the Founders' group of the American Board of Surgery. From 1920 to 1931 he served as delegate from Chautauqua County to the State Society, and was first vice-president of the Eighth District Branch, 1924-1927, becoming president of that body in 1926. At this time also he was a member of the Board of Censors of the State Society. In 1928 he was elected an alternate delegate to the A.M.A. in which capacity he continued to serve through 1932, acting also during the same period as vice-speaker of the House of Delegates of the State Society. In 1930, he was appointed by Governor Roosevelt a member of the New York State Health Commission on which body he served with distinction.

In 1933, he became a trustee of the Medical Society of the State of New York in which capacity he served through 1940, becoming chairman of the Board of Trustees for the year 1938. In 1941, he served as president-elect.

Dr. Cottis is also an honorary member of the Western New York Surgical Association, and chief of Emergency Medical Service in Jamestown.

Symposium on Trauma—Its Early Treatment

TREATMENT OF HEAD INJURIES

FRED W. GEIB, M.D., Rochester, New York

THERE is no set routine of treatment in these cases and the literature is full of variations of opinion. In the past two decades there has been a slow but steady recognition of certain fundamental therapeutic procedures. We will not take up in detail the neurological aspects of these cases, but will consider the immediate problems that confront the physician or surgeon who is summoned to the bedside of the patient.

Accident

The care of the patient at the scene of the accident is usually out of our control. By the time an ambulance arrives, he has been moved about by willing but medically ignorant laymen. Frequently he is taken to the hospital in an ordinary car because an ambulance is not available or because the well-meaning spectators think it is the proper thing to do. Fractures, spine injuries, shock, respiratory embarrassment, etc., mean nothing to the laity.

Actually, the patient should be wrapped in all available clothing to keep him warm, placed in a prone position very gently, and no attempt should be made to straighten crooked legs, etc. Wait until more expert help arrives before moving him. This all sounds very well to say and reads well but it is done only occasionally. We might as well accept the situation, because there appears to be very little we can do to change it. The laity exchange common sense for excitement at the scene of a serious accident.

Shock

The patient is brought into the emergency room. Serious cases are in shock and we direct our initial treatment to combating this. If the patient is critically injured and in desperate condition, it is expedient not to move him very much. Do not take off his clothes; just loosen them about the neck and waist. The temperature at this time is often subnormal; even if it is normal, the patient may be cold and clammy. Blankets and hot-water

bottles are placed about him. If he is vomiting, or bleeding from nose or mouth, he should be placed on his side if possible, to prevent aspiration. Likewise, if his color is poor, be certain that the tongue has not fallen back into the pharyngeal area. Suction should be available at the bedside in case he vomits, or blood and mucus fill the throat. Under this regimen, the greater percentage of these cases will recover from the initial or primary shock. We shall discuss supplementary remedy under the subjects of fluids and medication.

Oxygen

For the past two years, we have been using nasal oxygen in cases that show anoxemia and air hunger. It improves the blood oxygenation, as shown by the return of normal color, and reduces the marked respiratory effort. It appears to conserve the strength of the patient and may quiet him. Cerebral edema is increased by anoxemia and we think that oxygen has a definite usefulness in this type of case. If the patient is restless and does not tolerate a nasal tube, or if his nasal passages are filled with blood, we suspend a large funnel over his mouth. Thus he will receive oxygen because it is heavier than air and will gravitate into his mouth and about his face. Oxygen tents are too cumbersome and too complicated to use at this time. We believe that this is a valuable therapeutic measure in such cases, and helpful in general shock. Also, it is available at any hospital and easy to use. Six to 8 L. a minute is the average flow of oxygen used.

Injuries

Many cases of head injury are complicated by chest, abdominal, bone, and laceration injuries. Fractures can be splinted, pillows, and sand bags, or traction splints may be used, but no reduction or manipulation should be done. Immobility is all that is needed at this stage. It is important to check the abdomen and place a urinal in bed to collect a specimen when the patient voids. Test the urine for sugar, especially in older patients, because diabetes is not uncommon.

If the patient has a serious abdominal injury

To the Editor

You are doubtless familiar with the difficulties involved in getting camp physicians.

The Boy Scouts of Greater New York operate a number of camps around New York City, chief of which are the Ten Mile River Scout Camps which house 3,500 Scouts and leaders at a time during the months of July and August.

Normally we have used nine physicians, all of whom have been licensed to practice in New York State. Under the existing conditions we are prepared to adjust our plans to operate with as few or as many medical men as we can obtain and to compensate men as it becomes necessary.

In the past, considering most of the men have been interns, we have paid \$200.00 for the season of two months. We have adjusted our salary schedule upward so we will pay \$300.00 a season for the men we may be able to secure. Should

we be able to secure only a few men who would have to assume responsibility for the entire plant, we, of course, would have to be prepared to pay considerably above the scale as outlined.

While we would prefer to have men for the entire eight weeks' season, we will be glad to consider men for periods of two weeks or longer.

We feel that in view of the importance of Scout training and the camping experiences in preparing boys for their later service on behalf of the nation that the camps should be continued, and, of course, health education and the prevention of accidents and illness is a matter of primary importance.

Sincerely yours,

ALFRED C. NICHOLS, JR.
Director of Camping

Physician Wrongly Reported

To the Editor

Some days ago a booklet entitled "The Vassar Diet" was brought to my notice. It asserts that I have used or recommended this diet. Even the name of Mr. Vassar was unknown to me. A publication of mine is wrongly reported as referring to this diet and one-sidedly as to its contents which applied to another Viennese preparation that may or may not be similar to the Vassar diet.

A letter which I sent to the enterprise remained unanswered. It forbade any use of my name and requested the withdrawal of this or any similar advertisement from circulation.

Will you be so kind as to publish this letter?

Respectfully yours,

ALBERT MUELLER-DEHAM, M.D.

Compound Comminuted Fractures

All these cases are operative cases. Meticulous operating-room technic should be employed. Imbedded bone fragments must be removed and rough, depressed areas smoothed off and raised. Do not cut off the dural tags so long as they are attached. Smooth them out over the brain. Deeply imbedded fragments that cannot be seen from the surface should be left strictly alone and no probing done. More damage than good will be done by probing. Horax in a recent paper shows a very satisfactory way of removing such fragments, but the equipment and experience necessary may not be available. The important thing is to clean up the wound and try to close the skin flaps accurately. These cases are drained.

Infected Scalp Wounds

When a wound becomes infected, open it at the most dependent area and insert a soft rubber drain. Do not open it wide because the outer table may be exposed and dry out. Also, the skin edges will retract and leave a wide scar.

X-Rays

We are not concerned with the fracture of the skull, but with the damage to the contents of the skull.^{1,2} There is not one indication for an immediate x-ray of the skull. What are you going to do after you have it? It doesn't change the treatment one iota. The moving and the handling may shock the patient additionally and may rob him of the slim chance of survival. There may be the question of a depressed fracture. It is advisable to raise a depressed fracture when the condition of the patient warrants such an operation. We must consider the cases as semielective procedures. Glaser and Shafer have reported the end results in 91 patients who have had immediate, late, and elective operations for depressed fractures.³ They conclude that the surgery performed was not a factor in preventing sequelae. This is a splendid paper and is well worth reading by all of us who see head injury cases.

Fluids

A patient in shock may not respond to the quiet-and-warmth treatment. He may have lost a great deal of blood. Plain 5 to 10 per cent glucose and normal saline solutions, given slowly in amounts of 100 to 500 cc., are helpful but not sustaining. We use whole blood in severe hemorrhage cases and blood serum in

all other cases. Blood serum is available in our blood bank and can be given without regard to blood type. About 200 cc. of blood serum is given slowly and then more can be given as the condition of the patient demands. Hypertonic fluids are contraindicated in shock. All our severely injured cases are typed and matched routinely as soon as they are brought into the emergency ward. In this way valuable time is saved when the order goes out to give blood. Blood serum is of tremendous help and is becoming available for use in more and more hospitals. The severely injured and the unconscious patients are automatically put on "nothing by mouth" until the surgeon responsible for the case changes this order. This procedure prevents the patient from choking on or aspirating fluids.

Medication

Morphine, sedatives, and hypnotics are not used during the acute phases of the condition. They will mask the most important sign we have to observe—the degree of consciousness. Morphine also has a tendency to increase intracranial pressure.⁴ Morphine may be needed to ease pain and so decrease shock in cases that have other fractures. We have seen disastrous results following the use of adrenalin. Caffein hypodermically, or coffee by rectum, may be used safely. Time and time again we are asked about using phenobarbital when the patient is restless or having convulsions. If there is any chance of its masking symptoms, do not use it. In convulsive complications, use it, but remember that the question of a subdural or extradural hemorrhage must be ruled out. When we use it, we give only $\frac{1}{4}$ grain hypodermically at one time and repeat the same dose from time to time. This prevents overdosing the patient. Of course, in convulsive complications we give intravenously an initial larger dose of $\frac{1}{2}$ to 1 grain. Subsequent amounts are given as indicated.

Tetanus Antitoxin

All laceration cases receive tetanus antitoxin. When there are no shock or head symptoms, the antitoxin is given immediately. If the patient has been in shock, or has been unconscious, tetanus antitoxin is not given for twenty-four hours. If his condition is poor, and he is hovering between life and death for several days, we delay giving him the antitoxin during this time and may never give it. Practically all children have had horse-serum injections, and many are sensitive to it. Never give tetanus antitoxin in a head injury case

that requires immediate attention, and it is a life-or-death matter, then one must disregard the head injury and operate when the general condition will permit. Chest injuries in older people give us more concern than fractures. The nasal oxygen helps more than anything else in these cases.

Lacerations

All lacerations should be sutured as soon as possible. If the patient is in a critical condition, it is necessary only to prevent active bleeding by using clips, packs, or clamps. The scalp bleeding may be controlled by applying clamps to the galea and pulling them back over the skin edges. One must take great care in repairing the most trivial scalp wound to prevent infection or granulation, because one never knows whether a skull operation will not be necessary in a few hours or days. As soon as the patient improves and is out of shock, the following procedures are carried out.

Shave a large area about the wound, so that there is no chance for hair to drag across the wound. The hair along the border can be held down by using green soap solution. Take care that no hair strands are missed at the laceration edges.

The wound is then washed with tincture of green soap and irrigated with sterile saline. Small sponges can be used to wash the soap over the wound. Do not use cotton balls because they fray, and we all know how hard it is to find such blood-soaked strands in a wound. The procedure should be repeated until the wound is clean.

It may be necessary to anesthetize the area before anything can be done. A loose pack soaked with 2 per cent novocain is placed in the wound. If this is not effective, local may be injected into the scalp some distance from the cut edges.

So far very little discomfort has been suffered by the patient. The next step is to investigate every cranny, to pick out hair, dirt, and old blood clots, and cut out devitalized tissue. The skin edges should be trimmed of any suspicious-looking devitalized tissue. All this can be done gently and without much discomfort in many cases where local anesthesia has not been used.

What active antiseptics should be used at the time of closure? Sometimes we use ether as a solvent and antiseptic before closing the wound. The use of iodine and alcohol has been given up because both the substances are great coagulative agents. Water-soluble antiseptics can be used, and they do not produce

the pain that tincture-soluble antiseptics do. As a rule we use any one of the commercially prepared tincture antiseptics. We believe that it is the careful cleansing and débridement of the wound that counts rather than the effect of antiseptics.

If a bleeding vessel can be isolated, it is tied off with fine gut. We do not bury any suture material in the subcutaneous tissue. Silk or dermal sutures are used to close the skin edges and they are not placed any closer together than is necessary to get accurate close approximation of the wound.

If large skin flaps have been raised by the trauma, sterile sponge rubber can be placed in the outer dressings to produce mild constant pressure on the flaps. The wound is dressed daily to be examined for infection.

Small rubber tissue drains are used in wounds when it is impossible to clean them satisfactorily, and the drain is inserted at the most dependent portion of the wound. The drain is loosened at the end of twenty-four hours and slowly shortened so that it comes out on the third or fourth day.

In some cases it is not advisable to do very much to the wounds. It may be six or twelve hours before they can be completely cleaned up. Occasionally a patient receives first medical attention hours after the laceration has occurred. If the wound is dry and the soft tissues glazed, it is not advisable to close it without drainage. The longer a wound goes without closure, the more apt one is to drain it. If a wound cannot be closed immediately, try to keep it from drying out by approximating the skin edges with adhesive straps. This will give a better chance to close it tightly some hours later.

Compound Fractures

All compound fractures should be reduced to simple fractures as soon as possible. This applies to the skull too. We have been told to suture the pericranial tissues over the fracture line. Personally I have rarely seen enough tissue to use for such a suture. In plain compound fractures, follow the same procedure for repair of the wound as if the fracture did not exist. When blood or cerebrospinal fluids drain from an ear, the ear is washed with an antiseptic and a sterile dressing is applied to cover the entire ear. No antiseptic is put into the canal and no probing or otoscopic examination is done. No cotton is used to plug up the canal and dam back the fluid. All such procedures are liable to stir up an infection with a resulting meningitis.

are attached in a manner that permits snug application of the splint. If such apparatus is not available, a broad board may be passed beneath the patient without moving him and the head, trunk, and legs securely fastened thereto, or a ladder type of wooden splint may be used as a substitute. For the thoracic and lumbar injuries, the method of rolling the patient onto a stretcher, back up, as suggested by Stookey, is effective protection. Rough handling, lifting the patient by the shoulders and legs, or rolling, except in log fashion, are to be strictly avoided.

When admitted to the hospital all patients with physical findings indicative of spinal cord or nerve root damage should be placed on an air or sponge rubber mattress. The traditional board beneath a hard mattress is unessential, even though neural damage has not been sustained. If an injury of the cervical region is suspected, halter traction should be temporarily applied following the removal of the splint used during transportation. Supportive measures for the treatment of shock, if present, are to be instituted, and the patient should be made comfortable with narcotics, provided complaints or signs suggesting brain or visceral injury are not present. At this time a roentgen-ray study of the region under suspicion should be carried out with the patient in bed and without undue manipulation. If injury of the spinal cord or nerve roots has not been sustained, it is frequently advisable to keep the patient under observation for twenty-four to forty-eight hours before subjecting him to treatment directed at the reduction of the deformity. In some instances in which injury of the spinal cord or nerve roots is present, measures directed at a re-alignment of the damaged bone, particularly dislocations, are to be instituted as soon as shock or other complications have been brought under control.

Fracture, Dislocation, and Fracture-Dislocation of the Vertebral Column Without Injury of the Spinal Cord or Cauda Equina

Under this heading are included the fractures and dislocations uncomplicated by spinal cord and cauda equina injury and the cases of vertebral fracture associated with radicular pain resulting from encroachment upon the nerve roots at the intervertebral foramina. This latter group is relatively small, and usually the pain subsides following reduction of the fracture. Occasionally, rhizotomy may be required at a later period to

bring the pain under control. Needless to say, accurate diagnosis of all fractures and fracture-dislocations of the vertebral column cannot be made without detailed roentgenographic studies of the implicated area. Attempts to reduce suspected bony injuries before such an examination has been completed are not justified. Associated lesions of traumatic origin involving other structures must be given proper consideration, multiple injuries being frequently encountered. Once the issues have been evaluated and it has been determined that the major consideration is the reduction of the bony lesion of the vertebral column, the choice of method to be employed will depend on the vertebral level of the injury and the character of the deformity.

Cervical Injuries

Several methods have been devised for the reduction of traumatic lesions of the cervical vertebrae. We have given most of them a trial; however, the results have not been consistently gratifying. These procedures have been arranged in four groups for convenience of discussion. (1) The most conservative and the commonly employed one—traction by means of a halter—has given the least satisfactory results. Furthermore, this method is poorly tolerated by the patient; ingestion of food and fluids is difficult and the application of sufficient weight to effect reduction of the fracture often produces pressure necrosis of the skin over the lower jaw or occipital region of the scalp. (2) Stookey's method¹ of permitting the head to hang unsupported over the end of a firm mattress with the patient lying supine can be used only in fully cooperative patients. Even under ideal conditions the results following this procedure have not been uniformly good in our hands. (3) Taylor's method² of manual reduction under anesthesia has been successfully employed, but the inherent dangers during the manipulation and the difficulty in maintaining a complete reduction after it has been attained preclude its general applicability. (4) In our experience direct skeletal traction using the tongs designed by Crutchfield³ has given most satisfactory results (Fig. 1). Any desired degree of flexion or extension of the cervical spine may be obtained by appropriate selection of the site for exerting traction. Patients so treated are comfortable and may lie on either side or on the back, and the movements of the jaw are unrestricted. Rarely, the outer table of the skull is found to be soft; consequently, in such instances the weight for trac-

without doing a skin test. We have seen very severe reactions from horse serum that almost caused death, because of too early administration of the antitoxin after shock and unconsciousness. Likewise, in several cases, the latent reactions in very closely compensating cases have proved almost fatal.

We do not have the time to take up the routine orders, the use of lumbar puncture and of hypertonic fluids, and the indications for craniotomies. We have discussed these points in detail in a previous paper.⁵

Following extensive injuries to the skull and in osteomyelitis of the skull, there are cranial defects. These may be important from a plastic viewpoint, as well as from the consideration of lack of protection to the brain underlying them. Grant and Norcross have reviewed all the methods of cranioplasty within time memorial.⁶ The author has devised a vitallium skull plate operation and will now show a moving picture of the first operation performed.⁷

Summary

1. Treat the patient for his shock and do nothing that may increase shock.
2. Oxygen is very helpful for relieving respiratory effort and anoxemia.
3. Meticulous care should be given all scalp wounds.
4. Blood serum is of great help in cases of prolonged or severe shock.
5. Do not x-ray the skull immediately.
6. Bedside observation and constant vigilance through the first few hours may save what appears to be a hopeless case.

TREATMENT OF FRACTURES OF THE SPINE WITH AND WITHOUT NEURAL INJURY

JEFFERSON BROWDER, M.D., and RICHARD GRIMES, M.D., Brooklyn

THE recorded observations relative to the effect of trauma to the vertebrae, the spinal cord, and the nerve roots have established the important features in the diagnosis of these lesions in the vast majority of patients so injured. Several clinical entities have been delineated, and the pathologic physiology pertaining to each is fairly well understood. There still exists, however, considerable diversity of opinion concerning therapy, and it is with this aspect of the subject that the discussion in the present paper is concerned.

In an effort to present our experiences as objectively as possible, the cases of "fracture of the spine" which have come under our care at the Kings County Hospital during the past ten years have been reviewed. Although many methods of treatment have been tried, only those that have given consistently good results will receive detailed consideration. There were a total of 401 cases, 255 with fracture, dislocation, or fracture-dislocation, with-

out clinical evidence of neural damage; 125 with both bone and neural injury; and 21 with evidence of neural damage without roentgenographic findings of vertebral fracture or dislocation. The series does not include uncomplicated fractures of the transverse and posterior spinous processes of the vertebrae. Also excluded are those cases in which the spinal cord and nerve roots were damaged by penetrating foreign bodies. The mortality for the entire series was 16.9 per cent.

Treatment for all patients with clinical signs suggesting a vertebral column fracture should be instituted by the ambulance surgeon or others who may be required to assume the responsibility of transportation. All manipulations should be carried out in a manner that minimizes the possibility of increasing the deformity of the vertebral column. In order to accomplish this the spine must be splinted. A satisfactory method for immobilization of the cervical spine is the application of a broad aluminum splint to the patient's back, including the hips, constructed with an extension that has been molded to receive the occiput. Properly placed straps

Fig. 3. Adjustable apparatus for the support of the head and chest used during reduction of a lower thoracic or lumbar vertebra fracture and the application of the cast. The apparatus was devised in order to prevent stretching of the brachial plexus, a complication that we occasionally encountered in using the Watson-Jones or Davis method.

the vertebral column. All of these maneuvers have in common this principle—hyperextension of the vertebral axis. Whether this be accomplished slowly by placing the patient, lying on his back, across a convex surface, the curvature of which is gradually increased (Bradford frame, Roger bed, etc.) or by having the hyperextension more rapidly attained (Davis method, Watson-Jones method, etc.) depends on the type of lesion, the age, the status of nutrition, and the cooperativeness of the patient. The use of an extension frame of the Bradford type for cooperative patients usually results in satisfactory reduction. Many patients encountered in a city hospital are somewhat refractory; therefore, one is often obliged to resort to a more rapid reduction followed by fixation with a plaster cast. During the past seven years we have used a modification of the Davis method for the reduction of lumbar and lower thoracic bone injuries. With the patient under general anesthesia (rectal, intravenous, or some type of inhalation anesthesia) and lying prone on a fracture table, the distal one-third of both legs is well padded and tied together. The legs are then securely attached to a block and tackle arrangement swung from an overhead bar. The trunk and head are supported by a device (Fig. 2) constructed so that it does not interfere with the application of a cast after reduction has been accomplished (Fig. 3). With the patient in the desired position, the lower extremities are drawn upward in order to produce hyperextension of the lumbar vertebral column, while the operator, standing at the side, stabilizes the trunk with one hand

and applies pressure with the other over the site of the fracture or dislocation. In some instances it becomes necessary alternately to flex and extend the lumbar spine to break up an impacted fracture or to disengage a locked dislocation. Throughout all such maneuvers the patient is maintained in the suspended position and, following reduction, a full trunk plaster cast is applied. After a period of two and one-half to three months of bed rest, a spinal brace may be substituted for the plaster cast and the patient may be made ambulatory. Physical activity should be limited for another month. In the average case the spinal brace is worn for seven to eight months.

Fracture of the Sacrum

Injury of this part of the spinal column may be associated with fracture of other portions of the pelvic ring. There were nine fractures of the sacrum in the present series. The fragments were not displaced; therefore, bed rest for a minimal period of two months was the only form of therapy used.

Fracture, Dislocation, and Fracture-Dislocation of the Vertebral Column with Injury of the Spinal Cord and/or Cauda Equina

There were 146 cases in the series that presented clinical evidence of injury to the neural structure within the vertebral canal. In 125 cases there was roentgen-ray evidence of bone injury, whereas 21 showed no evidence of fracture or dislocation of the vertebrae although

FIG. 1. Appearance of the traction apparatus with Crutchfield tongs in position.

FIG. 2. Position for closed reduction of a lower thoracic or lumbar vertebral fracture.

tion should not be increased too rapidly, lest the pins break through the bone. Infection of the scalp or the skull has not been encountered, although in some instances the apparatus has been left in place for ten weeks. In all cases except one in which skeletal traction was employed the tongs were inserted shortly after the injury. The patient, representing the exception, had sustained a dislocation of the sixth on the seventh cervical vertebra six and one-half months previous to the institution of the treatment. A good reduction of the dislocation was obtained but not until the weight used for traction had been progressively increased to 50 pounds over a three-day period. Our experience indicates that skeletal traction should be continued for not less than four weeks and, in some instances, for a slightly longer period, particularly in dislocations. Although reduction may be effected in a few hours, secondary displacements frequently occur when the traction is discontinued too soon. Following removal of the skeletal traction, the neck should be immobilized by a brace or plaster cast for an additional five or six months, or occasionally longer according to indications. Satisfactory results may be obtained by using any type of cervical brace which adequately immobilizes the neck. Although it would be advantageous to completely support the head, as yet no apparatus accomplishing this has been constructed.

Thoracic Injuries (T_1 to T_{12} , Inclusive)

As shown in Table 1, fractures of this portion of the thoracic spine (the fixed part of the vertebral column) are relatively infrequent. If a mild compression of one of these vertebral bodies is limited to its anterior aspect, application of a fixation apparatus that immobilizes the thoracic and lumbar spine in a mild position of hyperextension without an attempt at

reduction will give satisfactory functional results. Injuries that have compressed the vertebral body to two-thirds of its normal width or more should be reduced using the Ryerson automobile-jack method.⁴ While this procedure for the reduction of a fracture of a thoracic vertebra is not uniformly successful, it theoretically offers maximum hyperextension of a relatively short segment of the spine. Associated fractures of the pedicles, laminae, or posterior spinous process of the involved vertebra are a distinct contraindication for the use of this method. With the patient lying in the supine position the head of the jack is placed directly beneath the posterior spinous process of the affected vertebra. Slowly the patient is elevated by the jack, while a mild counter pressure is applied over both the sternal and pelvic regions. Following adequate hyperextension, a fixation cast is applied incorporating the head of the jack. The latter is removed after completion of the procedure. The period of bed rest is variable; two weeks may be advisable for some, notably those of advanced years, whereas younger patients are kept in bed to advantage for a longer time. The total period of fixation in a hyperextended position, either by means of a brace of the Taylor type or a light plaster jacket, should not be less than four months.

Lower Thoracic and Lumbar Vertebral Injuries

The tenth, eleventh, and twelfth thoracic vertebrae are included with the lumbar vertebrae, since the treatment of fractures or dislocations implicating any of these segments of the spinal column involves the same principles. As obtained for bony injuries affecting the cervical region, several methods have been described for the re-alignment of deformities of traumatic origin involving this portion of

reason that all abnormal alignments of the cervical vertebral column associated with evidence of spinal cord injury should be corrected as soon as possible. This may be accomplished in fresh injuries within a few hours time by properly applied traction. This manner of reduction does not interfere with respirations that are already frequently embarrassed. The mortality in this group of cervical cord injuries was 51.1 per cent. The patients who survived were largely those presenting clinical evidence of partial interruption of the cord. Traction should be continued in these for the usual four- to six-week period. Immobilization of the neck by brace or plaster cast should then be instituted if the patient is physically capable of assuming the erect posture in bed or is to become ambulatory. As in simple fractures of the cervical vertebrae, immobilization of the neck is to be continued for a period of six to eight months.

Spinal Cord Injuries of the Thoracic Region (T₁ to T₁₂, Inclusive)

There were only 18 cases of injury of the spinal cord between the first and ninth thoracic vertebral levels, inclusive. If fracture is present, the treatment for this is no different from that outlined for uncomplicated fractures in this region, with the exception that a plaster-of-paris jacket should not be applied lest decubitus results. Following reduction, a blanket roll should be placed beneath the sponge-rubber mattress in a suitable position to maintain mild hyperextension of the vertebral column. If only a partial physiologic interruption of the spinal cord is present, a plaster-of-paris jacket or a suitable brace may be applied at the end of three months and the patient may be allowed out of bed. A spinal support should be worn for an additional period of four to six months.

Spinal Cord and Nerve Root Injuries of the Thoracolumbar and Lumbar Regions

In all, there were 39 cases of injury of the distal spinal cord and/or cauda equina. Many presented physical signs of a bizarre nature, difficult of precise interpretation. This was especially true in those instances in which the bone lesion involved the twelfth thoracic and/or the first lumbar vertebrae. In all cases, existing bone deformation should be reduced and the patient should be placed on a sponge-rubber mattress as suggested for lesions located in the thoracic spinal cord. The reduction of a dislocation may not be completely maintained by this method;

however, plaster casts should never be used when complete analgesia and anesthesia of the skin over the buttocks are present. Following some improvement in partial lesions of the cauda equina, it becomes necessary to apply a brace or a comparable means for the support of the back. Subsequent treatment of these patients will depend on the degree of recovery in function of the lower extremities.

Injuries of the Cauda Equina in the Sacral Region

There was only 1 instance of fracture of the sacrum with associated injury of the regional sacral roots. Treatment for the local lesion was bed rest on a sponge-rubber mattress.

Care of the Urinary Bladder, Bowel, Skin, and Skeletal Musculature

The treatment of vertebral fractures and the commonly associated spinal cord and nerve root injury would present relatively few difficult problems were it not for complications. Urinary sepsis, decubitus ulcers, and contractures of involved extremities are the outstanding ones. The appearance of any of these should be considered an indication that inappropriate therapy had been instituted or that proper measures had been carried out in an incompetent manner. Clinical evidence of irreparable neural damage should not deter the surgeon from inaugurating any treatment that may be an aid toward prolongation of life.

Urinary Bladder

There does not appear to be unanimity of opinion among those of experience regarding the treatment of the retention of urine which commonly follows spinal cord or cauda equina injuries. The majority of patients with this complication are catheterized, and the urine is drained away as soon as it is discovered that the urinary bladder is distended. This almost invariably leads to a cystitis and, later, pyonephritis, a single catheterization being sufficient to inoculate the bladder. The three methods that have been tried by us have been: (1) emptying of the bladder by intermittent catheterization, followed by irrigation with an antiseptic solution; (2) the use of an indwelling catheter with periodical irrigation of the bladder by means of a Y-tube arrangement, Munro's tidal drainage method, or McKenna's apparatus; and (3) manual expression of the urine by suprapubic pressure on the fundus of the bladder. The first of these methods should never be resorted to

obvious damage of the spinal cord or cauda equina had been sustained. In the instances in which no roentgen-ray evidence of bone injury was present and subsequent opportunity was afforded to examine carefully the area under suspicion at autopsy, there were findings indicating that the spinal cord had been damaged by a dislocated vertebra that had spontaneously reduced itself.

From a therapeutic point of view the major question that confronts the surgeon is whether the spinal cord or cauda equina has been completely or partially interrupted by the trauma. Partial physiologic interruption of the cord usually denotes *hematomyelia per se*. Complete interruption, on the other hand, usually signifies that the fiber tracts have been severely contused or this in association with hemorrhage into the gray columns. *Hematomyelia* may be limited to a relatively small zone, especially in the cervical region, with motor dysfunction of the forearms and hands and minimal, if any, clinical evidence that the commissural or long tracts have been involved. The hemorrhage may implicate the spinothalamic and pyramidal tracts predominantly in one-half of the cord, producing motor paralysis on the same side as the lesion and loss of appreciation of pain and temperature on the opposite side. Then, too, relatively large hemorrhages into the gray column bilaterally result in motor paralysis and a sensory dissociation somewhat comparable to that observed in *syringomyelia*. These traumatic syndromes have been more completely described in a previous communication.⁵ In any event, the function of the dorsal columns is the last to be abolished in *hematomyelia*. In the thoracolumbar region the pathologic alterations are frequently a combined spinal cord and nerve root injury. Seldom are clinical findings observed indicative of a pure *hematomyelia* implicating the lumbosacral swelling of the cord. Only 3 such cases have been observed in this series. The injuries of the cauda equina are varied, depending upon the degree of trauma inflicted.

Considerable importance has been attached by some to the presence or absence of a spinal subarachnoid obstruction as demonstrated by the Queckenstedt test in the case of spinal cord and cauda equina injuries. These authors have considered the presence of a block sufficient indication for laminectomy. However, we have observed both partial and complete obstruction of the spinal subarachnoid space released by re-alignments of the fractured or displaced vertebrae, while in other instances

the subarachnoid block has persisted for several days following reduction. Several cases of incomplete spinal cord lesions have revealed progressive improvement in function during a period when complete spinal subarachnoid obstruction could be demonstrated. For example, a patient with clinical evidence indicating a partial lesion of the cervical spinal cord of traumatic origin recently came under our care. Roentgen-ray examination disclosed no abnormalities of the vertebrae. A complete spinal subarachnoid block was repeatedly demonstrated, and this persisted for seven days, during which time there was a progressive improvement in function of the involved extremities. In brief, it is our opinion that the continuance of a demonstrable spinal subarachnoid obstruction after re-alignment of a fracture or fracture-dislocation of vertebrae is not in itself sufficient evidence to warrant the performance of a laminectomy. A subarachnoid block associated with clinical evidence of increasing spinal cord dysfunction is an indication for operation. Lastly, operation for the release of a complete spinal subarachnoid block coexisting with clinical findings indicating the presence of a complete physiologic interruption of the cord since the time of the injury may, on theoretic grounds, be indicated. In our experience, however, operation under these conditions is a futile gesture and has long since been abandoned. There were only 13 laminectomies performed in this entire series. Eleven of these were on patients with evidence of complete physiologic interruption of function of the spinal cord. No improvement followed operation and all 11 patients subsequently died.

Cervical Spinal Cord Injuries

In the present series there were 88 instances of injury of the cervical spinal cord, 72 associated with fracture, dislocation, or fracture-dislocation of the cervical vertebrae and 16 cases without bone lesion demonstrable by roentgen-ray examination. After considerable experience with several methods, it is at present our practice to apply direct skeletal traction as soon as feasible following admission to the hospital. While it is probable that the maximum narrowing of the vertebral canal occurs at the time of injury and that the disturbance of function in the vast majority of patients with spinal cord injuries is due to alterations within the cord itself, one cannot say that encroachment upon the lumen of the vertebral canal by a displaced vertebra may not exert some deleterious effect. It is for this

gesting spinal cord or cauda equina injury should be placed on an air or sponge-rubber mattress upon admission to the hospital. There is no substitute for this precautionary measure. Three or four hours on an average hospital mattress is sufficient time to produce ischemic changes in the skin and subcutaneous tissue overlying body prominences which frequently result in necrosis and ulceration. Even an equal distribution of weight to all cutaneous surfaces in contact with the bed, as obtains when a patient is on a sponge-rubber mattress, is not enough precaution to prevent decubitus sores. If complete functional interruption of the spinal cord or cauda equina is present, gentle massage of the skin, over bony prominences in particular, is to be carried out every four to six hours for the first week following injury. This may be accomplished without moving the patient by compressing the mattress with one hand and massaging with the other. The sacral region and the heels are the most vulnerable points and, therefore, require major attention. A bed cradle should be placed over the legs and feet lest the bed clothes produce necrosis of the tips of the great toes.

For the prevention of foot drop some type of support should be devised, constructed with a soft surface that comes in contact with the soles of the feet. It is unwise to apply adhesive plaster directly to the plantar surfaces and attach it to a traction apparatus as is frequently done in other conditions for the prevention of foot drop. After the patient had recovered sufficiently to permit passive movement of the paralytic extremities without producing pain in the back, full flexion, extension, and rotary movements of each implicated joint should be carried out twice or three times daily. Before and after these

manipulations, the skeletal muscles should be massaged without undue rubbing of the skin.

The treatment of the skin, joints, and skeletal muscles in patients with vertebral injury without evidence of neural damage is in no wise different from that accorded any patient confined to bed for a long period.

Summary

1. The case histories of 401 patients admitted to the Neurosurgical Service of the Kings County Hospital in a ten-year period (1930 to 1940) have been reviewed.
2. Methods for the immobilization of the spine during transportation have been suggested.
3. The use of skeletal traction for cervical fractures, the automobile jack for thoracic fractures, and the authors' modification of the Davis method for the reduction of fractures of the lower thoracic and lumbar spine have been described.
4. Fractures of the vertebrae and/or dislocations associated with neural injury should be reduced as promptly as the general condition of the patient permits.
5. The relatively infrequent indications for laminectomy are emphasized.
6. The management of urinary retention without catheterization has been outlined.
7. The use of the sponge-rubber mattress for the prevention of cutaneous ulceration is advocated.

THE TREATMENT OF INJURIES TO THE ABDOMEN

FENWICK BEEKMAN, M.D., New York City

THE subject of treatment of injuries to the abdomen is a large one, as it includes not only penetrating wounds but also other types of intra-abdominal injuries in which penetration has not occurred. Any one of the pelvic or abdominal organs may be injured and, as the treatment of each differs, it is necessary

for the surgeon in charge to have not only a knowledge of abdominal surgery but also ability in diagnosis, judgment, and operative skill. The diagnosis of these many conditions is of such great importance that it is difficult to entirely separate it from the treatment.

Today, with the large number of accidents on our highways, abdominal injuries have become much more common than they were in the past. Such injuries may be frequently

Clinical professor of surgery, New York University College of Medicine

since patients so treated almost unfailingly develop signs of urinary bladder and renal infection. Most surgeons elect to use the indwelling catheter in conjunction with irrigation. The Y-tube method presents but few technical difficulties and is probably the one most widely employed. Some degree of urinary tract infection, however, may be expected to accompany its use. Our experiences with Munro's tidal drainage and the apparatus of McKenna have been too limited to critically appraise their effectiveness. In an effort to eliminate the use of an indwelling catheter, we have extensively employed manual expression of the urine by suprapubic pressure. Furthermore, the use of this procedure facilitates the establishment of automatic urination. The method of manual expression of the urine by suprapubic pressure should be instituted by a competent person who is familiar with the procedure. Difficulty may be encountered in overcoming the spasticity of the internal vesicular sphincter during the first twenty-four to forty-eight hours following injury. The abdominal pressure required to initiate the flow of urine may produce some discomfort in instances in which the spinal cord lesion is incomplete or if the lesion has implicated the distal cord or cauda equina. The important details of the method as used by us are as follows: A mark with weak silver nitrate solution is made across the lower abdomen, halfway between the symphysis pubis and the umbilicus. Whenever percussion or palpation indicates that the fundus of the bladder has reached this level, manual expression of as much urine as possible is to be carried out. It cannot be too strongly emphasized that the urinary bladder must be emptied whenever the fundus reaches the mark on the abdomen and *not* at stated intervals. If the procedure is executed with care each time the bladder fills to the stated level, one can expect automatic emptying to take place sometime between the tenth and twenty-fifth day following injury. An indication that automatic micturition is about to become established is the ease with which expression of the urine is accomplished. Pricking the sole of an analgesic and anesthetic foot at the instant slight pressure is applied over the fundus of the bladder may also aid in initiating the urinary flow. Although the bladder cannot be completely emptied by this method, infection is extremely rare. If this complication does arise, one may resort to catheter drainage and irrigation. After the development of automatic micturition, criti-

cal attention directed toward the urinary apparatus is no longer required.

There should not be any question as to the desirability of establishing automatic emptying of the bladder in the management of urinary retention resulting from traumatic lesions of the spinal cord or cauda equina. The intelligent cooperation of the staff is a prerequisite if successful results are to be expected. Ideally, patients with such a dysfunction should never have a urethral catheter passed; however, there are some in whom retention of urine cannot be treated by any other method. An obese abdomen precludes the possibility of manual expression of the urine by suprapubic pressure. Elderly patients who may have thin vesicular musculature, possible diverticuli of the bladder, or urethral obstruction from hypertrophy of the prostate should never be treated for urinary retention of traumatic origin by this method. In this series the bladder was ruptured in 3 patients of advanced years before the lesson was learned. Lastly, urethral stricture of inflammatory origin may be encountered, requiring instrumental dilatation before suprapubic pressure for the evacuation of urine can be successfully instituted.

Rectum and Anal Sphincters

An injury of the spinal cord or cauda equina that is followed by urinary bladder dysfunction will almost invariably disturb the normal action of the rectum and the anal sphincters. If a severe degree of shock exists immediately after the injury, relaxation of the sphincters and total incontinence of feces may be present. More often, the external anal sphincter is flaccid, while the internal sphincter is in a state of complete contraction. It is unusual for a patulous anal canal to remain so for more than a few days, the eventual outcome of a "cord rectum" being a spastic internal anal sphincter with retention of feces. The easiest and most effective means of fecal elimination under these conditions is the irrigation of the rectum and distal sigmoid using a large rectal tube. It is advisable to carry out a digital examination of the rectum once a week to insure against fecal impaction. It is unwise to administer cathartics, since repeated involuntary fecal evacuations will ensue, necessitating repeated handling of the patient in order to change the bed linen.

Skin, Joints, and Skeletal Musculature

As stated in the introductory remarks, all patients with clinical evidence even sug-

gesting spinal cord or cauda equina injury should be placed on an air or sponge-rubber mattress upon admission to the hospital. There is no substitute for this precautionary measure. Three or four hours on an average hospital mattress is sufficient time to produce ischemic changes in the skin and subcutaneous tissue overlying body prominences which frequently result in necrosis and ulceration. Even an equal distribution of weight to all cutaneous surfaces in contact with the bed, as obtains when a patient is on a sponge-rubber mattress, is not enough precaution to prevent decubitus sores. If complete functional interruption of the spinal cord or cauda equina is present, gentle massage of the skin, over bony prominences in particular, is to be carried out every four to six hours for the first week following injury. This may be accomplished without moving the patient by compressing the mattress with one hand and massaging with the other. The sacral region and the heels are the most vulnerable points and, therefore, require major attention. A bed cradle should be placed over the legs and feet lest the bed clothes produce necrosis of the tips of the great toes.

For the prevention of foot drop some type of support should be devised, constructed with a soft surface that comes in contact with the soles of the feet. It is unwise to apply adhesive plaster directly to the plantar surfaces and attach it to a traction apparatus as is frequently done in other conditions for the prevention of foot drop. After the patient had recovered sufficiently to permit passive movement of the paralytic extremities without producing pain in the back, full flexion, extension, and rotary movements of each implicated joint should be carried out twice or three times daily. Before and after these

manipulations, the skeletal muscles should be massaged without undue rubbing of the skin.

The treatment of the skin, joints, and skeletal muscles in patients with vertebral injury without evidence of neural damage is in no wise different from that accorded any patient confined to bed for a long period.

Summary

1. The case histories of 401 patients admitted to the Neurosurgical Service of the Kings County Hospital in a ten-year period (1930 to 1940) have been reviewed.

2. Methods for the immobilization of the spine during transportation have been suggested.

THE TREATMENT OF INJURIES TO THE ABDOMEN

FENWICK BEEKMAN, M.D., New York City

THE subject of treatment of injuries to the abdomen is a large one, as it includes not only penetrating wounds but also other types of intra-abdominal injuries in which penetration has not occurred. Any one of the pelvic or abdominal organs may be injured and, as the treatment of each differs, it is necessary

for the surgeon in charge to have not only a knowledge of abdominal surgery but also ability in diagnosis, judgment, and operative skill. The diagnosis of these many conditions is of such great importance that it is difficult to entirely separate it from the treatment.

Today, with the large number of accidents on our highways, abdominal injuries have become much more common than they were in the past. Such injuries may be frequently

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.
Clinical professor of surgery, New York University College of Medicine.

complicated with those of other parts of the body, and it often becomes a difficult question for the surgeon to decide which should be attended to first. Penetrating wounds of the abdomen, both those due to gunshot and others that are the result of stabs, are found more commonly among the population of our large cities. In late years these conditions have also increased in number. Of course, in wartime they are by far the most common forms of abdominal injuries, though subcutaneous wounds of the viscera occasionally occur due to the impact of large, spent fragments of shells or the caving in of a house, dugout, or trench.

The management of a case of suspected intra-abdominal injury of the nonpenetrating type is most important, for operation should not be undertaken until a thorough physical examination and laboratory investigation have been completed. There is nothing to be gained by rushing the patient to the operating room, as was so often done in the past, and much harm may result.

It is now known that some types of abdominal injuries are better treated without operative intervention and, consequently, if a correct diagnosis can be obtained, the injured person may be saved from further shock. Moreover, the general condition of a shocked individual may often be improved and, by choosing the proper time for operation, the chances for recovery are increased. Consequently, the diagnosis of the intra-abdominal condition is the first and most important factor leading up to treatment.

Most deaths from internal hemorrhage occur rapidly following the injury, for the bleeding in these cases is usually from large vessels and, therefore, little can be accomplished by operation in order to save life. The hemorrhage in many cases of laceration of the spleen, liver, or kidneys soon ceases if large vessels are not torn, for a clot forms on the wound surfaces. This clot, however, may be displaced some time later and hemorrhage may again occur. Therefore, in many cases, operative intervention should not be undertaken until the clot has formed and the patient shows signs of improvement from the effects of the primary hemorrhage and shock. A patient whose systolic blood pressure is below 80 must never be operated upon, and it is far better to wait, if possible, until it has been raised to at least 90 before operation is undertaken.

If some hollow viscus has been ruptured, operative intervention is absolutely necessary

in order to prevent extension of infection from contamination of the peritoneal cavity. This, again, should not be attempted until the condition of the patient has improved sufficiently from shock.

Thoracic injuries may often produce abdominal signs that are similar to those of an intra-abdominal injury and, not infrequently, exploratory laparotomies are performed because of this. However, through proper physical examination and x-ray investigation, the injury within the chest can usually be demonstrated and further risk from an abdominal operation averted.

Retroperitoneal hemorrhage causes physical signs that are similar to those of intra-abdominal injuries. The hemorrhage in these cases may be the result of bleeding from a fractured pelvis, a ruptured kidney, or from small vessels in the lumbar gutters. The patient is necessarily shocked, the abdominal muscles are rigid and boardlike, and intestinal distention follows within twenty-four hours. The surgeon, therefore, is at first unable to decide as to the lesion or part that is involved. Undue haste to operate may result in a catastrophe; while, on the other hand, if a careful study is made during the time the patient is being resuscitated, a more exact diagnosis often may be reached. It is a common experience, I find, especially in injuries in children, to have the patient admitted to the hospital in deep shock with a rigid, boardlike, tender abdomen and at operation to discover no intraperitoneal injury but a retroperitoneal hemorrhage. The child would have done far better if the true condition could have been ascertained in the beginning, for it would have thus averted a needless operation. There are always, however, a large number of cases of abdominal injuries in which a preoperative diagnosis cannot be made and, in these, the surgeon must not hesitate to explore at a time when, in his judgment, the patient's condition has improved sufficiently to withstand operation.

An individual suffering from abdominal injury when admitted to the hospital is immediately placed between warm blankets so that the body heat may not be lost. If in a state of shock, the foot of the bed is raised. Nothing is allowed by mouth. Judicial use of parenteral fluids is of help in bringing the patient out of his primary shock. These, however, must not be given too rapidly, especially if venoclysis is used, since it may cause a rise in blood pressure and thereby increase internal hemorrhage. Normal saline solution may be used, but blood plasma or whole blood

are far better if obtainable. All of this, however, must be done with caution if hemorrhage has not been checked. Five hundred cubic centimeters of blood given to a shocked individual who is suffering from loss of blood can do no harm, but more may raise the blood pressure to a height that may increase the bleeding.

A complete physical examination, including rectal examination, is then made without, however, subjecting the patient to too much exposure or undue disturbance. Opiates, which are most useful in all cases of trauma, should then be given freely. Pulse rate and blood pressure readings taken every half hour are most useful as a means of informing the surgeon of his patient's condition. Frequent hematocrit readings to ascertain the concentration of the blood cells and the checking of the specific gravity of the blood by the use of the falling drop method are accurate means through which to differentiate between shock and internal hemorrhage. Though blood counts and hemaglobin readings have been superseded by these newer and more exact methods, these facts should nevertheless be obtained and recorded for future use. The blood of the patient must, of course, be typed and cross-matched to be prepared for transfusion. If there is the least suspicion of a rupture of the stomach or intestines, a roentgenogram should be obtained of the abdomen, with the patient in a sitting or standing position, in order to detect air within the peritoneal cavity. The absence of this roentgenographic finding, however, does not entirely rule out injury to some part of the intestinal tract.

Retroperitoneal hemorrhage is comparatively common following trauma of the abdomen in children. The diagnosis can be reached only by the method of exclusion and, consequently, in many cases surgical exploration becomes necessary when the child has recovered sufficiently from shock.

Wounds of the kidney may occur from rather trivial violence. There is usually severe shock, with marked tenderness in the costovertebral angle, spasm of the lumbar muscles, and hematuria, though gross blood in the urine is not always present. Most of these injuries heal without operative intervention. Therefore, expectant treatment should be instituted. Exploration, however, must be done if the hemorrhage continues, as exemplified by an increase of fullness in the flank accompanied by a steadily rising pulse rate; if there is persistence of the hematuria;

or if severe secondary bleeding occurs from the renal pelvis. Specimens of urine, therefore, should be saved in order that the surgeon may study his case by comparing their blood contents. If the kidney is badly damaged, an extravasation of urine into the retroperitoneal space is not uncommon. Here, operation must be done. The retroperitoneal space must be drained, and the kidney, or at least part of it, must be removed, depending upon the findings. Nephrectomy should be done through a lumbar incision and never through the transperitoneal route. But, before this is undertaken, the surgeon must be satisfied that the other kidney is functioning. Once the kidney is exposed there is little chance of saving it, and a nephrectomy is done, following which the wound is closed about a drain. A perinephritic abscess may develop following injury to a kidney. This, of course, should be drained in the usual manner.

Fractures of the pelvic bones cause large retroperitoneal hematomas in the pelvis which cause symptoms of an intraperitoneal injury. This injury may be accompanied by rupture of the posterior urethra or perhaps the bladder. Laceration of the bladder due to a fracture of the pelvis is usually through that part not covered with peritoneum, and an extravasation of urine supervenes into the space of Retzius. Whenever there is suspicion of injury to this viscus, a catheter must be passed in order to investigate. If the catheter's passage is obstructed in the region of the triangular ligament, a laceration of the membranous portion of the urethra should be strongly suspected. If the catheter enters the bladder and blood-free urine is obtained, injury to it can be ruled out. If, however, a scanty amount of blood-stained urine is obtained and, following injection of a sterile solution, only part of it returns, a wound of the bladder is almost certain. If there are no indications of injury to the bladder or the urethra, operative intervention is unnecessary. When, on the other hand, there is evidence of laceration of the urinary vesicle or of injury to the membranous urethra, a superpubic cystostomy should be performed as soon as the patient recovers sufficiently from shock, and appropriate measures should be taken to repair the damage.

The liver is composed of soft, parenchymatous tissue enclosed in a tense, fibrous capsule. Though partly protected from direct violence by the ribs, it is subject to compression that may cause a true rupture, the result of bursting force. The wounds, in conse-

quence, are often large and ragged; sometimes there is a single fissure, but more often there is an extensive stellate tear. There are marked symptoms of hemorrhage and shock. The abdominal signs at first may be localized but soon become general, and often death rapidly follows. There is a difference of opinion among surgeons as to the advisability of operating in all these cases of rupture of the liver. Those who advocate expectant treatment argue that when the tear in the liver is extensive it is impossible to obtain hemostasis by either suture or packing and, if a clot has formed, the manipulation at operation only tends to renew the hemorrhage. The other school of thought, on the other hand, advocates operative intervention following the resuscitation of the patient.

If a diagnosis of laceration of the liver can be definitely established, we think it is well to treat the patient expectantly. A diagnosis, however, is so often in doubt that exploration is frequently necessary. In this case the wound in the liver, if small, is sutured with heavy catgut on large, round, curved, blunt-pointed needles. Several rows of mattress stitches are used so that no dead space is left. The ends of the sutures should be tied, not too tightly, over small pieces of muscle obtained from the abdominal wall to prevent the stitches from cutting through. Large, stellate, fissure wounds can only be packed, and this is unsatisfactory as the gauze easily slips away.

Rupture of the spleen is treated satisfactorily by splenectomy. Though there have been case reports in which small lacerations have been sutured, this is not to be recommended. If the hilum of the organ is torn, death supervenes rapidly from hemorrhage but, if the splenic pulp is merely lacerated, the bleeding often ceases for a time after a clot has formed. All patients with ruptured spleens, however, must be operated upon, for it is well known that secondary hemorrhage from the splenic pulp is a common occurrence. Operative intervention should not be undertaken until the patient recovers sufficiently from shock.

Lacerations of the stomach and intestines are far more serious injuries than the others that have been described. These injuries generally occur when the organs are distended either after a full meal or when there is intestinal distention. They are usually the result of a severe, sharp blow upon the abdomen. Laceration of the large intestine is much more serious than that of the stomach or small intestine because of the greater infectious quality of its contents. The shock

to the patient is severe, and peritonitis soon follows from contamination. Early diagnosis and operative intervention are, therefore, of the greatest importance. The diagnosis may at times be made by means of the x-ray.

Surgical exploration is indicated, with but few exceptions, in all cases of penetrating wounds of the abdomen. These exceptions are small stab wounds of the lower part of the chest or lumbar region of the back. All penetrating wounds due to bullets or other missiles must be explored as soon as recovery from the initial shock has occurred. If the patient is first seen later than thirty-six hours following injury and if his condition is improving, a watchful waiting, expectant treatment may be established. Bullet wounds are far more serious than stab wounds, for the amount of intra-abdominal damage is greater and the extent of the injury cannot be nearly so easily estimated before operation. The apparent course of the bullet should, therefore, be investigated in each individual case, so that the extent of the injury may be established before operation. The direction taken by the bullet can usually be learned by finding the wounds of entrance and exit, for the course is generally a straight line projected between these two points. If no wound of exit exists, the bullet is occasionally found somewhere beneath the skin; otherwise, the position of its lodgment must be sought by means of the x-ray. When there is more than one bullet, the problem of ascertaining the course of each may be difficult. It should be remembered that the intra-abdominal contents may be injured by bullets that enter the body in regions far from the abdominal parietes, and it is only by establishing the direction of the missile that its progress can be correctly established.

Close range shotgun wounds are almost always fatal, since a large portion of the abdominal wall may be torn away by the explosion. At longer ranges there are multiple small penetrations from the shot. In the latter type of injury the treatment should be expectant, since it is impossible to trace and remove each small pellet.

The preliminary treatment of a patient with a penetrating wound of the abdomen is similar to that of one suffering from a nonpenetrating injury. It must always be borne in mind, however, when dealing with penetrating wounds, that damage to the bowel is probable and that progress of infection from contamination, among other factors, depends upon the time interval between injury and repair of the intestine. Full prophylactic doses of tetanus

antitoxin must be used in all such cases if caused by firearms.

If large vessels have been torn, the patient's condition fails rapidly and death may occur within the space of a few hours. The types of injury in which most help can be given are those in which the intestines have been perforated by a bullet; in these there is some hemorrhage, but the most important indication is the early closure of the perforations and, thereby, the prevention of widespread contamination of the peritoneal cavity.

General anesthesia, preceded by suitable premedication, should be used when operating upon any type of intra-abdominal injury. Spinal anesthesia is contraindicated because of the shock or hemorrhage. If a stab of the abdominal wall is only to be explored, it is permissible to use local anesthesia; but, if later it be discovered that the peritoneal cavity has been involved, a general anesthetic must be substituted.

When exploring a stab wound of the abdominal wall, the tract may be followed down by opening up each succeeding layer separately. This is necessary, since infections in these wounds are not at all uncommon and, since the muscles of the abdominal wall shift in position, the tract is not at all continuous. Having been opened widely, the wound is then lightly packed with vaseline gauze. If, however, it is discovered that the peritoneal cavity has been entered, a separate incision for its exploration can be used.

I repeat again that abdominal exploration must be done in all cases of penetrating wounds of the abdomen due to missiles. This is best accomplished by means of a long, paramedian incision through which the entire abdominal cavity can be explored. If all the abdominal contents are not then accessible, the incision may be enlarged by making suitable transverse or oblique extensions. The more experienced a surgeon, the longer are his incisions, for he well knows that through ready access to the abdominal contents he can the more easily accomplish his aims. After having obtained free access to all the organs within the peritoneal cavity, a systematic search is then begun in order to discover the extent of the damage. This may be far from where it was at first suspected because of the capacity of much of the abdominal viscera to shift in position. It should also be remembered that wherever a bullet has perforated a loop of intestine, there is necessarily a wound of exit and, frequently, more than one loop may be involved. A not at all uncommon experience

is to overlook an intestinal perforation, after carefully repairing others, and have the patient die a few days later from peritonitis. I believe that there is nowhere in surgery in which the old adage "more mistakes are made by omission than by commission" is more applicable than when operating upon gunshot wounds of the abdomen. The liver, gall-bladder, and spleen are first inspected. The stomach is then examined and, if a perforation is found on its anterior surface, there is surely one through the posterior wall. The duodenum is traced along its full extent and the pancreas is examined. Then the small intestine is investigated by beginning at the duodenojejunal junction and carefully following it down to the cecum. Each loop of intestine is gently delivered and after inspection returned again before the succeeding one is brought out through the wound. This method is far less shocking to the patient than when the intestines are entirely eviscerated at once. The large intestine is then followed through from the ileocecal junction to the rectosigmoid and, finally, the pelvic organs are examined.

Gunshot wounds of the liver are shattering in character and should be treated by packing about the surface opening. The track of the bullet must never be investigated or packed, since further unnecessary damage is produced. Cholecystectomy is performed when the gall-bladder is damaged.

Wounds of the spleen are treated by splenectomy. Those of the pancreas should be packed and drained to allow exit of the pancreatic secretions. The body of the pancreas can be exposed by entering the lesser peritoneal sac either through the gastrocolic omentum or the transverse mesocolon.

Bullet wounds of the stomach may be difficult to expose if high in the cardia. Wounds on the anterior surface are easily closed, using a double row of fine chromic catgut stitches. Those on the posterior surface, if near the greater curvature, can be exposed by entering the lesser peritoneal sac through any one of the avascular spaces in the gastrocolic omentum. If, however, the perforation of the posterior wall is high, it can be repaired only through a transgastric approach.

Bullet wounds of the mesentery seldom call for resection of the bowel, except when lacerated close to the intestinal border. Small hematomas of the mesentery may be disregarded; larger ones should be opened and the bleeding vessels secured. Isolated perforations of the intestines are closed as simply and quickly as possible with lines of fine

chronic gut sutures, taken through all the layers, and reinforced with peritoneal stitches. Resection of the intestines may be necessary when there are multiple, adjacent perforations, when the gut is severely lacerated, or when the circulation to a section has been impaired. Wherever there is a choice, however, this more serious operative procedure should not be undertaken, for it carries a far higher mortality rate than when perforations are simply closed. If the decision is to resect, the simplest and most expedient type of operation should be chosen. The form of anastomosis that has given the individual surgeon his best results is the one to be used, but the technic must be neither complicated nor time-consuming.

Wounds of the large intestine carry a far higher rate of mortality than do those of the small. If a perforation of this part of the intestinal tract is found, the surgeon should remember that there may also be a perforation through the retroperitoneal segment of the wall of the gut. To expose this the lateral leaf of the peritoneum should be incised. Whenever difficulty arises in closing perforations of the colon, the bowel contents may be side-tracked by performing a double-barreled colostomy proximal to the point of injury by simply pulling a loop of gut up through a small intramuscular abdominal incision and passing a glass rod through the mesentery beneath it. Sutures to fix the bowel to the abdominal wall are unnecessary and should not be used, since they may cause leakage of intestinal contents. The loop may be opened after twenty-four hours. If the damage to the bowel is great and speed is called for, the lacerated loop of large intestine may be "exteriorized." The small intestine, however, must never be so treated. Intestinal anastomosis by means of mechanical devices, such as the Murphy button, has long been abandoned as undesirable.

After having closed the perforation, attention is then directed to the contamination of the peritoneum. All intestinal contents, detached tissue, and blood clot must be systematically removed by means of a sucker or gauze sponges. Irrigating the peritoneal cavity is no longer advisable, since it spreads contamination more widely. The recent introduction of the sulfonamide drugs has placed a valuable means of defense against peritonitis in the hands of the surgeon. These drugs are now used extensively in combating peritoneal contamination, as well as peritonitis. The local use of sulfanilamide placed in

the peritoneal cavity has shown gratifying results in warding off peritonitis following contamination. It is used by placing 10 Gm. of the sterilized crystals in the abdominal cavity before the wound is finally closed. Drainage of the peritoneal cavity is thought by many to be unnecessary and undesirable if the toilet of the peritoneum has been carried out satisfactorily. However, leakage may occur, and it seems permissible to place a small cigarette drain so that it may establish a fistula if this complication should arise. The drain, however, must not be in contact with a line of suture. Drainage of the abdominal wall should always be done when intestinal perforation has occurred.

Extensive search for bullets is time-consuming and unnecessary and, unless the missile lies free within the abdominal cavity, its removal should not ordinarily be undertaken.

The late treatment in all types of cases of intra-abdominal injury is as important as the preoperative treatment or the technic used during operation. Early distention is often present, though infectious peritonitis has not developed. The patient should be constantly watched for the appearance of peritonitis or intraperitoneal abscess. Though paralytic ileus is the most common form of intestinal obstruction following intra-abdominal injuries, mechanical lesions are not unknown.

Complications of the respiratory system frequently occur; atelectasis appears during the first thirty-six hours and pneumonia later.

The intestinal tract of the postoperative patient, as well as that of the preoperative, must be placed entirely at rest. Nothing should be given by mouth. The patient should be kept absolutely quiet by means of frequent doses of morphine. Distention is combated by gastroduodenal drainage by means of suction. The Miller-Abbot tube is of advantage in many cases if it can be passed into the duodenum early enough. Cathartics or laxatives must not be used. Enemas or irrigation of the colon are only useful when the intestinal walls have regained their tone.

The most important problem during this period is the balancing of the body fluids and the maintenance of the protein level. Immediately after operation, shock and hemorrhage must be combated. This is best accomplished by means of blood transfusion. The laboratory is a most necessary guide in deciding whether to give normal saline, glucose solution, whole blood, or only plasma in building up fluid reserve of the body. Treatment with vitamins must also not be neglected.

THE TREATMENT OF HYPERTRICHOSIS BY ELECTROCOAGULATION*

CHARLES LERNER, M.D., New York City

THE problem of eradicating unwanted hair has taxed the ingenuity of man throughout the ages. Prior to the invention of electrical devices, there was no means by which hair could be permanently removed. In 1875 Michel,¹ an ophthalmologist, applied galvanic current in the treatment of entropion. Soon afterward, dermatologists began using the same method for hypertrichosis.

With the development of diathermy as a therapeutic agent, dermatologists had reason to believe that it might successfully be employed in removing hair. However, the limitations of the original diathermy machines appeared to thwart their hopes. Eitner² (1910) maintained the feasibility of this method and pointed out that the early failures were due to inadequate rheostat control.

The way in which diathermy was expected to produce epilation was by coagulating the tissue adjacent to the hair with a high frequency current of high voltage, just as the albuminous part of an egg is coagulated by cooking. This action differs from that of electrolysis, in which a direct current of low voltage is used to inactivate the tissue by breaking it down with the release of hydrogen bubbles and the formation of sodium hydroxide.

In the application of diathermy, if two large electrodes of equal size are placed on opposing surfaces of the body, the passage of current from one to the other is resisted by the tissues, thus producing an elevation of temperature in the tissues themselves. This is known as medical diathermy. If, however, one of the electrodes is made small (less than 1/2 inch in diameter), the resistance becomes concentrated in the tissue nearest the small pole and enough heat is generated at that point to coagulate the tissue.

Reasoning from this principle of shifting the area of highest resistance by reducing the relative size of one electrode, it might be expected that reduction of the small pole to a needle point and inserting it into a hair follicle until the papilla is reached would destroy

the hair-producing part of the follicle. It seemed that this might be accomplished without injury to the epidermis by a proper adjustment of the electrocoagulating apparatus.

This hope was first realized in the nineteen twenties by several experimenters in Europe. Bordier,³ of Lyons, is generally regarded as the first to demonstrate the success of the method. Certainly, he was a pioneer in the field and the most enthusiastic advocate of the new technic. Bordier maintained that the destruction of the hair root was due to coagulation of the vessels that supply it with nutriment. He advised the use of a tempered steel needle of suitable elasticity with a point 0.2 mm. in diameter and insulated over its entire length except at the point.

Following Bordier's success, his technic was tried by a number of other physicians, many of whom developed certain modifications of their own. Lanzi⁴ (1924) was able to confirm Bordier's conclusions that electrocoagulation was simpler, more practical, and less disfiguring than electrolysis for this purpose.

Katz⁵ in the same year reported his own experience but maintained that insulation of the needle was unnecessary, since the heat was concentrated at the point in any case, and by proper placing of the needle the papilla alone would be affected. He emphasized the small amount of pain produced by diathermy as compared with electrolysis. He also pointed out that scarring was the result of faulty technic, and when it did occur it was probably less than that caused by electrolysis. This conclusion was confirmed by Halla.⁶ These authors also emphasized the rapidity of the diathermy method by which about 50 hairs could be removed in ten or fifteen minutes as compared with an hour by electrolysis.

Rostenberg⁷ (1925) was the first in this country to recommend electrocoagulation for hypertrichosis. He used a current of about 80 milliamperes and recommended ten to twenty seconds for the removal of each hair. He attributed the high effectiveness of this method to the fact that the coagulation spreads over an area large enough to include destruction of the papilla even if the needle does not touch it. He also mentioned the reduction of pain, absence of scarring, and low percentage of recurrences.

In 1927 van Putte⁸ in Holland reported

*Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1931.

From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University.

¹In the interest of space conservation, for the purposes of publication, the illustrations have been deleted.

success with needles that he made for himself of watchmaker's wire. The steel was slightly heated to render it flexible and was then polished down to a point 0.1 mm. in diameter, increasing to 0.2 mm. at a distance of 5 mm. from the point. No insulation was used on the needle shaft. Van Putte applied 40 to 50 milliamperes of current for one second.

Mezei⁹ (1929) advocated the use of multiple insulated needles placed in a holder and each point separately inserted into each follicle in a given area. The current is then turned on and maintained until coagulation is completed. In order to determine the amount of current required, a test is made on one hair and the result is multiplied by the number of needles to be used. This multiple method is said to be no more painful than when one hair is removed at a time.

Reports by von Büben¹⁰ (1926), Kren¹¹ (1927), and Weidenfeld¹² (1927) further substantiated the observations of earlier workers as to the satisfactory results obtained by electrocoagulation. Von Büben noted the greater rapidity and reduced pain. Kren advocated the insulated Kromayer epilation-needle with the distal 2 mm. of surface unprotected. Weidenfeld used 3 milliamperes of current for three seconds and had minimal recurrence.

By 1928 electrocoagulation had become the method of choice in Europe, as indicated by Kende¹³ in review of the subject. Nor has the enthusiasm for it lessened since that time, as shown by more recent reports of Piérola¹⁴ (1933), Cumberbatch¹⁵ (1937), Cateula¹⁶ (1939), and Ducourtieux¹⁷ (1939).

Recognizing the fact that individual patients react differently to the treatment, Piérola recommended a preliminary removal of no more than 12 hairs to serve as a guide to the optimum amount of time and current to use for each patient. Cumberbatch advocated the use of a fine platinum-iridium needle. He also emphasized the need for care and dexterity and a thorough understanding of the technic in order to secure the best cosmetic results.

Apparatus

The current used is a highly damped oscillatory discharge, oscillating at a frequency above 1,000,000 cycles per second; it is obtained from a small portable, spark-gap type of high-frequency apparatus. The current density controlling mechanism is of a potentiometer type. An auxiliary switch provides a high and low current for other uses

so that the unit can be used for electrodesiccation and electrocoagulation of various lesions if desired. No milliammeter is required, since the calibrated scale on the current density control is a correct guide for desired dosage.

Technic

The technic concerning asepsis, positions of the patient and operator, and other details is essentially that of electrolysis. The needle is inserted with the usual precautions, and the current is turned on by means of a foot switch that should require only slight pressure. Utilizing a current of approximately from 60 to 75 milliamperes, the foot switch should be pressed for one second, three or four times, and the hair removed with forceps without resistance.

Comment

Most observers recommend the use of feeble current and prefer several applications of one or two seconds; this permits of greater exactitude and is better adapted for the various types of hair. My own experience with electrocoagulation so far has borne out the favorable reports of others. In order to overcome the fear of producing scars and to determine the optimum amount of current and time of application, I experimented on the volar surface of my left forearm. The hairs were clipped to a length of approximately $\frac{1}{2}$ inch from the skin surface so that the direction into the follicle could be more accurately followed. The intensities of current experimented with varied from approximately 125 to 60 milliamperes, beginning at the upper part of the forearm and decreasing as I proceeded toward the wrist, removing a few hairs with each decrease of current, carefully avoiding the removal of those that were close neighbors. I found that a current intensity of approximately 60 to 75 milliamperes was almost painless when applied intermittently for a total time of about three seconds.

Eighty-two clinic patients and 21 in private practice were subsequently treated by this method. Hairs were removed from the cheeks, chin, the upper lip, the breasts, and the upper and lower extremities. Only 6 patients of the entire number treated complained of some pain, but none stated that it was unbearable. Some developed immediate perifollicular erythematous reactions that were more intense than those of others and on investigation those patients were found to have some general vasomotor disturbance,

particularly hypotension. The impression was gained that all reactions on the face were generally less intense than those on the covered parts of the body. All evidence of reactions had disappeared within three weeks.

Although results with the insulated needle were not appreciably better than those with the uninsulated, the insulated needle should, in my opinion, be preferred because its use tends to give the operator a sense of security against scar production. It is important, of course, to be acquainted with the characteristics of the apparatus used and to test it on a patient or the operator himself to determine the optimum current and time. Needless to say one must be able to enter a follicle with the needle and contact the papilla. A skillful operator can thus remove approximately 200 hairs in an hour. It is inadvisable, however, to treat contiguous hairs or to make immediate repeated attempts in the same follicle after an initial failure.

In my opinion, the electrocoagulation method, though safe in the hands of an experienced dermatologist, could prove ineffective, destructive, and disfiguring if used by an amateur. Since it is really electro-surgery, its use should legally be limited to licensed physicians.

Conclusions

1. One hundred and three patients, 21 of which were private cases, were treated by electrocoagulation for the removal of superfluous hair.

2. The outstanding advantage of the method over that of electrolysis is speed; approximately 200 hairs can be removed by a skillful operator in one hour.

3. Pain is minimal and well tolerated when a current of approximately 60 to 75 milliamperes is used intermittently for a total of three or four seconds.

4. No scarring resulted from the treatment in any of the patients or on my own forearm on which a current of greater intensity was deliberately used.

5. No regrowth of hair has occurred after a period of six months.

6. From these observations I believe electrocoagulation to be the method of choice for the removal of undesirable hair and, in my opinion, will ultimately supersede electrolysis.

Discussion

Dr. Paul Gross, *New York City*—Dr. Lerner is to be congratulated on his fine paper for several reasons, of which I want to mention only one. He is known as an excellent dermatologist who has done a great deal of research work, particularly in radiotherapy and electrosurgery. His interest has been concerned with major problems of dermatology, in particular those of malignancies of the skin. The fact that he has devoted enough time to the improvement of the methods of removal of superfluous hair, proves that he has an understanding of the cosmetic, social, and psychologic difficulties and agonies to which women of all ages, afflicted with hypertrichosis, are subjected. I dare say this is a distinction for a modern dermatologist.

If I attempt to add a few remarks to his presentation, it is due to the fact that I have realized for many years that we dermatologists have neglected this field and actually have surrendered it to the layman with most unfortunate results, both to the patient and to the dermatologist. It was out of these considerations that I took up endothermy epilation as soon as Bordier published his technic in 1924.

My equipment consisted of a spark-gap diathermy machine, an x-ray timer permitting exposures up to one-twentieth of a second, and a milliammeter of the thermocouple type, with a scale from 0 to 100 milliamperes. After an experimental period, I was able to dispense with the timer and found the use of the bipolar surgical current of the spark-gap diathermy machine, with exposures of approximately one second, most satisfactory.

I can summarize my results in a great number of private cases as cosmetically excellent and permanent. There is no doubt about the superiority over electrolysis. I should like to give a few practical points that have guided me in the use of diathermy epilation.

1. It would be misleading and cause undesirable results if we assume that the concentration of the heat produced by diathermy forms

a cone with the tip at the needle point and widening downward. Actually, there is a concentration of heat around the needle point which decreases downward and upward, and the proper current will be the one that gives sufficient coagulation in an area around the point of the needle and no coagulation further up, particularly at the surface of the cutis. As can be seen, this postulate can hardly be fulfilled for the short-rooted lanugo hair. Nevertheless, it is possible to destroy even the papilla of the lanugo hair without visible scarring, showing the margin of safety of this technic.

2. The efficiency of the high-frequency current does not allow any compromise in accuracy and skill, particularly if the best cosmetic result is to be obtained. Recurrences are bound to be as high as in electrolysis because of the anatomic peculiarities of the hair follicle under the skin surface beyond the control of the operator's eye. This disadvantage is amply counteracted by the speed of the method. I have removed as many as 300 hairs in fifty minutes, and yet I consider not the speed itself but the time factor that permits the operator to perform the most important step of the operation—namely, the entering of the needle carefully, skillfully, and leisurely—as the greatest advantage. Electrolysis, requiring twenty to thirty seconds exposure for one hair, is sometimes an unbearable strain for the operator as well as for the patient. Diathermy epilation can really be a relaxation for the physician, after a busy office hour with talkative patients, and even after a treatment of fifteen minutes, one can see and feel that something has been accomplished.

3. Dr. Lerner, as well as other writers, mentions a certain milliamperage as a guide in selecting the strength of the current for diathermy epilation, but the current is so low that it will barely register on the ordinary low meter range of one to one thousand, of even a thermocouple instrument. It can only be measured accurately, as mentioned before, with a meter reading from 0 to 100 or 200 milliamperes. It is not absolutely necessary to be guided by the milliamperage meter. It is more important that the current

destroy the hair papilla in such a way that the hair can be easily removed without visible coagulation at the skin surface. This can be accomplished with a needle which is not insulated, but an insulated needle is preferable. For many years I have been using such an insulated needle but so far I have not found one with an insulation that would last the lifetime of the needle. Of course I insist on keeping my needles in an antiseptic solution, and I have found that the Bard Parker solution is one which will not affect insulation.

4. In recent years the short-wave diathermy has become a favorite, and superiority has also been claimed for it in diathermy epilation. I have tried several machines but so far have not reached a conclusion. I believe we should make a concerted effort to ascertain whether the energy output of a short-wave machine is as well suited for epilation as that of the spark-gap machine. My impression is that the current is not so flexible as that produced by spark gap.

In closing, I wish to say that I agree with all of Dr. Lerner's conservative presentation. That electrocoagulation is a method to be used by a physician only should be particularly stressed. This is admitted even by A. F. Niemoeller in his book, *Superfluous Hair and Its Removal*, advocating electrolysis as the safest and best method. Niemoeller quotes the editor of *Hygeia*, saying that "with diathermy epilation, there is more scarring, more discomfort and a larger percentage of recurring hair than there is with electrolysis, and that about the same number of hairs may be removed per hour by either method, if properly performed." May I say to this that in my experience exactly the opposite is true. In seventeen years I have never had the slightest complaint about scarring, and only a small percentage of patients discontinued treatment because of being discouraged by pain or lack of result. Many patients would only express one regret—namely, that I had not asked them to have themselves photographed before and after treatment so that other unfortunate victims of hypertrichosis could be encouraged about the success of this method.

What is the age at which a person may expect, according to averages, to live just as long again? At age 35 the expectation of life is itself 35 years, so that a white person at age 35 may expect, according to averages, to live to age 70, which happens to be the oft-quoted biblical "three score years and ten." No doubt it is this figure that Dante had in mind in the opening lines of his *Divine Comedy*, where he refers to himself as being halfway on the road of life. Writing this, supposedly in 1300, he was then 35 years old.

This halfway station, when a man's expectation of life is equal to his age, is somewhat variable according to changes in mortality, but much less so than the average length of life. According to mortality in the United States, the former figure has varied only from about 33 to the present 35—that is, by two years—in the last four decades, during which the average length of life has increased by almost 15 years.—*Statistical Bulletin, Metropolitan Life Insurance Company*

OBSTETRIC PROBLEMS ARISING FROM EXCESSIVE SIZE OF THE INFANT

KARL M. WILSON, M.D., Rochester, New York

THE birth of a fetus of tremendous size has been occasionally recorded, yet it is after all a rare occurrence and is cause for comment when it does take place. De Lee² records that in 64,000 cases on his service only 15 were born weighing more than 12 pounds or 5,443 Gm. and that all but 1 of them gave rise to serious dystocia. Hobbs and Scrivner³ in 1933 record 1 stillborn fetus weighing 7,700 Gm. (16.94 pounds) and giving rise to serious dystocia. Still larger authentic cases are on record but they are extremely rare.

Comparatively little attention has been paid to the problem of labor in connection with the fetus of unusually large size, and yet there are problems of an extremely serious nature to both mother and child which may arise because of the unusual development of the fetus. The difficulties that may arise are of such a nature as to play a real part in causing fetal and neonatal mortality, as well as maternal morbidity and mortality, and would, therefore, seem to warrant further study of the problems involved.

There are a number of well-recognized factors that may cause the excessive development of the fetus, as well as certain others concerning which we know little or nothing. Among the former, for example, may be included such factors as multiparity, prolonged pregnancy resulting in the postmature over-developed fetus, and diabetes. In general, also, though of course not always, the woman who is herself of unusual size tends to give birth to large children. It is also a matter of note that the woman who leads a sedentary life during the latter part of her pregnancy and who subsists on a diet too rich in carbohydrates will probably give birth to a child of unusual size. Various types of monstrosities should also be included. Of fetal factors that might influence the rate of growth of the child, for example, such as unusual activity of the pituitary body, we know practically nothing.

Provided the pelvis is of normal dimensions, the mere size of the fetus is unlikely to cause any serious dystocia unless it weighs 4,000 Gm. or more. So for the purposes of this study I shall present the outcome of a series of

infants in which the birth weight attained or exceeded this figure. This series represents observations on 406 women who gave birth to 495 infants weighing 4,000 Gm. or over. This latter figure represents 8.3 per cent of the deliveries occurring in the corresponding period of time, so it is obvious that the birth of babies of large size is a rather frequent occurrence. As would be expected, there were no multiple pregnancies in the series. From the above figures it is also apparent that the woman who has once given birth to a child of excessive size shows some tendency to repeat the process in subsequent pregnancies. Thus, 336 of our series of women each gave birth to a single child of excessive size, while 70 of them gave birth to 2 or more such infants, and 2 of them actually gave birth to 5 each.

Grouped according to the weight at the time of birth, this series is shown in Table 1.

TABLE 1

Birth Weight, Gm.	Number of Infants
4,000 to 4,499	399
4,500 to 4,999	82
5,000 to 5,499	11
5,500 to 6,000	3
Total	495

The particular points to be discussed include the effects of such large infants on the course of labor, the menace to the mother, the fetal mortality and morbidity and, finally, the procedures to be followed when confronted with this situation.

The effect on the course of labor in many cases may be slight; thus, in 76 instances the duration of labor was four hours or less, and 1 woman in the series delivered a living infant weighing 5,380 Gm. spontaneously after a three-hour labor. On the other hand, 45 women had prolonged labors of twenty-four hours or more, in each instance the prolongation being due to uterine inertia, probably caused by the unusual distention of the uterus.

Operative interference was resorted to in 85 instances or 17.7 per cent of all deliveries—not a particularly high incidence—while labor was artificially induced on 28 occasions, this being done to prevent further excessive development of the fetus (Table 2, following page).

When dystocia occurs in connection with an unusually large child, it is of interest to note,

Read at the Annual Meeting of the Medical Society of the State of New York, April 29, 1941.

provided the pelvis is normal, that the difficulty is seldom the result of an excessive size of the head but rather is to be regarded as shoulder dystocia, resulting from the great increase in the general bulk of the child's body with a corresponding increase in the circumference of the shoulder girdle. The course of events is often represented by a possibly rather easy birth of the head, and then difficulty is encountered on account of the large shoulders and body, this unfortunately occurring at a time when it is too late to resort to measures other than those that may well result in injury or death to the child. The factors involved appear to be the result of impaction of the shoulders in the pelvis and their failure to rotate or to be rotated artificially. For similar reasons, difficulty may also be encountered after the application of forceps, even outlet forceps. Several times we have had the experience of applying forceps when the head was at the outlet and yet, on making traction, advance failed to occur, the difficulty here being due not to the size of the head but to the resistance offered by the shoulders at the superior strait.

In addition to the dystocia factor, other difficulties may also arise on the maternal side, thus in 32 of our patients a postpartum hemorrhage of 600 cc. or more occurred, an incidence of 6.4 per cent. In each case the excessive blood loss was the result of uterine atony which, in turn, was probably the result of the extensive distention to which the uterus had been subjected. Another maternal accident was the occurrence of six third-degree tears, four in primiparas and two in multiparas. These occurred in spite of episiotomies performed before the extension of the head and, again, were definitely caused by the additional tension incident to the delivery of the large shoulders. Fortunately, all healed satisfactorily after primary repair. The incidence of puerperal infection was fortunately no greater than average, and there were no maternal deaths in the series.

Turning now to the results insofar as the fetus is concerned, we find that there were 24 who were born dead or who died within the first two weeks of life, representing a fetal mor-

tality of 4.8 per cent—not unduly high, perhaps, but yet definitely above the general clinic level of 3.5 per cent. Some of these fetal deaths doubtless could not have been prevented but, on the other hand, it must be admitted that a number of them could have been avoided had other procedures been followed at the time of delivery. The fetal death rate when considered in connection with the size of the offspring may be seen in Table 3.

TABLE 3

Birth Weight, Gm.	Number of Infants	Deaths	Mortality, Percentage
4,000 to 4,499	399	13	3.2
4,500 to 4,999	82	4	4.8
5,000 to 5,499	11	4	36.0
5,500 to 6,000	2	3	100.0
Total	495	24	

From the above figures, it is obvious that the fetal death rate increases rapidly for every 500 Gm. of weight above 4,500 Gm., becoming unduly high in those infants weighing 5,000 Gm. or more. In analyzing the possible causes for these fetal deaths, it is found that dystocia was the responsible factor in 16, or two-thirds, of the cases, and almost invariably the dystocia was due to the unusual size of the shoulder girdle and the generally increased bulk of the child's body. In the other 8 cases fetal death was due to factors in which the unusual size of the baby apparently played no part.

In addition to the fetal deaths, a number of birth injuries to children born alive also occurred, there being 6 examples of Erb's palsy, 1 of which was unfortunately permanent, and 3 fractured clavicles. Again these injuries were the result of difficulty in extracting the shoulders after the birth of the head.

In searching for possible causes for the occurrence of unusually large children in this series, a number of conditions that may have played a contributory part in connection with some of them are noted, while in many it is impossible to offer any explanation for the occurrence. Multiparity played an obvious part, only 88 of our series being primiparous women, while 114 pregnancies occurred in what the French call the "grande multipara"—that is, the woman who has undergone five or more pregnancies. Unusual size of the mother, particularly obesity, may have played its part in a good many instances, for in 142 women their nonpregnant weight was 72.5 Kg. (160 pounds) or more, 122 of these being multiparas. No figures are available on the size of the fathers, which might well play a part also.

Diabetes was not an important factor, since the series includes only 3 such women; while postmaturity, always a difficult matter to determine accurately, may perhaps have been a possible factor in 6 instances.

Advancing age of the mother has been suggested as a possible contributory factor, and this is to some extent borne out in our series. Thus, 206 pregnancies occurred in women over 30 years of age, 85 of them being over 35. On the other hand, 289 pregnancies occurred in women under 30.

The possible contributory factors of excessive size are tabulated in Table 4.

TABLE 4.—POSSIBLE CONTRIBUTORY FACTORS TO EXCESSIVE SIZE OF FETUS

Multiparity	407
(Grande multipara)	114
Excessive size of mother (72.5 Kg., 160 pounds, or over)	142
Diabetes	3
Postmaturity	6

Coming to suggestions as to the lines of procedure to follow in dealing with this problem, it would first seem that there are certain prophylactic measures that might well be given consideration. Under normal conditions of intra-uterine life, the fetus acquires almost its entire supply of body fat during the last two months of pregnancy. This is well brought out by the chemical analyses of Michel, as recorded by Bar.¹ For example, the body of a fetus weighing 1,024 Gm. at the end of seven months' pregnancy will contain 18.66 Gm. of fat, while the body of a fetus of average size (3,335 Gm.) at term will contain 392 Gm. of fat. It is also a common observation that in the case of the fetus of unusual size a considerable proportion of its increased weight is due to a marked increase in its body fat which, in turn, results in a considerable increase in the general bulk of the body without any necessarily striking change in the size of the head measurements. Another fairly well-established fact would make it appear that the chief source of the fetal body fat is to be found in

acental
known

points, it would appear rational to at least make an attempt to control the size of the developing fetus by restricting the supply of fat-forming foods during the last few weeks of pregnancy. This may be done by the so-called Prochownick diet in which the carbohydrate intake particularly is materially reduced during this period—that is, the last eight to ten weeks of pregnancy. One should

not expect too much from this procedure, but I have had some success with it, making use of it particularly in patients who give a history of previous difficult labors when the difficulty was apparently due to the unusual size of the baby. Adequate exercise and avoidance of a too sedentary life should also be advised. Induction of labor would also have a most decided place in the management of this condition when prenatal examination in the last week reveals a child of unusual size and, in particular, when the patient gives a history of previous difficult labors because of large size children. Furthermore, prolongation of pregnancy beyond the expected date of confinement should not be permitted. Cesarean section will also have a real place in the handling of these difficult situations. In our series a number of babies would undoubtedly have been saved had cesarean section been done, particularly in those 3 patients whose weight exceeded 5,500 Gm.

I find it particularly difficult to lay down specific rules as to when cesarean section should be performed. To adopt it as the mode of procedure for delivery of all unusually large babies would obviously involve the performance of a great many unnecessary operations, and yet, generally speaking, when it is chosen as the mode of procedure, it will have to be more or less elective. So often the difficulty in delivery arises after birth of the head when cesarean section cannot be thought of. A few generally applicable rules may be suggested, but they admittedly will not fill all the situations that may arise. If the pelvis be contracted to any marked degree, the decision is easy and cesarean section would be the procedure of choice. In our series only 12 women showed any degree of pelvic contraction, and the contraction in each instance was slight, so this was not a problem. In women who give a history of having lost 1 or more children as the result of large-child dystocia and who again present themselves with a large child at the end of pregnancy, elective cesarean section should be given most serious consideration no matter what the type of pelvis may be. Again, in women seen at the end of pregnancy with a child that appears to be of really great size, approaching 5,500 Gm. or over, the best results for both will in most instances be obtained by abdominal delivery. Often in these situations one may be easily misled by the fact that the pelvic measurements are normal and that therefore the pelvis will permit the passage of a baby of almost any size. Such, of course, is not the case and,

actually, it would require a pelvis of unusually large proportions—a justomajor pelvis—to accommodate such a child. Before resorting to cesarean section in such a case, it would be most desirable, if possible, to have a radiograph taken to assure oneself that one was not dealing with some form of monstrosity. In time, it is not too much to hope that prenatal radiographic measurements may be so perfected as to facilitate more accurate estimations as to the actual size of the fetus.

Abnormal presentations of large children also present a situation that may well warrant resort to cesarean section. Difficulty at delivery due to shoulder dystocia after the head is born too often resolves itself into some forcible means of extraction with no regard to the welfare of mother or child. De Lee² offers several suggestions that may at times prove of value in the presence of this emergency. He suggests first hooking a finger in the posterior axilla to draw the shoulder down or, failing this, to attempt a similar maneuver on the anterior shoulder. If unsuccessful, pass the whole hand into the birth canal, free the posterior arm, and draw it down and outside; or again failing in this effort, make a similar attempt to bring out the anterior arm, these procedures being carried out even at the risk of a fractured clavicle or humerus. If the

baby is already dead, cleidotomy or even evisceration may be necessary.

Summary and Conclusions

A series of 406 women who gave birth to 495 infants weighing 4,000 Gm. or over is presented. The gross fetal mortality was 4.8 per cent, but it was found to become progressively higher as the weight of the child increased and, unfortunately, was 100 per cent in 3 instances where the birth weight exceeded 5,500 Gm. The difficulty was almost invariably due to shoulder dystocia. In addition to the fetal deaths, a number of birth injuries such as Erb's palsy and fractured clavicles also occurred. There were no maternal deaths. Methods of procedure are discussed, including dietary measures, induction of labor, and cesarean section. The largest infants in the series were 2 who weighed 6,000 Gm.; both were born dead. The largest living child in the series weighed 5,410 Gm. and was delivered by cesarean section. The largest living child born spontaneously weighed 5,350 Gm.

CARE OF BABIES IN AIR RAIDS

In view of the general possibility of air raids on American cities, particularly in the coastal zones, the American Committee on Maternal Welfare regards it as important that American mothers understand and prepare well in advance for the task of protecting their babies. The committee is composed of the leading medical, public health, nursing, and hospital organizations of the country, and can thus speak with authority.

Aside from the immediate need of shelter from bomb explosions, the most important fact to keep in mind, the English have learned, is that the mother's mental attitude is baby's best guarantee against air raids.

"However frightened you may feel," the committee quotes from instructions issued by the British National Baby Welfare Council, "keep outwardly calm and unflurried, so that the child's confidence in your own protectiveness may not be shaken. Never speak of the raid in the child's hearing if you can avoid it. Mental impressions are formed very much earlier than most people realize. Many problem cases of the present day owe their condition to parents having talked continually in the presence of children about past and future air raids, about their own terror, and

the effect of this on the child. The following words are as true today as when they were written thousands of years ago: 'In quietness and confidence shall be your strength.'"

When the raid signal sounds, the first move should be in the direction of the nearest shelter. If there is no shelter, take the baby to the safest room in the house, or to a closet under the stairs or under a table or bed, so that he may be protected from flying debris, which presents the most frequent danger. Take with him garments enough to keep him warm according to the season, a basket or pillow on which he can lie, a first aid outfit in case of need; a toy to amuse him, his bottle of milk and a bottle of water, together with extra diapers and related equipment. The baby's ears should be blocked with cotton wool to minimize the effects of concussion, leaving plenty outside so that it may easily be withdrawn afterward.

If the raid should come while the baby is away from either house or shelter—for an airing in the park, for instance—find the nearest wall or ditch, however low, place the baby on the ground beside it, with pillows from the baby carriage or a heavy coat under and over him, and lie down beside him.

THE TREATMENT OF ETHMOIDITIS

JOHN R. HONISS, M.D., Rochester, New York

THE occurrence of uncomplicated acute catarrhal ethmoiditis parallels the occurrence of the ordinary common cold. One might well judge it to be one and the same thing. The ethmoid sinuses, because of their position, are the most vulnerable of the sinus groups, and it is probably impossible to have a real acute rhinitis without some involvement of the ethmoids.

If the infection is not severe and the patient's resistance good, the process lasts a few days. The nasal congestion subsides, the temperature becomes normal, the discharge thickens, and one may consider the attack ended. Local treatment, I believe, should be discouraged. Certainly, as emphasized by Peters,¹ the promiscuous use of the various nose drops flooding the market does more harm than good. It is safer to depend on sane general measures.

When, however, the acute symptoms do not subside in a reasonable length of time and there is evidence of increased pressure in the nose, together with lack of drainage and the presence of localized pain and headache with some temperature, then one is dealing with what may be called ethmoid retention.

General measures, with rest in bed, liquid and soft diet, and the application of mild silver preparations to the ethmoid area as a rule give satisfactory results. Aspirin, codeine, and hot towels to the face will often allay pain and pressure symptoms.

When these fail to relieve, one has to look for the complications of ethmoid involvement. Kelly² says: "The first one to consider is antritis." Localizing symptoms will put one on guard. There may be some frontal pain or tenderness, some tenderness over the anterior wall of the antrum, or perhaps pressure symptoms about the eye. There is apt to be some shadow on transillumination or x-ray.

I do not advocate washing a "hot" maxillary sinus, but when the usual conservative measures have not given the desired relief in a reasonable time and when we have waited for the local membrane congestion to quiet down, then I have no hesitation in making an exploratory puncture.

Several other writers on this subject have mentioned the frequent occurrence of antritis

with ethmoiditis and it is well to remember that possibility. There have been articles also on the danger of antrum irrigation. These dangers have been emphasized to such an extent that I am afraid a considerable number of practitioners think of antrum puncture as a last resort. If it is done carefully, with adequate anesthesia and with due respect for the parts involved, I fail to see the reason for apprehension. Many times the antrum wash helps to unlock the anterior ethmoid area; it also relieves frontal congestion. I find the antrum trocar and cannula one of the most valuable parts of my equipment.

Another method which has proved helpful through the years for a stubborn ethmoid is the argyrol tampon as recommended years ago by Dowling. Properly placed and repeated a few times, it promotes drainage. Owing to tightness in the upper part of the nose and ethmoid region, the placement of the pack may have to be preceded by the application of a small amount of 1 per cent neosynephrin or a 0.25 per cent ephedrine in physiologic salt solution or, in sensitive cases, a cocaine solution. The pack is left in place from fifteen minutes to half an hour. The virtue of the pack is not in its antiseptic qualities, but in its ability to draw the liquid elements from the tissues, thereby reducing swelling and promoting drainage. Gable³ states: "The colloidal silver preparations help by osmosis." That seems to be a logical explanation.

Still another approach for relieving pressure and unlocking the ethmoid is infraction of the middle turbinate.

The method employed by Shambaugh⁴ for draining the ethmoid is satisfactory in cases of low-grade chronic infection. "X-rays are taken to rule out frontal, maxillary, and sphenoid involvement. The nasal passages and nasopharynx are then cleansed with a sterile normal saline solution. The patient's head is then hyperextended in the Proetz position and the nasal passages filled with a 0.25 per cent ephedrine in physiologic salt solution. Alternate light suction and release of suction are applied with a hand bulb for from four to six times on each nostril, and if frank mucopus is obtained or blown out into a towel when the patient sits up, the diagnosis of ethmoid supuration is made. Several treatments of this type will usually give relief."

¹Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, May 1, 1941.

In hyperplastic or polypoid ethmoiditis, where most of the cell membranes have undergone degeneration and the middle turbinate is but a shell of its former self, the remedy is self-evident.

Many patients with this condition suffer for years without much complaint. Their sense of smell and taste may be very slight, but they come in because the nares are filled with polypi and nasal breathing is practically impossible.

In those well along in years and in those who for one reason or another will not permit a thorough exenteration, I have temporized in the treatment and have removed the polypoid masses with snare and forceps without going into the cells. Although one does not take any particular pride in this sort of work, it does give relief for varying periods of time and can be justified in certain cases.

When, however, the patient presents orbital symptoms, disturbances of vision, headaches, etc., then more complete work is indicated. This necessitates hospitalization. If the ethmoid area is crowded, owing to a thickened or deflected septum, a thorough resection should be done. After this has healed, the ethmoid work may be done through a wider approach and under better vision. The polypoid tissue is followed into the various cells and removed. Speed is not attempted. When one group of cells is removed, the area is sponged dry and the local anesthetic reapplied. This is done repeatedly until all cells within reach have been opened and the infected membrane removed. It is not an easy job. It takes time and patience, but I think thoroughness will be rewarded. Mithoefer⁵ notes that "the intranasal ethmoid operation done carefully is not done often enough." Complete exenteration in the true sense of the word is probably not often accomplished, owing to the varied anatomy of the ethmoid capsule. The turbinate is saved whenever possible. Sometimes only the posterior portion or the anterior tip needs to be sacrificed.

With the ethmoid area well cocaineized, the sphenoid sinus may be entered and drained if there is evidence of infection there. Infection in the ethmoid is not likely to clear up if there is a neighboring sphenoiditis.

After-care is important in that adhesions between the septum and turbinates and between the turbinates and the outer capsule wall must not be allowed to form, and the cases should be followed for weeks or months. If there is an accompanying chronic maxillary sinusitis, a radical Caldwell-Luc is done some time after the ethmoid operation.

It becomes apparent then that relief of ethmoid infection is not always a simple problem. It is usually associated with infection in one or more of the neighboring sinuses and it will not be cured until appropriate treatment is given these.

Twenty years ago very radical work in the ethmoid area was advocated. Some time later the pendulum swung the other way and an exceedingly conservative attitude prevailed. Does it not seem proper to assume that between these two extremes, perhaps, one may take a reasonable attitude? When symptoms warrant, thoroughgoing surgery, as in any other field, should be the procedure.

If a hyperplastic or suppurative ethmoiditis is associated with a severe asthma and if, as is sometimes the case, there is also an infection of the maxillary sinuses and sphenoids, one is faced with no small problem.

You have all seen the result of partial measures. As a rule they are disappointing to both patient and operator. The background of the asthmatic patient is apt to be marked by nervous instabilities and often definite allergic symptoms. Any simple operative procedure may temporarily give relief for a few days, only to be followed by a recurrence of symptoms.

Given this type of case, a thorough study should be made of the sinuses with every means we have. If, after this examination, it is found that besides a chronic ethmoiditis there is also a badly deflected septum causing impaction of the middle turbinates, a definite maxillary sinus infection, and also an infection of the sphenoids, we are faced with the problem of advising our patient. This means a resection of the septum at one time, the exenteration of the ethmoids and drainage of the sphenoids at another, and a radical Caldwell-Luc on the maxillary sinuses at still another time. I believe, as Crowe⁶ advises, that unless the patient is willing to go through this procedure, it is better to let the nose entirely alone.

Even with this radical procedure one cannot promise complete relief in all cases, but one can often predict fewer and less severe attacks as well as an appreciable amount of comfort.

In the March 1, 1941, issue of the *JOURNAL*, Grove⁷ reported the results of sinus surgery in 200 cases of asthma. He stressed the good record in those cases where complete surgery is done and he also emphasized that the results with the radical operation in the maxillary sinuses are twice as successful as those in which a window resection is done.

In summing up, I think it is fair to say that in the majority of uncomplicated ethmoid infections conservative methods will give very good results, but when the hyperplastic or suppurative ethmoid is encountered, with an accompanying sphenoiditis and antritis, then as complete surgery as possible should be done.

Discussion

Dr. Arthur Palmer, *New York City*—The treatment of simple acute ethmoiditis usually presents no great problem. Complications of this condition may be severe and require careful judgment in their management. Orbital cellulitis, seen more often in children than in adults, will frequently resolve without suppuration under nonsurgical measures. Chemotherapy is a definite aid in this connection. If suppuration occurs, external incision and drainage are indicated. As a rule, intranasal surgery is to be shunned in the presence of acute infections.

The care and cure of the patient suffering from chronic ethmoiditis will often tax the resources of the most skillful otolaryngologist. Medical treatment should place emphasis upon the value of prophylaxis, climate, diet—including vitamin balance and other general measures, as the use of autogenous vaccines, exercise, and hygiene—as well as upon the local treatment of the condition.

Briefly, the local treatment should be directed toward the maintenance and improvement of the physiologic functions of the nose and sinuses. The following are useful: nasal tampons saturated with isotonic ephedrine solutions, gentle suction combined with irrigation, infrared light therapy and at times long- or short-wave diathermy, the use of silver preparations locally, and desensitization in the presence of allergy. In all types of chronic ethmoiditis, except the hyperplastic with the presence of polyps, nonsurgical treatment should be given some weeks and perhaps months of trial.

When some general disease appears to be related to chronic sinus infection, conservative measures have been entirely satisfactory in a high percentage of cases. There is, however, a tendency to blame too many general conditions upon chronic sinusitis. If operation is decided upon, the surgeon must possess precise anatomic knowledge and manipulative skill and he must

proceed with greater caution than in any other type of nasal surgery. The importance of removing all diseased membrane in the ethmoid labyrinth has often been stressed by certain otolaryngologists. It is only rarely possible to remove all diseased membrane with safety. It is questionable, indeed, whether removal of all diseased tissue has ever been effected with the patient surviving the operation. While the intranasal approach to the ethmoid often proves satisfactory, the external approach is doubtless safer and should be employed especially when adjacent sinuses, as the antrums and frontals, are involved.

Ethmoiditis and Asthma.—In a study of 100 consecutive cases of bronchial asthma at the New York Hospital, the sinuses were found to be involved in 89 per cent, the antrums in 82 per cent, the ethmoids in 69 per cent, the sphenoids in 66 per cent, the frontals in 46 per cent of the cases. More than one group of sinuses was involved in 73 per cent.

With full recognition of these findings, we have nevertheless made it an inflexible rule never to perform an ethmoidectomy or any other type of sinus operation simply because the patient has bronchial asthma. We believe that the indications for operation are the same regardless of the presence of a bronchial asthmatic condition. Too often have radical surgical measures left the patient with an incurable atrophic rhinitis and scar tissue formation, with subsequent suffering from incapacitating head pains and many times little or no permanent relief of the asthma. In the presence of sinus disease, most patients suffering from bronchial asthma will be improved temporarily at least by treatment, whether it be medical or surgical. Few patients will be cured. Much the same policy in respect to surgery may well be applied in the presence of an allergic membrane in the nose and sinuses. If mechanical obstructions due to the presence of polyps, spurs, or deviated septums exist, they should be corrected surgically. We have proved to our own satisfaction that mechanical obstruction in the nose often has an unfavorable effect in that it aggravates the allergic or vasomotor disturbance of the mucous membrane.

Dr. Frederick J. O'Connor, *Syracuse, New York*—I have heard with interest and pleasure this paper of Dr. John Honiss. One perceives in it much that has not been written. Acute ethmoiditis occurs about as frequently as the common cold. When patients do not recover early there is some reason, e.g.:

1. Unusual virulence of the offending organism responsible (a) for the epidemic prevailing at the time, or (b) for the individual case, or a diminished resistance of the patient, who may be suffering from some general debility or convalescing from some other condition.

2. Some or all of the so-called normal anomalies of the ethmoid: (a) infundibular cells; (b) bulla frontalis; (c) concha bullosa; (d) a posterior ethmoidal cell, extending posteriorly and lying above the sphenoid sinuses, or a posterior ethmoidal cell extending into the maxillary sinus, creating the so-called double maxillary sinus; (e) extension of the foveola well into the roof of the orbit.

A rhinologist, to be safe, should fortify himself by being thoroughly familiar with some or all of the following works, Zuckerkandl, Onodi, Hajek, Warren B. Davis, and with the specimens that Mosher has collected in his laboratory.

3. What one likes to think of as physiologic anomalies: (a) regular, honest hay fever, which occurs regularly season after season and is no more than that; (b) hay fever and infection—there is no reason why a hay-fever sufferer might not also have an ethmoidal sinusitis; (c) allergy to the organism causing the ethmoidal sinusitis. Again the rhinologic problem must be studied on an endocrine basis.

Treatment

1. Preventive: (a) increasing body resistance—vitamins, cold vaccines, sun lamps; (b) isolation of cases to prevent spread; (c) chemotherapy—sulfadiazine.

2. Symptomatic: (a) treating symptoms as they arise (headache, general malaise, nasal obstruction)—shrinking sprays. Dr. Wishart

of Toronto, Canada, is a strong advocate of systematic, thorough shrinking.

3. Heat: (a) short wave—inductotherm; (b) hot or cold compresses; (c) steam.

4. Operation: I feel that so long as one's hand is not forced by an apparent impending extension of the infection into the surrounding areas, one would do well to be slow to operate. Lyman Richards advocates caution, although he says that many times it takes courage to wait. One should never let his operation be more extensive than the condition demands. Exenteration of the ethmoid is done much less frequently today than it was twenty-five years ago. There are three surgical approaches to the ethmoid—all three have their advocates and in the skilled hand all three give good results: (a) the intranasal ethmoidectomy; (b) the external ethmoidectomy; (c) the transantro ethmoidectomy.

Concerning nasal operations: Mr. Norman Patterson said: "Operations on the nose should when possible be avoided." Extensive operations are frequently performed when there is no possible justification for them. It is often the case that the patient who would have made a good recovery from the disease never recovers from the operation. Dr. Mosher has called exenteration of the ethmoid, "the easiest operation that could cause a patient's death."

In conclusion, please let me leave with you Dr. Shurley's three "guardian angels": (1) common sense; (2) surgical judgment; (3) study of the individual.

SAVE THE PIECES!

In this day of flying missiles and bodies hurtling through space, injuries to the external ear are quite common. When an ear is nearly severed, it is often surprising how promptly it will heal when kept clean and accurately and promptly sutured in place. The ears have it, when it comes to circulation! But if all or part of the structure is detached, chances of success are negligible.

In such an instance, however, as with finger tips or ends of noses, save the piece! Skin it clean and tuck the cartilage into a subcutaneous pocket upon the abdominal wall. Here it will remain clean and viable, to be invaluable in subsequent reconstructive surgery. After the accidental wound has healed and the defect is established, the cached cartilage may be inserted

about the meatus through a postauricular incision and pressure dressings applied. After several weeks or months the cartilage and overlying skin may be raised from the side of the head, as a flap pedicled ventrally. Denuded surfaces may be covered with a free split skin graft.

Restoration of maldeveloped or mutilated ears is notoriously unsatisfactory. Utilization of maternal ear cartilage grafts in the former has proved to be singularly helpful, cartilage and cornea being the two human tissues which can be successfully transplanted from one individual to another. Prompt preservation of the patient's own ear cartilage, in cases of accidental severance, will save future time and trouble. And the patient will be grateful for a superior end result.—Rocky Mountain M.J.

A doctor stopped his car on a country road and asked a little boy how far it was to Russellville.

The little boy answered: "It's about 35,999 miles the way you're going, but if you turn around it ain't but three."

Diagnosis

CLINICOPATHOLOGICAL CONFERENCE

March 26, 1942

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

History

This was the fourth Bellevue admission of a 73-year-old white man of Greek extraction, who entered the hospital on January 9, 1942, with chief complaints of cough and anorexia of three months' duration. For two months this cough had been productive of moderate amounts of mucopurulent sputum. For two weeks slight blood-streaking was present. Twelve years prior to this admission, the patient's weight was 254 pounds; one year before, it was 180 pounds, three months before, 178 pounds, and at the time of this admission, 153 pounds. Some hoarseness had been present for three months. Increasing weakness accompanied these symptoms. The patient's statement that he had had difficulty in swallowing was not borne out by observation in the ward. The only other complaint was constipation of two months' duration. The character of the stools was not noted. No nausea, vomiting, eructations, or diarrhea was noted. The genitourinary system was negative except for nocturia (two to six times nightly).

The past history revealed that the patient had had a gallbladder operation thirty years before, with postoperative adhesions. Five years before, he had been admitted to the Neurological Service for weakness of the left hand. Fibrillary twitches of the left hypothenar muscles and of both gastrocnemii were reported. X-rays showed early hypertrophic osteoarthritic changes. The clinical impression was "syringomyelia, midcervical region." Upon discharge from the hospital, paresis of this extremity improved, and no further complaints about this condition were brought forth. Other admissions to Bellevue Hospital had been for (1) acute otitis media, (2) phimosis.

On admission in the present instance, the temperature was 99.6 F., pulse 64, respirations 20, and blood pressure 170/90. Physical examination revealed an elderly white male appearing chronically ill, hoarse, almost aphonic, but neither dyspneic, orthopneic, nor cyanotic. The skin showed no petechiae,

purpura, or jaundice. There was a hard 2.5-cm. fixed nodule above the right clavicle, and a movable hard nodule in the right axilla. A few small left posterior cervical nodes were present. The head and scalp were negative. The pupils were equal, regular, and reacted to light and accommodation. There was no nystagmus or palsies. The sclerae were white, the conjunctivae pale. Examination of the fundi showed sclerotic vessels, but no exudates, hemorrhages, nor arteriovenous nicking. The ears, nose, and throat were negative. Direct laryngoscopy did not reveal any pathologic changes except for thickened, reddened vocal cords. The trachea was in the midline; there were no tracheal tug and no dilated neck veins, and the thyroid was not palpable. The chest revealed increased anteroposterior diameter with scoliosis to the left. The lungs were resonant throughout. Over both lower axillae, and posteriorly at the very base, a few medium moist and coarse rales were heard. The heart was not enlarged; A_2 was greater than P_2 . There were no thrills or murmurs. Regular sinus rhythm was present. A right rectus incisional scar was present in the abdominal wall. A hernia was present at the site of the incision. The right lobe of the liver could be felt 5 inches below the costal margin. The spleen was definitely palpable. There was no clubbing, cyanosis, or edema of the extremities. The pedal pulses were of good quality. Rectal examination revealed a normal-sized prostate with a small hard nodule high up on the right lobe. The reflexes were physiologic.

Laboratory Findings

The urinalysis on admission showed a specific gravity of 1.026, acid reaction; the remainder of the findings were not significant. Fasting blood sugar on January 21 was 211, on February 2, 181, and on February 18, 164. Daily urines (collected), taken two hours after meals, were reported as showing 0-2 plus glucose. The blood nonprotein nitrogen was 36, and the Wassermann was negative. The electrocardiogram showed no findings of diag-

nostic significance. The red blood count was 5,300,000, with 90 per cent hemoglobin, the white blood count 8,700, with 78 per cent polymorphonuclears. The cells were normal.

X-ray Reports

An esophagram showed no organic lesion of the esophagus. Extrinsic pressure of the mid-third of the esophagus was observed in the left oblique and was due to aneurysmal dilatation of the aorta at the base of the aortic arch. The heart was not enlarged. There was slight widening of the arch of the aorta. There were interstitial changes at the roots of both lungs and thickening of the pleura on the right (January 13).

Gastrointestinal Series

Examination revealed no evidence of any intrinsic lesion of the stomach or duodenal bulb. In the third portion of the duodenum there was a rounded, translucent area associated with an abnormal spreading of the mucosal folds. "My opinion [Dr. Buckstein] is that we are dealing with a tumor of the duodenum with partial intussusception" (February 2). A repeat x-ray on February 5 revealed identically the same findings as previously seen.

After initial work-up on the Surgical Service, before the gastrointestinal series was done, the working diagnosis of bronchogenic carcinoma was made. The impression of the chest consultant was that the pulmonary symptoms were due to chronic bronchitis and laryngitis. Essential hypertension and diabetes were secondary diagnoses.

Course

The patient's hoarseness and cough showed improvement. The blood-streaking disappeared. The diabetes was well controlled on a C 130 low-fat diet without insulin. The patient was transferred to the Medical Service with a radiologic report of possible duodenal neoplasm, and transferred back to the Surgical Service for consideration for exploratory laparotomy. There, however, he went rapidly downhill, and, upon 1,200 cc. of fluid before operation, went into pulmonary edema. Despite digitalization, circulatory failure persisted, and the patient expired on the forty-seventh hospital day.

Clinical Impressions

DR. ZACHARY SAGAL (February 2): Globular dilatation, of the size of a pigeon's egg, in the third portion of the duodenum. While

the roentgenologic appearance suggests an intussusception, I cannot conceive of this taking place in a segment of duct which is retroperitoneal. Carcinoma is a better bet. Patient has a hard node above the right clavicle which may be metastatic.

DR. ALLAN R. ARONSON (House Note): Because of hepatomegaly and splenomegaly, as well as relative frequency of different types of duodenal tumors, I believe lymphosarcomatosis is the most likely diagnosis.

DR. MAX TRUBEK (February 2): As suggested by Dr. Aronson, because of splenomegaly, we may be dealing with a lymphomatous type of tumor amenable to radiation therapy.

DR. DORAN (surgical consultant): Probable metastatic malignancy from the duodenum.

Discussion

DR. ZACHARY SAGAL: The patient was admitted to the surgical wards because of dysphagia, with the possibility of carcinoma of the esophagus as the cause of this underlying symptom. However, his behavior in the ward did not bear out this complaint. The cough with the blood-streaked sputum improved and gradually disappeared, as well as the subjective and objective hoarseness. Incidental findings were diabetes mellitus, which was easily controlled on diet alone, and moderate hypertension. The neurologic diagnosis of syringomyelia was made five years prior to admission. There was no evidence of the disease on the patient's last admission. Important among the patient's symptoms were increasing weight loss, nausea, anorexia, and asthenia. Biopsy, of course, of the hard supraclavicular and axillary nodes would have been of immense value. Hepatomegaly and splenomegaly along with the above-mentioned nodes were the significant findings. The small nodule on an otherwise normal prostate may have been the seat of neoplastic changes, but that is not likely. X-ray revealed a large filling defect (globular) in the third portion of the duodenum. I cannot conceive of intussusception taking place in the third portion of the duodenum, which is firmly bound down by the peritoneum. In the ward, I mentioned the faint possibility of a large biliary calculus ulcerating into the duodenum. This, however, cannot be correlated with the other findings as cholecystectomy was done thirty years ago. The gastrointestinal series, except for the duodenum, was negative. A barium enema was not done. I believe that both right- and left-

sided large bowel malignancies with metastases can be ruled out. Right-sided malignancy is usually accompanied by anemia, which was not present in this case; left-sided malignancy by obstructive signs and symptoms, which also played no part here. Cirrhosis of the liver with splenomegaly must be considered in the differential diagnosis, but this cannot explain the whole picture. Primary carcinoma of the liver is a rare lesion that we should think of, but the rigid criteria for this diagnosis exclude it here. The supraclavicular metastatic nodes caused bronchogenic carcinoma to be considered a possibility, but it will be noted again that the pulmonary signs cleared, and the roentgenologic evidence was against it.

In retrospect, the presence of nodes, the splenomegaly, the widening of the base of the heart, make one think that malignancy originating in the lymphatic system is the most likely diagnosis. Thus my first diagnosis is a lymphoma.

Leukemia is partially ruled out by the normal blood count. If an aleukemic leukemia had been present, the patient should have had a severe anemia. It is also possible, in view of his previous neurologic symptoms, that the primary source of this lesion was a neoplasm of the central nervous system.

The mode of exitus is difficult to explain. The heart was not enlarged; only moderate hypertension was present and the electrocardiogram showed no significant changes. It is hard to conceive that 1,200 cc. of fluid could have precipitated pulmonary edema. A gradual onset is more likely, and lymphomatous infiltration into the myocardium is again a possibility to be thought of.

DR. EMANUEL APPELBAUM: I believe that some form of lymphosarcoma is the most likely diagnosis. Primary carcinoma of the duodenum should have been considered, but its rarity in the third portion would tend to rule this out. The enlarged spleen is of importance and suggests that the lymphosarcoma is of the giant follicular type.

DR. ARNOLD KOFFLER: The x-ray report of partial intussusception makes me believe that the third part of the duodenum was abnormally free or that the tumor originated from a more proximal portion of the duodenum. Very little attention has been paid to the fairly marked compression of the esophagus. Aneurysmal dilatation as well as mediastinal glands may well have produced this picture.

DR. MENNASCHE KALKSTEIN: In view of the multiple lymph node enlargements, the

splenomegaly, and the mediastinal pathology with esophageal compression, which is most likely due to enlarged mediastinal lymph nodes, a lymphogenous process is the most likely diagnosis. However, the possibility of a carcinoma arising in a bronchus with diffuse lymphatic and hematogenous spread has not been eliminated. Bronchoscopy was not performed. A small tumor can be readily overlooked even in the presence of widespread metastases. Although there is no direct evidence in this case, the thyroid as well as the bronchi should be suspected as the possible source of neoplastic dissemination to the retroperitoneal lymph nodes. If this is the case, splenomegaly may be the result of an old malarial infestation in a Southern European.

DR. LOUIS F. BISHOP: There was no definite evidence of cardiac disease. Other causes of marked moisture in the lungs could have been present. Hypostasis and mediastinal compression may have been factors in producing this picture.

Pathology

DR. ROGER W. STEINHARDT (Gross Pathology): On section of the chest, some free fluid was encountered in both pleural cavities, but the striking finding was the mediastinal lymphadenopathy, which extended from the hilar region of the lungs to well above the arch of the aorta. These nodes were firm, homogeneous, matted, and surrounded, but did not obstruct the trachea, esophagus, and aorta. They hugged the major branches of the aorta and could be traced to the supraclavicular nodes seen clinically. The heart was normal in size, but the myocardium of the left ventricle was hypertrophied, and there was some dilatation of the ascending aorta, but no aneurysm. The lungs showed small, scattered yellowish nodules in the pleura, and except for slight congestion and edema were normal. Exploration of the bronchial tree revealed no evidence of tumor. The liver was enlarged, weighing 2,300 Gm., and on section showed a few small nodular infiltrations. The spleen was greatly enlarged, weighing 800 Gm. On section it presented a mottled appearance, caused by yellowish raised areas against a deep purple background. The pancreas on section showed several small areas of infiltration. The prostate was slightly enlarged, but no evidences of tumor could be found. On opening the duodenum, a plum-sized tumor extending from a long narrow pedicle 1 cm. above the papilla of Vater could be seen. On its surface four ulcerations, each about $\frac{1}{2}$ to

1 cm. in diameter, were noted. On section, the tumor was similar in appearance and consistency to the lymph nodes. The pedicle of the tumor was not involved. The remainder of the gastrointestinal tract was negative.

Discussion

DR. MAX-WILHELM JOHANNSEN: In retrospect, it is always easy for us as pathologists to make the correct clinical diagnosis. The outstanding findings were an easily palpable spleen, an enlarged liver, and hard palpable lymph nodes in the supraclavicular region. The symptomatology presented was not conclusive, particularly as most of the patient's complaints improved while in the ward. Hepatomegaly and splenomegaly are frequently the expression of cardiac failure. This patient had no evidence of diminution of cardiac reserve. Portal cirrhosis or occlusive lesion of the hepatic vein or portal vein thrombosis exhibits usually, in addition to the splenomegaly, some ascites. There was no mention of this in this particular case. Other infrequent entities or, still better, syndromes, such as Banti's or hemochromatosis, etc., are just mentioned because I believe the diagnosis should only be made after the more frequent and therefore more likely diagnoses have been excluded. Hodgkin's disease, or other forms of lymphoblastomas, and leukemia seem to me to cover better than anything else the findings encountered in this patient. The definite differentiation between Hodg-

kin's disease and, for instance, lymphosarcoma can only be made on histologic examination. The differentiation of an aleukemic leukemia was mentioned previously by Dr. Sagal. Tumor was present in the enlarged lymph nodes, in the duodenal polyp, spleen, liver, and pancreas. The histology of the tumor was uniform in the sections. Tumor areas of the involved organs were overrun and replaced by small round cells usually staining deep blue. There was no recognizable pattern. The bone marrow failed to reveal any findings indicative of leukemia. Carcinoma of the duodenum is unlikely, and, per se, could not explain the splenomegaly, because of the rarity of carcinomatous invasion of the spleen.

Anatomic Diagnosis

Lymphosarcoma involving:

Pleura

Lung

Liver

Pancreas

Spleen

Duodenal polyp

Mediastinal, supraclavicular, mesenteric, and periaortic lymph nodes

Hypertrophy of left ventricular myocardium.

Bilateral pleural effusion.

Acute endobronchitis.

Benign hyperplasia of prostate (mild).

What is the age at which the greatest number of deaths occur? In the United States, as constituted today, more persons die at age 71 than at any other age, except in the first year of life. In 1939—the latest year for which we have data available—there were 108,846 deaths of infants under 1 year of age and about 30,000 deaths of persons at age 71.—*Statistical Bulletin, Metropolitan Life Insurance Company*

A lawyer got into an argument with a physician over the relative merits of their respective professions.

"I don't say that all lawyers are crooks," said the doctor, "but you'll have to admit that your profession doesn't make angels of men."

"No," retorted the attorney, "you doctors certainly have the best of us there."—*Nebr. State Med. Jour.*

SEX EDUCATION FOR EVERYBODY

The American Medical Association has issued a series of booklets entitled: "Sex Education for the Adolescent," by George W. Corner and Carey Landis; "Sex Education for the Ten Year Old," by M. Marjorie Bolles; "Sex Education for the Pre-school Child," by Harold E. Jones

and Katherine Read; "Sex Education for the Woman at Menopause," by Carl G. Hartman; and "Sex Education for the Married Couple," by Emily Hartshorne Mudd.

These pamphlets are available for the public at the cost of 15 cents per single copy.

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the College and Hospital, students, and visitors. The next report will appear in the June 1 issue and will concern "The Use of Diuretics."

Treatment of Rheumatic Fever

DR. EUGENE F. DuBOIS: Fortunately, we have as our main speaker today Dr. Homer Swift of the Rockefeller Hospital, who is going to talk to us about the treatment of rheumatic fever.

DR. HOMER SWIFT: In our discussion of rheumatic fever are included the active cardiac manifestations of the disease, for consideration simply of rheumatic arthritis and the acute intoxication would hardly be worth an hour's time. We have therapeutic agents that are effective in controlling these arthritic manifestations but, if we consider the disease as a whole, it would require many hours.

Obviously, our treatment of any disease is conditioned largely by our knowledge of that malady, by our conception of its nature and etiology, and by the effects of drugs and other therapeutic measures that are at our disposal.

The therapeusis of rheumatic fever involves a great deal more than the mere treatment of the individual. With the concept of the disease most widely held today, it is also a public health problem. Unfortunately, the people most often affected are usually encountered in that class of society which is least able to care for itself either medically or economically. Numerous investigations have strikingly demonstrated among the British that it is ordinarily a disease of poverty. Probably a spot map of the cases in New York City would reveal a similar tendency and would reveal that the majority of rheumatic patients come from the poorer class of society. From such data it appears that the broader aspects of treatment lead us into the field of public health, for were it possible to limit markedly the effect of the early ravages of rheumatic fever there would probably be a marked drop in the incidence of severe heart disease in the third and fourth decades.

Rheumatic fever has various stages. We designate the earliest one as the acute stage, with severe toxic manifestations, high fever,

and exudative phenomena, such as is well illustrated by an acutely involved rheumatic joint, which is painful, swollen, red, hot, and tender, from which, under proper conditions, you can aspirate a certain amount of exudate. At this stage, if there were an accompanying carditis, one could doubtless find many polymorphonuclear cells in the most intensively involved portions of the heart. With pericarditis there is a serofibrinous effusion; with pleurisy, an exudate containing much fluid and many white blood cells. The patient at this period is usually extremely toxic. The laboratory findings will demonstrate rather striking abnormalities: There will probably be comparatively high leukocytosis, not so marked as in pneumonia, but between 10,000 and 20,000 white blood cells per cubic millimeter, and at this time the erythrocyte sedimentation rate is usually rapid.

At the other end of the active disease, when it has become chronic, these striking and easily elicited manifestations mentioned are rarely present. Fever is low grade or equivocal; leukocytosis is not marked and may not even be present. The erythrocyte sedimentation rate, while abnormal, is not nearly so rapid as in the early acute stages of the disease. In this subacute or chronic stage, according to our experience, one encounters relatively few exudative phenomena. The histopathologic abnormalities in this period are proliferative in nature. These proliferative lesions are most easily studied in subcutaneous rheumatic nodules, which clinically last for weeks to months. These lesions, moreover, comprise practically the only tissue that can be easily excised during the life of the patient, and numerous histopathologic studies have demonstrated them to be essentially proliferative and granulomatous in nature. The submiliary rheumatic nodules (so-called Aschoff bodies) in the hearts of patients who succumb to active rheumatic carditis contain similar cellular

components. As the granulomas disappear, they leave scars. In this granulomatous stage the disease may persist for months and sometimes for years. Moreover, the scars contain largely collagen, which is the tissue in which the primary injurious effect of the "rheumatic poison" exerts its chief action.

The protean picture of rheumatic fever results from varying combinations of the acute, subacute, and chronic manifestations and is conditioned to a considerable degree by the relative amount of involvement of the various organs.

In most patients the onset is characterized by acute toxic and exudative symptoms and signs. A few patients quickly pass out of this stage and go on to recovery without any further trouble. Most of them, on the other hand, recover only partially, then have one or more alternating cycles of improvement and relapses; and as time goes on the chronic manifestations become more conspicuous, consisting of low grade fever, high pulse rate, signs of progressive carditis, abnormal but low-grade increased erythrocyte sedimentation rate, and slight leukocytosis. A common feature of the disease at this late stage is an abnormal temperature and pulse response to relatively slight physical or emotional exertion. Probably most patients after recovery from a single attack could lead fairly satisfactory lives with the cardiac damage resulting from this primary attack, provided they escaped further recurrences of the rheumatic infection. The great importance of rheumatic fever is that a patient who has once suffered from the disease is liable to one or more subsequent attacks, and with each there is increasing cardiac involvement. By and large one may say that the amount of heart disease a rheumatic patient suffers later in life is roughly proportional to the number and severity of attacks of rheumatic fever he has previously experienced. Whether each one of these attacks a patient may suffer year after year, or even with intervening well periods of three to five years, is a relapse of an old chronic condition or is a new attack is a matter of opinion; and up to the present no conclusive evidence can be adduced to support either side of the argument. From both prophylactic and therapeutic points of view, it is important to remember that they occur; hence, it is necessary to consider the circumstances whence they seem to arise and to alter those circumstances in so far as such alterations are amenable to beneficial influences.

Some environmental influences, already mentioned, which may be of etiologic importance require additional consideration. These are the social status, the home surroundings, and the familial incidence of rheumatic fever; the latter has been well investigated by Dr. Wilson and others. Where these familial tendencies arise, I think, is a matter for more study, for one cannot dismiss the subject with a bare statement that either heredity or environment is the dominant factor. The picture at best is complicated, for in those families where multiple cases are demonstrable often there are also special opportunities for infectious agents, classifiable as respiratory, to be transmitted from one person to another.

At this point the possible etiologic role of hemolytic streptococci in respect to rheumatic fever should be discussed. I believe that role to be an important one. Moreover, it seems to me that we have argued ourselves into a state of defeatism concerning the etiology of rheumatic fever because of the peculiar evolution of our current knowledge of this disease. If we should consider, perfectly objectively, certain well-established relationships, perhaps we might demonstrate some factors that are subject to control.

For example, from Denmark, where both hemolytic streptococcic sore throats and rheumatic fever are officially reportable, Madson and his coworkers have reported several series of epidemics, occurring in various years, where outbreaks of streptococcic angina were followed by significant rises in rheumatic fever in the streptococcic-infected population. The peaks in the streptococcic epidemics preceded those in the rheumatic fever cases by two to four weeks.

In the British Navy, Green observed the following relationships. In training ships where young recruits were introduced in two different categories, the incidence of streptococcic sore throats was maintained at a high rate, and numerous cases of rheumatic fever occurred among the infected youths. One group of boys who were training to become technicians were admitted to the ships every three months; the others, training to become common seamen, entered the ships every week or two. This mode of admitting boys to the ships closely resembled that observed by Webster at the Rockefeller Institute and Topley and his coworkers in England to be the most favorable for maintaining a high sick rate among experimental animals subjected to certain epizootic diseases. Interrupting the constant

introduction of new susceptible subjects resulted in a drop in the epizootic diseases in the animal colonies. Likewise, limiting the admission of new classes of naval recruits to three monthly intervals was followed by a marked drop in streptococcic sore throat and a nearly complete disappearance of new cases of rheumatic fever. The relationship seemed statistically significant.

The high incidence of significant increases in so-called antistreptolysin O in the serum of rheumatic fever patients indicates that most, if not all, of these patients are suffering from hemolytic streptococcic infections.

Finally, in chemoprophylaxis, to be discussed more fully, there is highly suggestive evidence of a significant etiologic role of hemolytic streptococci. When the administration of a drug prevents the occurrence of both a specific infection and a secondary condition, possibly due to that infection, there is great probability that the primary infection and the secondary condition are causally connected. One must, of course, admit that the same drug might be prophylactically effective in two different and nonrelated diseases in the same person; but, when all of the above-mentioned phenomena are considered, one emerges with a firm conviction that the etiology of rheumatic fever is closely linked to hemolytic streptococcic infections.

In connection with this sketchy discussion of hemolytic streptococci and rheumatic fever, one naturally should try to answer the question of how these microorganisms cause this peculiar disease in certain infected people and not in others when the tissues of both groups have been invaded by hemolytic streptococci. One can best answer that on the basis of tissue reactions peculiar to the rheumatic subject and cite the protean manifestations of syphilis as an illustration of the result of differing tissue reactions. During his entire morbid life, a syphilitic individual is harboring the same strain of spirochete: first, the localized chancre; then the widespread roseola; then periods without any visible active rash, followed by successive rashes or visceral lesions ever more and more localized but increasingly focally intense until the tertiary gummatous stage is reached. Artificial reinfection at any stage will, if at all effective, induce lesions usually encountered in the patient at that stage. Obviously, the differences in the syphilids are due to the patient's peculiar partial immunity and tissue reactivity.

Leaving this hasty sketch of a rough parallel in syphilis and rheumatic fever, we must con-

sider the therapeutic indications of the latter at various stages. In the presence of the acute disease, we must try to combat the toxic manifestations. That is obvious, if we can. No single specific strain of streptococcus has been demonstrated as the cause of the disease, but many different types appear to be implicated. We have no antitoxic serums that will combat these acute manifestations. In fact, a strange phenomenon is that many antistreptococcus serums, when given to these patients, make them worse. That is an old observation that has been repeatedly reported by physicians attempting serotherapy.

In the acute stage there are usually high fever, rapid pulse rate, and exudative migratory polyarthritis. Fortunately, to combat them we have certain drugs with remarkable properties. In all of the field of therapeutics, there are few, if any, more marked effects than those induced in these acute rheumatic manifestations by suitably given doses of salicylates, neocinchophen (mentioned because of historical interest), and aminopyrine (pyramidon). The third acts more strikingly and rapidly in reducing the fever, eliminating the toxicity, and relieving the polyarthritis of rheumatic fever than any other drug I have encountered.

The side actions of these various drugs are known to you. The least dangerous, but probably the most troublesome, are those of the salicylates and are included under the general term of "cinchonism." Neocinchophen has similar side actions, with the additional possibility of hepatic damage. Aminopyrine, as you know, has an untoward effect in depressing the function of the blood-forming organs in certain patients, which eventually may lead to a serious or fatal granulopenia. Fortunately, in our experience we have seen only 1 individual with rheumatic fever where the drug had to be withdrawn because of a dangerously low white blood count. But in view of the side actions of this drug, if the patient develops a white blood count as low as 4,000 or 5,000, one naturally discontinues its use.

What are the relative advantages of each of these drugs? Salicylate is probably the safer, but the peculiar benefits from aminopyrine, in my opinion, arise from the fact that many patients with a marked acute rheumatic carditis and secondary congestive manifestations involving the gastrointestinal tract tolerate salicylates poorly; in such patients aminopyrine is the drug of choice because of its lack of unpleasant gastrointestinal irritation. Pa-

tients can take aminopyrine and digitalis together much more easily than they can take salicylates and digitalis because each of the latter induces nausea and vomiting in the higher dosage. Digitalis is indicated, I think, in patients with acute rheumatic carditis in whom heart failure with congestive manifestations has occurred. One encounters the opinion that this drug has no beneficial effect in acute rheumatic carditis, but I feel that perhaps these therapeutists have not given it with full appreciation of all of the complicating factors. Unfortunately, in these patients the electrocardiogram is a less reliable guide than in the case of simple congestive heart failure because digitalis and rheumatic carditis induce similar electrocardiographic pictures; so, in giving this drug, one must be guided by a careful study of the patient who is evincing these peculiar manifestations of acute cardiac damage.

When a patient in the acute stages of the disease has been rendered symptom-free, the antirheumatic drugs are gradually withdrawn. In checking the effect both of giving and withdrawing these drugs, a chart is most useful whereon one documents daily the various symptoms and signs and the dosage of drugs. The relationship between drug therapy, natural resistance, and symptoms will thus stand out more clearly. Too rapid withdrawal of the drugs results in a return of the symptoms and signs. Proper drug therapeutics will keep the patient symptom-free and thus permit an easier maintenance of a proper nutritional state, for a patient suffering from severe intoxication and wracking pain is difficult to nourish. Indeed, a full nutritious diet, easily digestible, is an important part of a rheumatic patient's care.

In the subacute and chronic stages of the disease, one often has to cater specially to a capricious appetite; and the weight chart is one of the important guides to the patient's condition.

Because of the frequency with which the heart is involved, one pays special attention to protecting that organ as much as possible; and the most important measures in this respect are properly enforced rest and slow restitution to normal physical activity.

In my talk in 1940, I tried to point out that if you had a pair of sore joints in your two index fingers and you cracked them together 120 times a minute, you might gain a little conception of what is happening to the heart valves. If you could reduce that effort by ten counts a minute you would save 14,000 movements a

day. If you reduce the pulse from 120 to 100, you have saved 28,000 impacts on the heart valves. Such a saving of motion not only reduces the total amount of functional valvular trauma but increases the total period of diastolic rest, which favors recovery. The antirheumatic drugs by their antitoxic, antipyretic, and antiphlogistic actions all tend to reduce the heart rate and, if for no other reason, are of distinct benefit.

There is ample evidence for the statement that these drugs will not prevent the proliferative manifestations once they start to appear, so you cannot rely entirely upon drug therapy to bring about a cure, but you must apply all other available therapeutic measures in this chronic stage of the disease, such as properly enforced rest, good food, suitable psychotherapy, and carefully regulated convalescence.

There have been two measures of chemoprophylaxis advocated: the sulfonamides and the salicylates. You may have seen the recent report of Thomas and her coworkers in Baltimore, where over a four-year period they have given sulfanilamide to patients, adolescents and adults and a few children, who have previously suffered one or more attacks of the disease without any recurrences being observed; but in the group of untreated controls there were 10 per cent of relapses. The prophylactically treated patients took small doses of sulfanilamide daily from October to June.

Drs. Coburn and Moore, in a comparable study of children here in New York, have noted a similar effect, but they observed more toxic manifestations of sulfanilamide when given over a long period. Recently, Kuttner has made similar observations in a most carefully controlled study. One cannot lay too much emphasis on that phase of this problem, for, as is known to you, any patient who is subjected to this kind of chemoprophylaxis should be most carefully observed.

Practically none of Dr. Thomas' patients had to be withdrawn from the treated group because of toxic manifestations. The average dose of sulfanilamide administered was 1.2 Gm. a day. In other studies that have been reported the dosage per day was from 2 to 3 Gm. That difference in dosage may be important, for, if the smaller amount is sufficient, it is probably a safer procedure (namely, 1.2 Gm.). The final decision concerning effective prophylactic dosage and relative danger from prolonged administration must await further observation in various places, but that there is a definite effect we must accept.

Another prophylactic measure that has been reported by Schlesinger and others in England is the administration of fairly large doses of salicylates (in the form of aspirin) to rheumatic subjects after the onset of the streptococcic sore throat. For a moment it may be well to contrast these two prophylactic technics. The usual course of events is as follows: streptococcic infection; latent period of from a few days to three weeks; rheumatic fever. The administration of sulfanilamide does not appear to prevent the rheumatic fever, if postponed until after the onset of the streptococcic infection; and incidentally, it has no beneficial effect when given to patients with active rheumatic fever. On the other hand, Schlesinger reports that aspirin when administered to rheumatic subjects immediately after the onset of the streptococcic infection and during the time of the usual latent period prevents the expected rheumatic fever. Whether this is merely a masking of clinical symptoms or a true prevention of rheumatic fever has not been determined, for the antisymptomatic effect of salicylates is well recognized, and to arrive at a definite decision the aspirin-treated patients should be studied with all available laboratory technics as well as by simple clinical methods, for laboratory methods often reveal the presence of rheumatic activity below the clinical horizon. The masking of the true picture of rheumatic fever by salicylates has probably been one of the most potent inhibitors in the studies of the true nature of this disease.

I have exceeded the time assigned me by Dr. DuBois, so in spite of many features that might have been considered, we must pass on to the more informal discussion.

Dr. DuBois: It would be interesting for the record if you would give us the usual dosage of the salicylates and aminopyrine and neocinchophen that you use.

Dr. Swift: The average dose of salicylates, for sodium salicylate—and we always give that with a little excess of sodium bicarbonate—varies from 7 to 10 Gm., divided throughout the day; that is, at the beginning one tries to saturate the patient and then to drop the dose to a point below which the patient is free of the toxic manifestations of salicylism and of the unpleasant symptoms and signs of rheumatic fever.

We found the doses of neocinchophen to be about the same. I mention neocinchophen only because at one time it enjoyed quite a vogue, but today it is little used for this condition.

Aminopyrine, for the average child, is given in a total of somewhere between 1.5 and 2 Gm. a day. For an adult you may give from 2 to 3 Gm. a day. It is important in administering aminopyrine to divide the dose so that the patient is under its influence constantly. It took us a year or two to detect this feature, being used to giving salicylate during the day and having the effect carry over through the night. We did not appreciate that aminopyrine is excreted rapidly, and one must give it from early in the morning until late at night so that the patient never escapes the influence of the drug.

Dr. DuBois: You wake the patient during the night?

Dr. Swift: No, the first dose is given when he awakes in the morning and his last dose at eight or nine o'clock at night; do not let twelve-hour intervals elapse between the night and morning dose.

Dr. DuBois: Have you used the sulfonamides?

Dr. Swift: Not prophylactically; I merely reported to you what others have done. Children have received 2 to 3 Gm. daily, which looks pretty high. The Baltimore Group report their dose as being about 1.2 Gm. per day, and with children I think it might be smaller. I do not know what eventually will be found efficient because more study is needed to settle this point. Possibly some other sulfonamide derivative will be better.

Dr. DuBois: When you are giving the so-called dangerous drugs such as neocinchophen and aminopyrine, how often do you take blood counts?

Dr. Swift: Once a week with patients in the subacute stage or chronic stages, but in the acute stages more often.

Dr. DuBois: You would not be giving these drugs in large amounts?

Dr. Swift: We might be giving the patients aminopyrine up to 2 or 3 Gm. a day.

Dr. DuBois: These patients are observed daily because they are in the hospital, but would you advise treatment with those drugs in private practice outside of the hospital?

Dr. Swift: Yes; why should not the doctor practice good medicine in the patient's home?

Dr. DuBois: Are there other questions?

Dr. C. H. Wheeler: I should like to ask Dr. Swift if there is any justification for the use of neocinchophen?

Dr. Swift: I do not think so today.

Dr. Wheeler: You do not mean to imply that it has a place in the treatment of rheu-

matic fever comparable to that of salicylate?

DR. SWIFT: I do not think so. There were some patients in the study we made during a period of two or three years who seemed to tolerate it better than salicylate; but today my drug of choice is aminopyrine. I realize that I am in the minority advocating it as a therapeutic agent; but, if you see a child or an adult with a marked acute rheumatic carditis, with nausea, vomiting, and passive congestion of the abdominal viscera, who has difficulty in taking the salicylates but responds well to aminopyrine, you would feel that the benefit outweighed the dangers. Furthermore, if there is a possibility of digitalis intoxication, you can detect it so much more easily. That to my mind is one place where aminopyrine has a great advantage over salicylates.

I know that Dr. Conner and many others like to administer salicylates by rectum to patients who cannot tolerate it by mouth. There are many patients who benefit by this change in route of administration. Don't you think that is so, Dr. Conner?

DR. LEWIS A. CONNER: I think most people tolerate adequate doses so poorly by mouth that in the hospital we have found it was simpler to make the rectal dosage the regular routine thing.

DR. SWIFT: You use starch paste as a vehicle, do you not?

DR. CONNER: No, we give it in plain watery solution, but we found that we could not use a strength greater than 10 grains to the ounce without getting some rectal irritation. The patient lies on his left side. The solution is introduced gently so that the fluid trickles in. This causes no reaction from the bowel. The liquid goes up into the sigmoid and is apparently absorbed just as effectively as a corresponding amount given by mouth.

DR. SWIFT: I can testify to that, because prior to the introduction of these other drugs, when we depended on salicylate alone, I resorted many times to that way of giving salicylates.

DR. DUBOIS: May we hear from Dr. May Wilson?

DR. MAY WILSON: I do not happen to belong to the group who believe that the streptococcus plays an important role in rheumatic fever.

I should like to ask Dr. Swift what evidence there is that chemotherapy will prevent streptococcal infections in nonrheumatic individuals? Are you familiar with any good study?

DR. SWIFT: Yes, there are many convincing studies in animals and comparable studies

in some institutional streptococcal epidemics. Individuals receiving this drug remained free from disease, while untreated controls contracted streptococcal pharyngitis and laryngitis.

DR. MCKEEN CATTELL: As I remember it, your studies and those of others have shown that sulfanilamide compounds have no value in the treatment of the disease after it has developed. I wonder how you reconcile its value as a prophylactic agent under those circumstances.

DR. SWIFT: I don't know. Something seems to occur in the tissues between the time of the streptococcal infection and the onset of rheumatic fever which alters their reactivity compared with that of a patient before the onset of the streptococcal infection. We may designate this as a peculiar type of partial immunity with hypersensitivity. Moreover, by the time the rheumatic manifestations occur, the patient has been harboring the streptococci in his tissues, especially in his cervical lymph nodes, for weeks, and it is now well known that it is difficult to eliminate streptococci from such lymphoid structures as tonsils even with intensive sulfanilamide therapy. The fact remains that this drug has no demonstrable beneficial effect in a patient with full-blown rheumatic fever.

DR. HARRY GOLD: Do you hold that aminopyrine, the salicylates, or neocinchophen have an effect on the exudative phase of the disease? You did say that the productive phase is not influenced by these drugs. Or are these drugs purely symptomatic in their effects? They relieve pain; they reduce fever; and they make the patient feel better. But if an effusion in the pleural cavity is going to develop, is it less likely to occur, or will it disappear sooner, if these drugs have been used?

DR. SWIFT: Long ago, we talked about antiphlogistics. Do you remember them? Well, to my mind, these are the most beautiful examples of antiphlogistics that one can find in the whole range of therapeutics. In patients receiving these drugs, the pain goes first. This phenomenon may result from some action on the nervous system; but, if you carefully record the subsequent state of diseased joints, you will see the swelling, the redness, the heat, the whole phenomenon designated as an inflammatory process, disappear quite promptly, and the effusion in the joint cavities is usually gone within twenty-four to forty-eight hours.

Probably if you pharmacologists and the

immunologists could combine to study these effects, something interesting would result. It looks like a true antitoxic effect, but that does not mean it is.

On the other hand, I have seen patients under full doses of the drugs, 10 or 11 Gm. of sodium salicylate a day, who developed numerous subcutaneous nodules and others who were taking 2 Gm. of aminopyrine a day and nodules likewise appeared.

It is not just an academic exercise to divide the manifestations of the disease into exudative and proliferative. Really to be guided by that concept is an important factor in therapeutics. What the drugs cannot do, you should not expect them to do. If you think, however, that they are curing all manifestations, as is the case with some physicians who give rheumatic patients these drugs and then allow them to be up and about, you fail to obtain the results you anticipate. The Aschoff body is merely a granuloma in the heart muscle; I do not think we prevent the formation of Aschoff's bodies with these drugs.

DR. GOLD: Bearing further on this point, may I ask one more question? In the case of a child with active carditis, with effusions in the pleural or pericardial sac, but without pain and with only low-grade fever, would you be inclined to use salicylates?

DR. SWIFT: Yes. You know, Dr. Boas and some of his associates have recently written a paper where they indicate that the giving of large doses of salicylates has the same effect on the pericardial effusion, perhaps a little slower, as on the effusion in the joint.

DR. CONNER: I should like to have your comments on one point: As you have said, in the fulminating cases with joint and pericardial effusion in desperately sick persons, adequate doses of salicylates and bicarbonate of soda result in dramatic improvement; sometimes, within two or three days, this tremendous effusion in the pericardium will seem to have disappeared completely. That has been my usual experience, but every once in a while, with a patient that seems to be exactly the same, the salicylate will not produce any obvious result. They will go on with pericardial effusion over a period of several weeks with apparently no response to salicylates, and I have never understood it.

DR. SWIFT: Well, Dr. Conner, I have seen on rare occasions patients with typical polyarthritis rheumatica who failed to respond satisfactorily; why those individuals do not respond, I do not know, but certainly such failures occur in polyarthritis. There are sim-

ilar failures in pericarditis. Years ago, Dr. Frank Billings advocated the use of sodium cacodylate in the treatment of rheumatic pericardial effusions. In comparing the results in our patients who were receiving salicylates, we noted that the effusions disappeared just as quickly as in Dr. Billings' cases.

DR. DuBOIS: May we hear from Dr. Murray Angevine? We are anxious to develop differences of opinion.

DR. MURRAY ANGEVINE: This is one time the pathologist has no card up his sleeve. Most of my questions have already been answered, but there are one or two I should like to ask Dr. Swift. In addition to the various chemotherapeutic methods that have been used, what precautions would you take to keep these patients from surroundings where they might be exposed to hemolytic streptococcal infections? I should also like to have you comment on the value of tonsillectomy and things of that nature in this disease. Is it worthwhile considering the matter of teeth extraction, since we occasionally see Streptococcus viridans in subacute endocarditis associated with the teeth extractions in these patients? Another question: Would you say a word or two about the value of climate? As far as the drug question goes, this discussion seems much like the ones we had when I was a medical student. The questions I have asked concern problems that are the hardest to answer and most difficult ones on which to give adequate advice to parents bringing in a child with rheumatic fever.

DR. SWIFT: If prophylaxis is closely bound up with prevention of distribution of respiratory pathogens, especially hemolytic streptococci from one person to another, we have hardly made a start compared with the measures that have been elaborated for the prevention of gastrointestinal infections, such as typhoid fever or bacillary dysentery. Admittedly, the problem is more difficult, but it will only be solved by more investigation, correct thinking, and new sanitary rules. From personal experience, however, I can testify as to the comparative efficacy of immediately boiling all utensils that come in contact with infectious material from a patient with infections of the upper part of the respiratory tract and also of isolating the patient while he harbors heavy concentrations of this infectious material. A cheap dishpan in which all dishes, napkins, etc., are immediately boiled is a sound investment. The prevention of dust-borne and clothing-borne infectious material demands more attention and new tech-

nics. Constant thought of how to diminish the danger of disseminatory streptococcic infections is important, for certainly with our current knowledge concerning the relation of these infections to rheumatic relapses one would be quite negligent of suitable prophylactic precautions should he willingly allow a rheumatic subject to come into intimate contact with a patient suffering from a hemolytic streptococcic infection. This statement is valid whether one believes that hemolytic streptococci are the direct etiologic agents of rheumatic fever or are the "detonators" that set off the explosion designated as rheumatic fever but possibly due to some other agent. How far we must travel before we institute satisfactory rules for prevention of hemolytic streptococcic infections is illustrated by those currently used in scarlet fever. The rash and peeling are still considered more important guiding criteria than the cultures of the patient's nose and throat, where as a matter of fact the rash is merely the indicator of the patient's lack of immunity to the erythrogenic toxin elaborated by streptococci growing in his nose or throat.

The question of tonsillectomy can be considered from two points of view: that of the patient and that of the disease. If diseased tonsils appear to be interfering with the welfare of the patient, they should be removed. Statistically, there is little evidence to indicate that tonsillectomy prevents a rheumatic relapse, but there is some statistical evidence indicating that in large groups less rheumatic fever occurs in children whose tonsils have been well removed than in those who retain them. Removal of tonsils does not insure freedom from future streptococcic infections, for much lymphoid tissue is left in Waldeyer's ring, and we now appreciate that streptococcic rhinitis may be as important a precursor of rheumatic fever as is tonsillitis caused by the same cocci. We have probably focused our attention too closely on the tonsils and neglected to study the diseased state of neighboring structures.

In considering dental infections, similar criteria should be applied. Diseased teeth or abscessed roots should be removed in the interest of the general health of the patient and, occasionally, one observes a cessation of rheumatic fever shortly after extraction of a diseased tooth.

DR. ANGEVINE: I did not mean in reference to rheumatic fever but to subacute endocarditis which occurs occasionally following tooth extraction. The streptococci are then

found in the blood stream. These cases are not numerous, but we have seen them.

DR. SWIFT: Yes, one occasionally observes the onset of subacute endocarditis that seems to start at the time of a tooth extraction. This is easily understood when one appreciates that there is often a temporary bacteremia of a few hours' duration shortly after a tooth extraction. Normal persons usually dispose of these temporary bacterial invaders without permanent injury, but in people with distorted cardiac valves the streptococci, usually green or indifferent, become implanted on the abnormal valves, grow into their deeper portions, and give rise to fatal endocarditis. Similar temporary bacteremia and sequelae may follow tonsillectomy or other operations on the nose and throat. Because of the bacteriostatic influence of sulfanilamide, it is probably advisable to give these rheumatic cardiac patients prophylactic doses of this drug just before, and a day after, subjecting them to any of the above-mentioned operations.

With regard to climatic treatment, if a patient can conveniently and economically be moved to a southern zone where rheumatic fever is less severe and respiratory infections are less frequent than in his usual surroundings, he would probably be helped by the move, but one should be certain that the climatic environment is favorable and the exclusion of respiratory infections probable. The latter condition often does not hold in some of our southern resorts where several trainloads of patients add their "colds" to the atmosphere each day.

In summary: The more important drugs employed in the acute stages of rheumatic fever are the salicylates and aminopyrine. Of these, the salicylates are the safest, and they are given in the form of the sodium salt in divided doses totaling from 7 to 10 Gm. per day. In patients with rheumatic fever these salts frequently cause gastrointestinal irritation, in which case aminopyrine is the drug of choice. The dose for children is between 1.5 and 2 Gm. a day; for adults, from 2 to 3 Gm. per day, always in divided doses. Because of the well-known tendency of aminopyrine to affect the granulocytes, it is important that white cell counts be done at least once a week and the drug discontinued if the count falls below 5,000.

An understanding of the different stages and manifestations of rheumatic fever and of the action of the drugs available for combating some of the symptoms should make us appreciate that although these drugs alleviate the

acute toxic symptoms and eliminate or suppress the exudative manifestations they apparently do not cure the disease. Therefore, good treatment comprises proper nutrition, prolonged rest, carefully regulated convalescence, and minute observation of the patient for relapses that may be manifest only below the clinical horizon. Because of the apparent close connection between hemolytic strepto-

coccic infections of the upper part of the respiratory tract and rheumatic fever, these patients should be specially guarded against streptococcic infections. Recent studies in which prophylactic daily doses of the sulfonamides or salicylates have been employed give promise of reducing the likelihood of relapses.

SHOULD DOCTORS TELL THE TRUTH?

Not infrequently in the practice of medicine such a problem as this arises: A woman with a suspicious lump in her breasts consults a doctor. She is accompanied by her daughter or a relative or friend who, in a private interview, requests the doctor not to tell the patient that she has cancer, if this is the diagnosis, because the patient will be profoundly shocked if she knows the truth. The doctor is urged to inform the patient that the tumor is benign, even if he believes it to be cancer.

Many years ago, the late Dr. Richard C. Cabot conducted an investigation as to the wisdom of truthfully informing patients about their disease. Using as controls patients who were purposely deceived about their condition, he concluded that from the clinical standpoint alone the patients who were told the facts seemed to do better than those who were deceived. If a policy of deception is deliberately pursued, the patient sooner or later usually learns the facts. There can be no intelligent cooperation in the treatment. The relative or friend will unconsciously lose respect for the veracity of the doctor, whether he be family physician or surgeon. If in the future the daughter has a lump in her breast and goes to the same doctor and he tells her that the growth is not malignant, the daughter will think he is deceiving her, too. How is she to know when he is telling the truth?

Thus an increasing distrust of the medical profession is bred. The very basis of scientific work is a search for truth, and doctors in the operating room, or at the bedside, or in the laboratory cannot consistently pursue the search for truth when in their communications with the patients they are purposely suppressing it. How can we expect an intelligent public to respect a profession that deliberately deceives the patient?

How can a patient reach a proper decision as to the adoption of the doctor's advice for treatment of an ailment if the fundamental facts in the case are withheld from the patient? Of course, it is unnecessary to pour brutal truths into a patient's

ear unless the patient wishes to know the truth. When the patient's relatives earnestly request that an offensive diagnosis be withheld, the doctor may respect such a request by telling the patient that this information has been imparted to the family and he prefers not to discuss the case with the patient. Then the relatives and friends can do their own lying.

Naturally the doctor should put as optimistic an outlook on any clinical situation as the facts will justify, but this is quite aside from adopting the policy of telling the patient that there is no malignant disease when the doctor believes that the patient has cancer. We owe it to the public and to ourselves to tell the patient the true situation, if the patient requests this information, and to maintain a policy that will not only be worthy of the fullest confidence of the public but at the same time will not tend to weaken our own respect for truth.

An additional incentive for telling the patient the truth is reported by Dr. Elmer Belt, of Los Angeles (*Journal of Urology*, 46:1017-1018, November, 1941). He operated upon a patient for carcinoma of the prostate. The daughter of the patient requested Dr. Belt not to tell her father that he had cancer, and the doctor complied with this request. The patient later found that he did have carcinoma of the prostate and filed a suit against Dr. Belt for \$113,500 for not telling him that he had cancer. The patient had made some financial commitments which he would not have made had he known that death was imminent. The patient said that he knew his daughter was a partner in the false presentation but he could not sue her, so he sued the doctor. The doctor employed the best legal minds to help in the problem, because this point had never before been tried in court. There were extensive preparations for the suit, but the patient died just before the suit came to trial. So this legal point is still pending.—"*Guest Editorial*" by J. Shelton Horsley, M.D., in the *Virginia M. J.*

MEDICAL LIBRARY ASSOCIATION TO MEET

The Medical Library Association will hold its forty-fourth annual meeting in New Orleans, May 7-9, 1942.

The hosts are the Rudolph Matas Medical Library of Tulane University, the Orleans Parish Medical Society Library, and the Agramonte

Memorial Library of Louisiana State University Medical Center. Hotel headquarters will be at the Jung Hotel. The program will feature tropical medicine and southern medical history. The president of the association, Miss Mary Louise Marshall, will preside.

Special Article

NEW YORK STATE'S PUBLIC MEDICAL CARE PROGRAM

LEE C. DOWLING, Albany, New York

Deputy Commissioner for Public Assistance of the State Department of Social Welfare

AMERICAN physicians are watching the development of the public medical-care program sponsored in New York exclusive of New York City by the State Department of Social Welfare and the Medical Society of the State of New York.

This public medical-care program is an unusual one, for several reasons. One reason is that, unlike most programs looking valid on paper, this one survived all the pressures against which most blueprint-programs crumble before they reach the performance stage. Further, of particular point to practitioners, this plan comprises a partnership of government and the medical profession, functioning cooperatively in the interests of the public health and welfare—without endangering medical standards or threatening the professional interests of the practitioner. A third unique factor is that this plan emphasizes the quality of medical care and actually provides administrative procedures to measure qualitative standards. Started less than two years ago, an approved local medical-care plan has already been adopted or is in course of active preparation by twenty-six counties and cities in New York State.

This program is one of the few successful large-scale attempts to utilize local public and private medical facilities for the benefit of dependent men, women, and children who need these services. That this was done without regimented socialization of private medicine, without injury to the doctor-patient relationship, without adversely affecting the economics of private practice—and with a measurable improvement in the quality, quantity, and efficiency of medical services—is a singular achievement arousing widespread interest among the medical, welfare, and other groups.

To understand intelligently the full significance this movement may hold for the American physician, it is necessary to review the situation existing two years ago when the State Department of Social Welfare was faced with the problem of creating a long-range program through which many thousands of public assistance recipients might receive medi-

cal care of a high order, through efficient and coordinated local community services and facilities, at a cost within the limited medical relief funds available. There were over one hundred local communities in the State—rural, suburban, metropolitan—that an overall program had to fit, localities in which the quality and quantity of medical services ranged from excellent to zero, districts in which facilities and resources were uncoordinated, costs out of all proportion, public and private medical agencies of widely varying effectiveness and standards—as many schemes of providing medical relief service as there were localities. The proposed plan had to consider all this, and deal with it realistically—successfully.

There were other challenges. The diverse public medical services and systems had crystallized into conventional routines and customs over long periods of time. They were becoming inviolable heritages and appendages of local government. The localities in New York State, as much as any other place in America, were sensitive to suggestions, plans, and proposals advanced by the State government. Community pride, vested interests, local autonomy, opposition to change, skepticism of the new—these and other factors were strong enough to wreck the best paper planning.

Then, of course, there was the medical practitioner, around whose skills the whole program devolved. In these days of rapid expansion of government services, the New York State doctor is no less suspicious of government medical-care proposals than his colleagues throughout the country. Besides, there was the emergency medical-care program identified with the hectic depression days when the State had to set up a tremendous relief program to care for hundreds of thousands of destitute families. So great had been the mass of human want, the emergency relief administration had had little opportunity to carefully build a substantial public medical-care service. It had to use whatever local medical services were available, was constantly reminded that

it was an emergent and temporary organization only, was sharply attacked whenever it discussed the permanent aspect of any of its work, particularly public medical care for the public-assistance case load.

So the public medical-care program was never what it might have been, what was desired by recipients, doctors, and the relief administrators. The doctor had his complaints—about numerous forms, about prior approval by the State agency for proposed medical expenditures to be made by the localities for expensive or special drugs, appliances, and services. Many of these complaints the doctor brought to his local medical society. The local medical society carried them to the New York State Medical Society. The State group brought them to the emergency relief administrators. The latter did what they could, but with overnight changes in federal relief programs, and reimbursements and everything else in a state of flux because the public had been led to believe that large-scale want was to disappear soon, the State relief administrators were not able to do all that had to be done to correct flaws in the public medical-care program.

And so this conditioned the attitude of the medical profession toward medical welfare programs. The pressures for health insurance and various other schemes did not help to alleviate the situation. The State Medical Society was adamant in its insistence on maintaining policies which the Society felt were essential to the best type of medical care.

This, in substance, was the situation that faced the State Department of Social Welfare when it assumed responsibility for the home relief population and the associated public-assistance medical-care program upon the termination of the State Temporary Emergency Relief Administration. It set for itself the goal of extending those medical services to recipients of home relief, old-age assistance, blind assistance, dependent-children aid, and to nonrelief persons who could not provide themselves with medical care. However, the Department knew that existing local medical facilities and services had to be so reorganized and coordinated as to assure improvement in the quality and quantity and efficiency of local medical services, or it would be building on an uneven and false foundation.

The Department decided to hold fast to two things: (1) its primary objective of providing adequate high-standard medical care to the public-assistance case load at costs within its limited medical funds, and (2) its

realistic concept of the multitudinous difficulties presented by community mores, wide range of public medical standards and facilities in the 105 districts, and the attitude of the medical profession toward government's bearing social gifts, particularly medical-relief schemes.

The Department invited representatives of the State Medical Society's Subcommittee on Medical Relief and the New York State Association of Public Welfare Officials to discuss a proposed public medical-care program. It was not long before several things became quite clear: the doctors and the welfare commissioners did not talk the same language, except when they expressed a healthy skepticism about State government proposals. The medical profession questioned the validity of welfare commissioners—the great majority of whom are laymen—directing medical-care programs. Under the law, however, the welfare commissioner is legally responsible to his community and to the State for the entire conduct of his department, and he can neither delegate nor share his responsibility. The doctors' attitude represented a threat to the powers of the local welfare commissioners. The latter saw no reason for the medical profession to question what had been going on for decades, even centuries, in some communities. When these factors were not supplying the fuel for discussion, the State regulation for its specific approval for certain local medical expenditures and a host of other things that both doctors and welfare commissioners remembered with great clarity and completeness, stimulated lively debates. On such issues, both doctors and welfare commissioners joined, only to separate again when the question of laymen directing medical care bobbed up. Finally, the whole thing became bogged in interminable debates about doctors' fees. It appeared that it was impossible to discuss a program even academically.

But the committee* refused to give up. State Social Welfare Commissioner Adie and his staff were determined that the public-assistance population was going to get good medical care and that local medical-care programs must meet certain reasonable standards of medical service, efficiency, and utilization of community medical agencies. There was at least one spot of common ground upon which all the groups could meet—good medical care for human beings in need of that care and without the means of providing it for

* The author of this paper was chairman of the committee.

themselves. Every man in the conference room was dedicated to that principle, professionally, officially, or personally.

Starting on that base, the subsequent discussions were rigidly confined to principles, to broad general concepts. Fee schedules, procedures, customs, everything else, was excluded. More light and less heat came into the discussions. Finally, a statement of principles was drawn up, as follows:

The medical profession should participate in all medical phases of the proposed program; all physicians and local medical societies should be encouraged to participate in the planning and operation of the local medical-relief program; complete decentralization of control in medical matters (eliminating State agency's specific approval of certain medical expenditures); free choice of doctors; use of salaried medical practice in the program where so chosen by the local community; use of clinics; inclusion of nonrelief families in the public medical-care program.

In general, all groups agreed to these principles. But the medical profession did not approve of the permissive "contract" practice or the use of clinics without rigid restrictions. Nor does it approve of these factors today, even though it endorses the new public medical-care program now in successful operation. But, to have opposed these two principles, to the point of wrecking the whole medical program, would have been alien to the best interests of tens of thousands of people in real need of medical care. Then again, the proposed medical-care program permitted several methods of providing physician's services: fee basis, either giving the patient free choice of physician or limiting the choice to a selected panel; use of public or private clinics; and salaried staff physicians to treat patients in their offices and in patients' homes, with specialists' services on a fee-for-service basis. These were methods in common use in New York communities for decades. A program that would have restricted physician's services to the fee basis would have foredoomed the program to failure in scores of communities which would not have accepted such dictation from either the State Department of Social Welfare or the medical profession. Consequently, despite its historic and continuing opposition to "contract" practice, the Medical Society of the State of New York could not assume the responsibility of taking an adamant stand which would have stopped a meritorious state-wide effort to provide higher standards of medical care to a

great number of citizens; nor could it realistically place itself in a position of imposing patterns of public services upon communities which have a democratic right to select their own modes of government and to determine their own levels of public service, however short those levels may be of the objectives of the medical profession.

The State Medical Society realized that the local community had a free choice in selecting the method of securing physician's services under the proposed program and the medical profession had an educational responsibility to see that the community chose the proper method. The State Department of Social Welfare refused even to entertain the notion of mandating the communities by forcing them to accept the fee basis, for it was contrary to democratic processes of government. The Department said its experience did not indicate the need for such a measure, and it could not do so under the Social Welfare Law. Further, it pointed out that this was a plan adapted to the locality and it was the medical profession's responsibility to convince the communities that what the medical society advocated was in fact the best method. Since the State and local medical societies were completely free to promote and encourage the fee basis, the basic policies of the proposed public medical-care program were approved by the State Society.

The same elements were involved in the principle of use of clinics, to which the State Society objected. Clinics were exploited to avoid payment of fees for services in some communities—many communities, the Society charged. Clinics should be used when medically desirable, but when exploited they are unnecessarily burdened, cutting down the time available for attention to each case. The patient is deprived of the right to be attended by his own physician. The hospital outpatient department should be used as a diagnostic center and treatment auxiliary by the private physicians and not as a catch-all for every sort of case. Evidence of these points was presented in the discussions, in which the State Medical Society explained that it could not endorse the principle of the use of clinics without restrictions which would safeguard the general practitioner from the abuses and exploitation that exist.

The Social Welfare Department understood the position the medical society had to take in the matter. The Department explained that its proposed plan would supplement and not duplicate or supplant existing facilities; that the plan was not, and could not be, a

panacea for all the weaknesses, flaws, and defects of public medical services or the longstanding shortcomings of communities' concepts of medical standards and goals; that it could not dictate drastic and radical changes in the setup of local medical agencies' services, either legally or socially; nor could it ignore the existence of medical facilities and resources in the communities, sorely limited as they are, or fail to utilize such agencies in a program designed to bring to bear all the adequate local medical services upon the burden of sickness in the community.

Such clinic services and usages of clinics as *infringe* upon and exploit the local medical profession, are matters for arbitration between local officials, the management of the clinics and the local professional groups, and are not subject to State interference, the Department contended. It was clear, the Department said, that its primary objective must be the use of existing clinics to the fullest, reasonable extent—especially where clinics are an integral part of the local community's medical services or can be properly made so. Here again, rigid restrictions, if it were practical to impose them, would have alienated a large number of communities and kept the proposed public medical-care plan in the paper stage, the Department maintained.

For the general welfare of the community, the State Medical Society went along with over-all endorsement of the basic policies of the program, but opposed the unrestricted use of clinics. The Society could not expect one State agency, with supervisory responsibility for only a fraction of the expenditures for public medical care, to try to end practices over which it has no control and which had been established during a period of decades in fields of local public service. But the Society had hoped that the Department might enforce certain limitations on the use of clinics under its public medical-care program by withholding State reimbursement where such clinics were misused. However, since the Department and the local welfare commissioners would not go along with such restrictions and the Society recognized that it and the local medical societies had a certain responsibility of their own to educate communities in this matter, the Society could not place itself in the position of blocking the proposed medical-care program on this issue, for the program provided many advantages greatly to be desired.

So, on the basis of this statement of principles, a set of basic policies was designed to

carry out the objectives of the proposed public medical-care program (see Appendix for the statement of basic policies).

When the program was finally formulated, there had been so much frank, honest, and sincere discussion between physicians and welfare commissioners, that they began to talk the same language and held to the same point—provision of adequate medical services to the public-assistance population. For the first time, perhaps, physicians began to understand the problems, factors, and conditions which fashion the welfare commissioner's considerations and judgment, and vice versa. The trust and confidence that began to develop between the two groups, right down the line from the committee members to the whole rank and file of doctors and welfare officials, were evident in the good-natured stories they told about themselves, their own errors and shortcomings. This kind of relationship grew as conferences and meetings were held periodically to evaluate the progress of the medical program as it was adopted by one locality after another following its initial installation in the summer of 1939.

The New York State Medical Society's Subcommittee on Medical Relief worked painstakingly with the Department in guiding the introduction and development of the plans. There were some early difficulties, minor and major, but once plans were introduced into a few communities and good results obtained, they moved along fast. After two years of experience, study of the results, and consideration of the problems stemming from its operation, the Department and the Society pronounce the program a success, are enthusiastic about its future, believe they have solved the riddle of organizing a good local public medical-care program which has within it the elements of a pattern of high-grade public medical care administered through principles and practices that are generally acceptable to the medical profession, and can be adapted by almost any community in America with benefit to the patient, the doctor, and the community.

It is no more perfect than any set of principles can be when translated from paper to practice, when carried out by thousands of persons, and operated in all kinds of communities, against widely varying backgrounds of medical-service conventions and customs. It does not, cannot, eliminate all of the actions of doctors, commissioners, and communities which are not for the best interests of patients or a good medical-care program, but it does discourage many of these actions, does

provide workable machinery to eliminate more of them. It does not eradicate overnight the ignorance of medical-care problems or the injurious monopolies of medical practice or the evils of wholesale clinic treatment or the lack of adequate medical case recording—all of which have become hardened arteries of a system long inured to such practices. Nor has it solved the vital factor of setting fees that please both the doctors and the taxpayers, a problem upon which many medical-care proposals founder before they even get started. It has not as yet educated the minorities in the public welfare field and in the medical profession to a point where they learn to get the facts and consider the whole problem before making noisy complaints and charges. But the program has made such substantial contributions toward alleviating these age-old problems that it has survived all of the dangers they represent to every public medical program. And that is why American physicians are becoming keenly interested in New York's program.

Analysis of two years' experience with the program shows the following: it develops coordinated and efficient use of public and private medical agencies in the community and eliminates waste and duplication; by making it necessary for the local government to choose the most suitable type of medical program and work out all the details, it focuses community attention upon medical needs and services and gives the local medical profession an opportunity to be heard in the council halls of the community; it places the medical operations of the plan in the hands of a medical man and thus places the medical profession in a key position to influence a wider and better understanding of medical objectives, standards, and services; it establishes fiscal and individual medical record-keeping, where such civic and scientific data were inadequate or absent altogether; it reduces the cost of the average medical case or makes available, through elimination of duplicatory and wasteful operations, funds which can be used for needed, additional, medical services; it has given New York State more medical directors or consultants administering medical relief-care programs than exist in all of the rest of the nation—and it does improve the quality and quantity of medical care.

The one recurrent problem, in minor or major degree, in the installation and operation of a plan, is fees. The State Medical Society committee would not approve a fee schedule at the preliminary discussions of the

medical plan, has not approved such a schedule to date, and does not propose to approve one in the future. Its position is that fees vary widely in the more than one hundred communities of New York State (exclusive of New York City, which has its own medical program), and to approve any one schedule of fees might penalize physicians in scores of communities by fixing fees at standards below what they are now receiving, and might likewise impose higher taxpayers' costs upon scores of communities in which the local fees would fall below the requirements of a fixed schedule. The mere approval of any specific table of physicians' payments would place the committee and the Society in the position of advocating, in many communities, higher relative fees than long-established conventions and customs have dictated, and of exposing the local practitioners to invidious comparison with the doctors in hospitals and clinics who donate their services without monetary compensation. Such a position would endanger the local medical profession's relations with the community, would engender dissatisfaction among the hospital and clinic men, and would reflect generally upon the local and State medical societies and the whole profession.

Other factors were considered: the great distances some doctors had to travel to reach patients in rural and sparsely settled areas, in comparison with the doctors in the metropolitan areas; the amount and costs of medicines dispensed on a visit; the obvious fact that no state-wide fee policy could possibly work without adjustments so numerous it would be impractical to devise one that could reconcile all the factors involved.

The Social Welfare Department's position was this: under the law, it is responsible for fixing a schedule of maximum reimbursable charges for services and supplies beyond which the State cannot reimburse the localities, and it is limited by the funds appropriated by the State. However, the local communities, in cooperation with the local medical societies, can fix their own fees, and make any adjustments necessary to secure maximum reimbursement. In other words, the local communities can determine their own rates of payment, just as they determine the kind of medical program they desire. Then again, the locality can pay its physician whatever it wishes, if it is willing to forego State participation on the amount above the reimbursable limit.

Tremendous savings have been made in

hospital case costs. One county reported saving \$16,700 the first year it used the plan; another county was able to reduce its hospital stay of patients 50 per cent. The sponsors are not prepared to say that their program will prove less costly than others. It may, in comparison with some plans; it may be more costly than other programs. Costs depend upon the varying factors of medical services and standards, facilities and resources available, degree of medical and fiscal control, and other factors. But the New York plan so provides for efficient use of existing medical facilities, medical and financial controls, and recording, that it does eliminate waste and duplication and does, in this area, save funds.

Two great features of the plan are stressed by its sponsors. One is the emphasis placed on the quality of care given. The emphasis is not merely confined to the written statement of the objectives of the plan. It is part and parcel of the administrative procedures, and it is an important, continuing assignment delegated to the Chief Medical Officer of the State Department and his staff. Quality of medical care is attained in several ways.

The local welfare commissioner is impressed with the need for high standards of medical care, is given illustrations of the results of inadequate, low-grade, medical services, is shown the high cost of ineffective medical procedures. His community pride is appealed to. It is made clear to him the useful role and great responsibility that are his in the medical plan. He is encouraged to use his local medical society committee to advise him about the type of plan to select and to recommend to him the best medical men in the community for the medical director's post. He is urged to realize the importance of selecting for medical director a man who has standing with the society, the local medical profession, and the community, and the all-important responsibility of selecting a panel of physicians upon the recommendation of the medical society, if such a type of program is chosen. Selection of personnel is preliminary and basic to assurance of high-grade medical care.

Local medical societies are encouraged by the State Medical Society and the Department to work closely with the local commissioner when the plan is being considered for adoption, to see local government officials and to interpret the need for the best possible kind of care, to appear before city councils and local boards of supervisors at public hearings and state and define the local medical profession's recommendations.

When a plan is adopted by a community, the Department works closely with the local welfare department and the medical director to see that it gets off to a sound start, to give whatever guidance is requested, to stay with the plan until it stands on its own, to assist in straightening out any early difficulties that may arise administratively or in the relations between the local welfare department and the local medical society. (The State Medical Society has had to be called in on occasion and, through its patient efforts, difficult differences were straightened out.)

The Chief Medical Officer then comes into the working plan and seeks to test the quality of medical care as well as the quantity, efficiency, and economy with which services are given. Testing the quality of medical care, the sponsors readily admit, is less than an exact science, but there are several sound approaches to the task and these are used. Medical case records are consulted, diagnoses ascertained, kinds and number of treatments and care given are considered, follow-up treatments are evaluated. Cases and treatments are discussed with the medical director of the program, with the panel physicians who treated the cases, with the local medical society's medical relief committee members, with hospital staff members, and others. A complete record of a case is assembled, studied, analyzed, the patient seen if necessary. Thus, to the extent possible, the standard of medical care is evaluated, and this process—part of administrative procedure and regularly reported upon—focuses the attention of those engaged in the work upon quality as well as quantity and efficiency of services.

The second great feature of the medical plan, the sponsors feel, is its educational value, its tendency to promote public interest in health, medicine, and the role of the physician in the community. Placing responsibility upon the local community for selection of the type of medical-care program it is to provide brings the issue to public attention through the necessity for the local government officials to vote upon the question. The whole matter of public medical services is thus brought forward and more often than not reviewed in public meetings, discussions, and in the press. The local medical profession, like other segments of the population, has an opportunity to express its views, to interpret its objectives and objections, to press its recommendations, and to expose fallacious proposals.

More than that, allied and related health

services are likewise publicly reviewed and discussed; public welfare officials, public health officials, private medical agency executives, and other elements of the community participate in the discussion. Since the plan calls for encouragement of the appointment of local medical society committees to advise the welfare commissioner and his medical director, and makes the appointment of a medical director or medical consultant mandatory, the medical profession is given a real part in the program, an official as well as a professional interest, and thus places the profession in an advantageous position.

In addition, bringing together all of the public and private medical interests of the community engenders healthy exchange of viewpoints, promotes understanding of individual responsibilities, functions, and objectives, tends to promote coordination and cooperation, and helps to eradicate much of the misunderstanding and fears that the different groups may have held for each other. To have attended one of the early stormy meetings of the groups that met with the State Department in 1937-1938 and then to attend such cooperative meetings today would lead the observer to believe that some miracle must have occurred or the confreres must have been replaced by others. It was neither a miracle nor a change in the personnel of the committees. It was the achievement of adults who were able to get together on the fundamental principle that human beings in need of medical services should receive good medical care, and they went on from there to modify their special interests to the greater interests of men, women, and children in need of the services they had the power and skill to give.

Such modifications as were made by the welfare commissioners and the medical men were not sacrifice of principles but reasonable subordination of special interests to the greater good and greater claims of the public interest, a truly democratic performance that left the medical profession free to continue its fight for such standards and conventions as it feels must some day be accepted by a better-informed public. The welfare officials maintained their right to administer their programs, and the medical profession gained the right to guide the medical aspects of the programs.

Since the operation of the plan thus far has shown a tendency to increase the fee-basis method, the use of clinics and the use of salaried-practice methods have brought fewer problems than had been expected; and in many instances the number and kind of abuses

frequently charged to these factors consequently declined. However, in the case of one community, it dropped the fee-basis plan and switched over to the salary method.

In instances where the local communities set fees for welfare patients far below the level of fees for private patients, the Department's position is that this is a local decision and it is up to the local medical profession to get the community to understand the value of the physician's services. The Department points out, too, that prior to the founding of medical relief programs in the early depression days, the medical profession bore the full brunt of providing its services to destitute families who could not pay—an unjust burden upon a small fraction of the population. It feels that all of the local communities have come a long way since then, and now the medical profession is being paid for such services, even though, in some communities, the local practitioners feel they are not receiving as much as they should.

From its long experience in dealing with localities and local government, the Department believes in doing everything possible to help spread a better understanding of medical and social needs by practical demonstrations; and that progress and development of medical and social programs cannot be achieved by imposing State government philosophy or regulations, but rather by a patient, cooperative, relationship which will in time become fruitful in encouraging the community to advance through increasing levels of social conscience and thinking.

The sponsors point out that as yet no community has set injuriously low fees, viewed against the background of the community's standards. In the few instances where the local medical profession was belligerent in its opposition to the local fee schedules or in its efforts to have such fees increased, it was possible for the Department and the State Medical Society to help bring about amicable settlements.

The advantages and results of the local medical-care plans have been so numerous that even if the number of problems and the minority of critics were much larger than they are, they would still be outstanding examples of successful partnership of government and private medicine in the important task of providing needed medical services to persons who have no means of providing such care for themselves.

The enthusiasm of the sponsors, and of the new medical directors, the welfare commis-

sioners, and the local medical society committee members, in getting their communities to adopt an effective local medical-care plan augurs well for the success of their new adventure, which holds great promise for the public good. The great human desire to build, to benefit, to do good, is the powerful drive behind this movement, the force that gives it its momentum and keeps it rolling.

This local medical-care program is rapidly changing the whole pattern of public medical care in the social welfare field in the State,

supplanting archaic practices and systems, coordinating local public and private medical facilities into a coherent community program, placing a medical man in charge of the medical aspects of the program, setting up diagnostic and fiscal records, building a whole new approach to public medical care, and establishing new forms of medical service which may influence government-physician relationships and public health movements for decades to come.

APPENDIX

New York State Department of Social Welfare Medical Care Program for Locally Administered Medical Care Plans

Legal Basis

The medical-care plan, both in function and in structure, is governed by two basic sections of the State Social Welfare Law:

(a) "Section 184. *Responsibility for providing medical care.*—The public welfare district shall be responsible for providing necessary medical care for all persons under its care, and for such person(s), otherwise able to maintain themselves, who are unable to secure necessary medical care. The determination as to medical care necessary for any person shall be made with the advice of a physician."

(b) "Section 185. *Place of care.*—Medical care may be given in dispensaries, hospitals, the person's home, or other suitable place."

The essential requirements, scope, and functions of the approved local medical-care plan, together with an account of the installation process, are summarized below.

Requirements for Approval of Plan

The State Department of Social Welfare has established the following requirements as the minimum essential to its approval of a local medical-care plan:

1. *Local medical direction and administration.*—The commissioner of public welfare, with authority and responsibility for providing medical care, shall delegate the direction of the medical aspects of the plan to a licensed physician of his choice. He must establish a central medical unit, properly staffed and equipped to handle or refer all requests, (a) from or in behalf of patients in need of medical care at public expense, and (b) from the physicians, dentists, nurses, pharmacists, clinic and hospital administrators who are authorized to supply such care.

2. *Definition of scope of medical-care plan.*—Written statements shall be prepared to define clearly the policies, procedures, items, and terms (including payments) which govern the respective functions of each participant in the operation of the plan. These itemized statements are to be designed, by mutual agreement, for the use of physicians, dentists, nurses, pharmacists, hospitals, etc. (vendors or providers of medical services or supplies), as well as participating

members of the welfare department staff (medical, social service, and accounting divisions).

3. *Medical and social coordination.*—The plan must provide for: (a) the use of physicians to determine the medical needs of any person applying for medical care; (b) the use of social workers to determine financial eligibility of such person for care at public expense; (c) informing social workers of the medical and social needs of the applicant, and for joint planning between medical and social workers where there is an interdependence between the treatment and social factors in the case; and (d) the application, as rapidly as possible, of one system of providing medical care for all persons receiving public assistance, regardless of category of assistance.

4. *Medical and fiscal record keeping.*—The plan shall provide for the establishment and maintenance of: (a) medical-care records showing the diagnosis and treatment for individual patients; (b) cost records according to type of medical or other professional services or supplies furnished; and (c) an accounting system conforming to the regulations of the State Department of Social Welfare.

5. *Integration with community medical and health resources.*—An accurate and up-to-date inventory shall be established and maintained of all medical and health facilities and services available in the community under federal, State, local, public, or private auspices, so that full and proper use may be made of each in a well-rounded medical-care plan.

Scope of Plan

The scope of an approved medical-care plan may vary as to items of service and forms or manner of distribution of such services.

A. *Items of medical care.*—The plan may provide for all forms of medical care including—regardless of the extent of State participation—many or all of the following:

- Acute illness, home or office
- Ambulance service
- Boarding homes for invalids
- Chronic illness, home, office, etc.
- Clinic care, by referral
- Consultant services

Dental care, including
 Prophylaxis
 Treatment
 Fillings
 Extractions
 Dental surgery
 Dentures
 Drugs, sera, etc.
 Eye examinations
 Eyeglasses and glass eyes
 Fractures
 Hospital care
 Laboratory services
 Major surgery, home or hospital
 Medical services in hospital
 Minor surgery
 Nursing care, including
 Visiting nurse, per visit
 Registered nurse, per day
 Practical nurse, per day
 Home medical aides
 Nursing home care
 Obstetrics; home or hospital
 Physiotherapy
 Pneumonia treatment
 Preventive services, by referral
 Prosthetic or surgical appliances
 Radium treatment
 Sickroom supplies
 Specialist services
 Tuberculosis treatment, home
 Venereal disease treatment
 X-ray diagnosis
 X-ray treatment

It should be recognized that while all of these items of medical care can come within the scope of Section 184 of the Social Welfare Law as a responsibility of the local welfare district, State reimbursement for some expenditures is not available because of specific legal restrictions or exclusions.

B. Types of medical-care plans.—The items of medical care listed above may be provided through a number of patterns. Because of the large number of local variables, each new plan adopted may differ from the others. The following are representative types of plans and indicate certain patterns chosen by particular communities to fit local circumstances and customs:

1. *Free choice, fee-for-service, medical-care plan in a rural county.*—Hospital care provided in county hospital supported jointly by the County and the State Health Department. Medical and surgical services in this hospital given by staff physicians.

2. *Salaried, part-time, restricted panel, medical-care plan in a metropolitan and suburban county (operated on a district basis).*—Hospital care: (1) acute cases, in private and teaching hospitals; (2) chronic and subacute cases, in infirmary attached to County Home. Hospital clinics used for diagnostic and specialist services only. Hospital or clinic staff physicians provide hospital or clinic care.

3. *Combination of salaried, ambulatory care, and free choice, fee-for-domiciliary service, in a medical-care plan in a small city.* Salaried physician in welfare department provides care for ambulatory patients and follows up patients admitted to local hospital.

4. *Salaried city physician and department surgeon providing home, clinic and hospital services in a city, with specialists, emergencies, and hospital services for non-settled cases paid on a fee-for-service basis.*—City physician supervises whole program and in addition makes home visits, provides obstetrical care, and conducts a clinic for ambulatory patients. With exception noted above, department surgeon performs all operations on a referral from city physician.

5. *Free choice, fee-for-service, medical-care plan in a suburban county.*—Home, office, and hospital care provided with free choice by patient of private physician, surgeon, or hospital. Medical consultant supported by strong medical advisory committee to control care and enforce maximum annual payments per patient and per physician.

Installation of Plan

1. *Medical survey.*—A study is made of the present medical policies and procedures of the local welfare district. A list is established of all available medical resources, including those maintained by federal, State, and local public agencies, such as the Public Health Service, State Departments of Health, Education, and Mental Hygiene. To this list are added the medical resources maintained by voluntary agencies and available to recipients of public assistance. An analysis is then made of the medical survey and available medical resources to determine what new or revised policies, procedures, and fees are indicated.

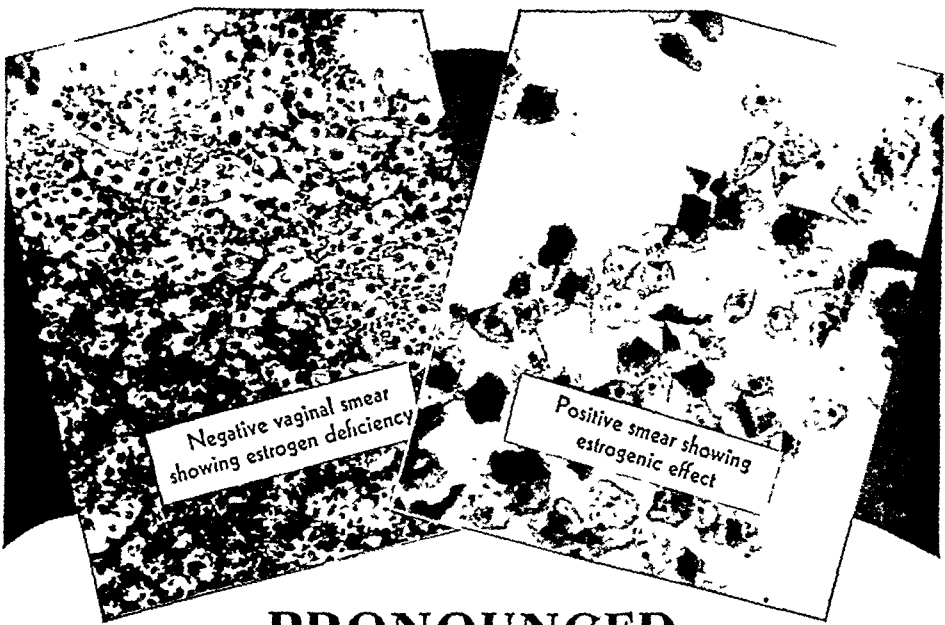

2. In the order acceptable to the local officials, the following steps are taken: (a) sections of the medical plan are written; (b) forms and record cards are worked out; (c) fees for individual medical items are established; (d) advisory committees of participating professional groups review the drafts of sections pertaining to their profession.

3. When the draft of the local plan is completed and acceptable to local welfare officials and participating professional groups, it is submitted to the State Department of Social Welfare for review and approval for installation.

4. The local commissioner of public welfare mimeographs or prints his medical plan in the form of a medical manual and distributes it to the participating professions and vendors of supplies. Copies are filed with the State Department of Social Welfare and the State Department of Audit and Control.

5. The staff, including the Medical Director (who may have been appointed during the period of writing the plan or prior to that), is assigned to the central medical unit of the local welfare department. Beginning on a specified date, medical care is authorized according to the policies, procedures, and fees of the locally established plan. According to the size and needs of the local community, the medical unit staff includes any or all of the following types of personnel: (a) physician, who is the medical director or consultant (required); (b) medical social worker; (c) medical worker, who may be either a nurse or a social worker; (d) pharmacist; (e) clerical and stenographic staff; (f) accounting staff.

6. Continuing relationship with professional groups is maintained through the medical com-

mittees advisory to the commissioner of public welfare and the medical director or consultant. These committees have no administrative responsibility and serve in an advisory capacity only.

7. The services of the State Department of Social Welfare's medical staff are available to the local commissioner of public welfare during all the processes of writing and installing a local medical plan.

PHYSICIANS SAY MALNUTRITION IS WIDESPREAD IN THIS COUNTRY

"The evidence at our disposal warrants the conclusion that dietary inadequacies and malnutrition of varying degrees are of frequent occurrence in the United States and that the nutritional status of an appreciable part of the population can be distinctly improved," Norman Jolliffe, M.D., New York; James S. McLester, M.D., Birmingham, Ala., and H. C. Sherman, Ph.D., Sc.D., New York, declare in summarizing a paper on "The Prevalence of Malnutrition," published in *The Journal of the American Medical Association* for March 21. "If optimal nutrition is sought, not mere adequacy, widespread improvement is possible," they add.

In the introduction to their paper they explain that "Recent estimates of the prevalence of malnutrition in the United States have varied so greatly that the Food and Nutrition Board of the National Research Council has assigned to us, as a subcommittee, the task of evaluating existing evidence on this question. Among the reasons for the widely varying estimates is the lack of criteria for the diagnosis of malnutrition. It is therefore necessary before discussion of the evidence that terms be defined.

"Nutritional failure' exists as soon as adequate amounts of an essential nutritional factor or factors fail to reach the 'milieu interne' [desired state].

"Dietary inadequacy' means the failure to ingest an essential nutritional factor or factors in amounts sufficient to meet the existing requirement of the body.

"Nutritional inadequacy' means not only the failure to ingest, i.e., dietary inadequacy, but failure to absorb, to retain, and to utilize an essential nutritional factor or factors in amounts sufficient to meet the existing requirements of the body.

"Malnutrition' is a bodily condition, detectable by any method of examination, caused by a nutritional inadequacy."

In their summary they say that "Malnutrition is accompanied by manifold signs and symptoms, diverse in nature, and to the casual observer their origin and significance is not always apparent.

"Some types of malnutrition are strikingly obvious to every one, some are apparent only to the physician who looks for them, and some are vague and elusive even to the careful observer using the most accurate specialized technics. If the first group alone is counted, the prevalence of malnutrition will be recorded as low, almost negligible. If the second group is counted, it will be recorded as high. If the third group is included, then the rate will be sufficiently high to occasion genuine concern."

THE DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal of the American Medical Association will be presented for the fifth time at the opening general meeting during the annual session of the association in Atlantic City, June 9. This medal was awarded, for the first time, in 1938 to Dr. Rudolph Matas of New Orleans, in 1939 to Dr. James B. Herrick of Chicago, in 1940 to Dr. Chevalier Jackson of Philadelphia, and last year to Dr. James Ewing of New York. This award has come to be recognized as one of the most distinguished honors conferred by the American Medical Association. The method for selecting the recipient is specifically defined in the by-laws of the association. Any Fellow of the association may submit nominations, which should be sent, together with a record of the scientific services of the nominees, to the chairman of the Committee on Distinguished Service Award, Dr. A. A. Walker, 2250

Highland Avenue, Birmingham, Ala., or to the secretary of the association at 535 North Dearborn Street, Chicago. Of all nominations received by the committee, five are submitted to the board of trustees of the association, from which the board selects three to be submitted to the house of delegates at its first meeting at the time of the annual session. Immediately on submission of the nominations by the board of trustees, the house of delegates, by official vote, selects the recipient of the honor, to whom the Distinguished Service Medal is presented at the opening general meeting on the evening of the following day. An extended list of distinguished physicians nominated for this award will enable the committee, the board of trustees, and the house of delegates, all of whom participate in the selection, to choose for 1942 a recipient of distinction.

—J.A.M.A.

PHYSIOLOGIC ANTISEPSIS WITH **ARGYROL**

NO CILIARY INJURY

DECONGESTION WITHOUT VASOCONSTRICTION

DETERGENT AND DEMULCENT

NO PULMONARY COMPLICATIONS

NO SYSTEMIC TOXICITY

Safe and Effective Mucous Membrane Therapy

The ability to kill micro-organisms is but one of many factors which determine the clinical efficacy of a mucous membrane antiseptic.

It is because ARGYROL impedes bacterial life without injuring the tissues; because it aids and does not impede those natural defensive processes which the tissues employ to throw off infection, and because it is non-noxious to the organism as a whole, that ARGYROL is truly a "physiologic mucous membrane antiseptic."

ARGYROL effects a decongestion through circulatory stimulation and without resorting to powerful artificial vasoconstriction. Because of its unique physical properties it is detergent,

demulcent, and inflammation-dispelling. But it is non-injurious to the cilia—whose vital role in overcoming upper respiratory infections has been repeatedly pointed out. ARGYROL remains equally bland and non-irritating to the tissues in all concentrations from 1% to 50%, and it is free from the dangers of systemic toxicity and pulmonary complications.

ARGYROL has a superior clinical record to all other mild silver proteins and it is chemically and physically different—in colloidal dispersion, in Brownian movement, in pH and p_{ag} and in chemical reactions. Insist on the Original ARGYROL Package.

A. C. BARNES COMPANY, NEW BRUNSWICK, N. J.

ANTISEPTIC EFFICIENCY PLUS

1. SOOTHING AND INFLAMMATION-DISPELLING PROPERTIES
2. NO CILIARY INJURY—NO TISSUE IRRITATION
3. NO SYSTEMIC TOXICITY
4. NO PULMONARY COMPLICATIONS
5. DECONGESTION WITHOUT VASOCONSTRICTION

SPECIFY THE ORIGINAL ARGYROL PACKAGE

Medical Preparedness

Concerned over possible war shortage of drugs and medical appliances, The New York Academy of Medicine recently appointed a Subcommittee to study this subject. The report which follows

was approved on March 9, 1942, by the Committee on Public Health Relations of The New York Academy of Medicine. Copies of this report have gone to the authorities in Washington.

War Shortage of Drugs and Medical Appliances

Report of a Subcommittee of the Committee on Public Health Relations of The New York Academy of Medicine

BECAUSE of the war, many drugs and materials used by the medical profession are becoming scarce, or may be unobtainable. This Subcommittee was appointed to ascertain the nature of the shortages, their causes, and their remedies where possible. It has received helpful information from representatives of leading drug manufacturers and distributors, and from several divisions of the government.

Among the several reasons why drugs should be scarce are the following:

1. The supply from many foreign countries is drastically curtailed or completely shut off, either because there is little or no production in the several countries, or because shipping facilities have been unavailable. Of such scarce foreign-produced drugs, belladonna and colchicum are striking examples. In regard to shipping, the Health Supply Section of the War Production Board informs us that it has been granted priorities for drug shipments whenever shipping facilities have become available.

2. Certain basic chemical drug substances are used extensively in the manufacture of war equipment, such as alcohol, phenol, glycerin, nitric acid and nitrates, magnesium, mercury, potassium, and zinc.

Alcohol, for example, is required in the manufacture of ether, insulin, tinctures, and a great many other medicinal substances. It is also essential in the manufacture of smokeless gunpowder. It has been stated that it takes 65 gallons of alcohol for a single 16-inch shell. Molasses and sugar will be used extensively for the manufacture of alcohol and a number of other munitions substances. The government has ordered the distillers of the country to furnish 125 million gallons of alcohol this year. Following a careful survey of its uses of alcohol, the New York Hospital has been able to reduce its alcohol consumption by 50 per cent.

3. The Army and Navy have taken for immediate use and are storing up against possible future needs vast supplies of drugs and appliances, such as quinine, morphine, sulfa drugs, antitoxins, vaccines, and also bandages, gauze, ligatures, sutures, adhesive plaster, hypodermic syringes, surgical instruments, etc. It is reported to us from apparently reliable sources that within a few weeks the Army ordered 100,000 vials of tetanus antitoxin, 40 million quinine tablets, 35 million sulfathiazole tablets, and 10 million sulfapyridine tablets. Of these sulfa drugs, such quantities represent the entire medical requirement of the United

States for two to three months. We are informed that a shortage of liver extract may ensue, one cause being that the Army is feeding large quantities of liver to the troops. We are told that the orders for bandages exceed the present stocks of those in the whole country.

4. The Lend-Lease requirements are heavy and include many materials to be supplied to the whole free world. Just as one illustration of our responsibility, the plants of the only two manufacturers of insulin in Britain have been demolished, and as a consequence the British Empire is forced to call upon us for its entire requirement. Estimates of consumption and actual requirement figures for health supplies include the requirements for the Army, the Navy, and the Marine Corps, the various governmental agencies, the Public Health Service, the Red Cross, the Lend-Lease requirements for Britain, Australia, India, South Africa, China, free France, the Soviet Republic, the Central and South American republics, and other nations receiving defense aid, as well as the requirements for the civilian population of the United States and the requirements for civilian defense. After having determined what is required, there is still necessity for a study of the availability of basic raw materials and intermediates needed to produce the finished substances, and then proper allocation of these.

5. There are priority rulings on materials used in packaging, such as tinplate and lead, which are used in munitions manufacture. There are indications that the use of paper cartons, corrugated paper, and wooden packing cases will be curtailed, largely because these are needed for light-weight lend-lease shipping. Renewals of worn-out manufacturing and packaging machinery and new machines may be unavailable. From Milton H. Luce, Administrator, Health Supply Section, we learn that the Health Supplies Rating Plan has been formulated to establish priorities for steel, copper, rubber, and other substances required by the manufacturers of medical and hospital appliances, such as: anesthesia apparatus, atomizers, clinical thermometers, basal metabolism, electrocardiogram and x-ray machines, x-ray films, hypodermic syringes and needles, surgical instruments, hospital equipment (beds, stretchers, sterilizers, operating tables), hot water and enema bags, rubber nipples, rubber tubing, laboratory equipment, and many other forms of apparatus. Up to the present the Rating Plan has not included pharmaceuticals.

6. The problem of transportation is becoming critical. The railroads have been allocated a supply of new freight cars but must meet greatly increased demands. Cross-country trucks and trucks for local deliveries may be withdrawn at any time. A manufacturer or wholesaler with a supply of drugs or surgical and hospital supplies on hand may be unable to deliver them to the retailer, so it will become more and more difficult to make available for the physician even those drugs and appliances of which there is no essential shortage. One wholesaler has informed us that his firm is urging retailers to stock up for three or four months ahead, but in some instances this has resulted in a panic-stricken pharmacist ordering ten pounds of a drug of which one pound a year would meet his needs.

These will suffice to indicate the wide variety of causes for inadequacy in the supply of drugs and medical appliances.

The U. S. Pharmacopoeia is alive to the situation and is kept well informed by departments of the government: (1) It has relaxed the storage requirements and moisture content of ergot, in order to permit shipments of Spanish ergot, because in Spain there are now no facilities for packaging the ergot according to the previous strict U. S. P. requirements. (2) It has made official a substitute for codliver oil through the dilution of high vitamin oils of the haliver type with low vitamin codliver oils, or with vegetable oils such as corn oil. The price of codliver oil has advanced greatly, as the different countries are holding their own product for their own use. Germany takes the entire Norwegian output. The Iceland yield, which is of high quality, is divided equally between Britain and the United States. There may soon be a scarcity of the concentrated liver oils obtained substantially from the halibut, the percomorph, and the shark. There is a decided shortage of drop-dosage A and D oils for infants, as the only source of these oils heretofore has been the tuna fish caught off the coast of Japan. (3) It has allowed the substitution of the oils of peach and apricot kernels for sweet oil of almonds, of Indian squill for Mediterranean squill. (4) It has permitted the omission of oil of lavender, as in aromatic spirit of ammonia and liquid green soap, of oil of rose and rose-water, as in cold cream.

It is well to know that the government is alert and busy regarding these matters, which are under the direction of the Health Supply Section, War Production Board, and other divisions of the government, according to the nature of the problem. The Health Supply Section is conducting a comprehensive survey of scarce drugs, medicinal chemicals, surgical dressings and equipment, and other health appliances, and is studying the needs of the civilian population. It sends us the information that the Federal Government has accumulated stockpiles of various important agents, such as ergot, opium, and quinine, sufficient to meet the U. S. civilian and military requirements for several years but inadequate to cover the Lend-Lease needs. In addition, the industry has in its possession about one year's supply of these materials.

The program undertaken a year ago by the Health Supplies Branch, the predecessor of the present Health Supply Section, War Production Board, to foster expansion of production of such important substances as sulfonamides and vitamins, is believed adequate to meet the demands of the Army, Navy, and other defense forces, the Red Cross, the Lend-Lease requests, etc., without undue dislocation of civilian supplies. In some materials, notably vitamin A and agar-agar, the supplies are inadequate to meet the heavy demand so their use has been restricted to essential purposes.

Recommendations

Our suggestions relate to: (1) those having to do with physicians and hospital practices as they may affect prescriptions and demands for drugs and supplies; and (2) those having to do with improving the supplies.

Under the first heading we ask:

1. That hospitals and surgeons use the utmost economy in the employment of operating room and other materials and apparatus.

2. That prescriptions not be written for preparations containing alcohol, glycerin, phenol, sugar, potassium salts, and other substances to be listed in a proper publication. This involves substitution of tablets and capsules for elixirs, tinctures, fluid extracts, syrups, and preparations containing glycerin, such as rhubarb and soda mixture; substitution of sodium salts for those of potassium.

3. That physicians limit the employment of a scarce drug to its more important uses. For example, agar-agar should be reserved for bacteriological media, and not used as a bulk-producing laxative; belladonna and atropine and their derivatives should be prescribed in very limited amounts and only when absolutely necessary.

4. That prescriptions be written for small amounts rather than for quantities for extended use.

5. That there should be published a list of all drugs commonly used, and their availability. For this, valuable suggestions can be obtained from a 1941 publication of the Therapeutic Requirements Committee of the Medical Research Council of Great Britain, entitled, "Economy in the Use of Drugs in Wartime," in which all commonly used drugs are classified A, B, and C. It is a guide for physicians. Under A are those that may be prescribed because they are regarded as *essential or readily available*, such as acacia, ascorbic acid, aspirin, salicylic acid, cocaine, codeine, digitalis, theobromine. Under B are those *essential for certain purposes but widely used for other purposes* for which they are not essential. Bismuth, for example, should be limited in its employment to syphilis and certain tropical diseases, and its use should be avoided in gastrointestinal disorders, for which other substances are available. Under C are the drugs which are *not essential and do not justify either importation or manufacture*—for example, aconite, buchu, glycerophosphates, oral liver preparations, injectable iron preparations, psyllium seed, potassium salts. A comprehensive list of the more familiar drugs,

CROSS REFERENCE . . . It may be necessary at times to check the information provided in an advertisement on some particular product to be prescribed. To facilitate this a cross index of advertisers and advertised products is published in every issue of the JOURNAL. We hope you will find it a convenient and useful instrument. In this issue see pages 853 and 921.

IN WHOOPING COUGH ELIXIR BROMAURATE

IS A UNIQUE REMEDY OF UNIQUE MERIT

Cuts short the period of illness, relieves the distressing cough and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 or 4 hours.

GOLD PHARMACAL Co., New York

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

[Continued from page 918]

classified in some such manner, with suggestions for substitutes for the scarcer drugs, might be invaluable. It should be in the hands of every physician. We are informed that such a list is to be issued.

In regard to the improvement of civilian supplies we recommend:

1. That every step, including subsidizing, be taken to favor the production in this country of certain vegetable drugs hitherto imported. It is possible that eventually we may be able to produce in this country agar, aspidium, belladonna, colchicum, digitalis, ergot, hyoscyamus, and certain volatile oils, such as peppermint, needed for its menthol, and others used for their flavor and aroma. Methods of planting, care of the plants, collection, drying, and storing are being studied. Growths of digitalis and ergot are produced successfully now and can be extended. The belladonna and agar so far produced in the United States have been of inferior quality, but plans have been made for their production on an extensive scale.

2. That the Army and Navy be asked to avoid clearing out existing drug and health supplies abruptly unless this is a real necessity. They should make more gradual their accumulations for storage against possible needs a year or more hence, so as not to curtail unnecessarily the supplies needed now by the civilian popula-

tion. In cooperation with the Red Cross and the OCD they should set up a mechanism whereby in the event of a civilian catastrophe, such as an air raid, medical stores would be made immediately available.

3. That official drugs and their preparations, together with certain newer chemical drugs, be given priority over unofficial and proprietary preparations. A precedent for this has been established. Long before the war, the American Hospital Association sanctioned, and a number of important hospitals put into force, an order that in prescriptions for use in the wards medications should be limited to official medicines as listed in the U. S. P. and the N. F., together with certain selected newer remedies approved by the Council on Pharmacy and Chemistry of the American Medical Association. It is believed that these will meet all the requirements of the best medical practice.

4. That the proper government department be requested to allocate adequate distribution facilities for drugs and medical supplies.

Respectfully submitted:

WALTER A. BASTEDO, *Chairman*
BEECKMAN J. DELATOUR

New Federal Questionnaire

AN OFFICIAL enrollment form and a new questionnaire are being mailed to every licensed physician, dentist, and veterinarian. There are 186,000 licensed physicians, 71,000 dentists, and 12,000 veterinarians.

"The new questionnaires supplement those circulated as early as 1940 by the professions in order to make inventory of those available for military service," Paul V. McNutt, Federal Security Administrator, has announced. "They also supplement information previously requested by asking about experiences in foreign countries, the ability to speak and understand foreign languages, by asking about hobbies which may be of value, such as special knowledge of photography and cryptanalysis."

As part of the man power program it is "highly essential," Mr. McNutt said, that every physician, dentist, and veterinarian return the enrollment form at once. Mr. McNutt said that any physician or dentist who does not receive one by May 10 will know his name is not on record and should write for the form to the National Roster of Scientific and Specialized Personnel, Washington.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

Regional Maternal and Child Welfare Teaching Days

A Regional Maternal and Child Welfare Teaching Day was held at the Rochester General Hospital, on April 1, and at the Syracuse University College of Medicine, on April 23.

Program—Rochester Teaching Day

The afternoon session was called to order at 2:30 P.M. by James K. Quigley, M.D., president of the Medical Society of the County of Monroe—chairman, Ward L. Ekas, M.D., regional chairman in obstetrics of the Maternal and Child Welfare Committee of the Medical Society of the State of New York. Papers read were:

The Role of the Blood RH Factor in Transfusion Reactions and Erythroblastosis Foetalis.

Donald H. Kariher, M.D.

Howard A. Spindler, M.D.

Tuberculosis and Pregnancy.

John M. MacMillan, M.D.

The Care of the Premature Infant.

Herbert C. Soule, M.D.

The Diagnosis and Treatment of Thrombophlebitis.

Charles S. Lakeman, M.D.

The Treatment of Habitual Abortion.

C. Arthur Elden, M.D.

Demonstration of Case Study.

Ferdinand J. Schoeneck, M.D., associate professor of clinical obstetrics, Syracuse University College of Medicine, Syracuse, New York.

Home Delivery Demonstration and the Premature Box.

Visiting Nurse Association

The evening program was held at the Rochester Academy of Medicine—chairman, Albert D. Kaiser, M.D., regional chairman in pediatrics of the Maternal and Child Welfare Committee of the Medical Society of the State of New York. The address of the evening was:

Prolonged Labor: Etiology and Management.

Harvey B. Matthews, M.D., clinical professor of obstetrics and gynecology, Long Island College of Medicine, and attending obstetrician and gynecologist, Long Island College and Methodist Hospitals of Brooklyn, Brooklyn, New York.

Program—Syracuse Teaching Day

The afternoon session was called to order at 1:30 P.M. by Edward C. Hughes, M.D., regional chairman in obstetrics, Maternal and

Child Welfare Committee of the Medical Society of the State of New York—chairman, Henry W. Schoeneck, M.D. Papers read were:

The Role of Vitamin K in Cerebral Hemorrhage of the Newborn.

Tyree C. Wyatt, M.D., associate professor of clinical pediatrics, Syracuse University College of Medicine, Syracuse, New York.

Erythroblastosis Foetalis.

Merton C. Hatch, M.D., assistant professor of clinical obstetrics, Syracuse University College of Medicine, Syracuse, New York.

Charles A. Lippencott, M.D., resident obstetrician, Syracuse Memorial Hospital.

The Problem of Chronic Vascular Disease in Pregnancy.

Charles H. Peckham, M.D., Mary Imogene Bassett Hospital, Cooperstown, New York.

Retained Placenta.

Karl Miller Wilson, M.D., professor of obstetrics and gynecology, University of Rochester School of Medicine and Dentistry, Rochester, New York.

Blood Concentration: Determination by Hematocrit and Falling Drop Method.

Robert K. Brewer, M.D., professor of chemistry, Syracuse University College of Medicine.

Fluid Therapy in Obstetrical Shock and Hemorrhage; Use of Hematocrit.

Glenn A. Wood, M.D., attending obstetrician, General Hospital of Syracuse.

A social hour was held at the Hotel Onondaga at 5 P.M., followed by dinner. The chairman was Brewster C. Doust, M.D., regional chairman in pediatrics, Maternal and Child Welfare Committee of the Medical Society of the State of New York.

Question Box.

Directed by Charles A. Gordon, M.D., Brooklyn, New York, chairman of the Committee on Maternal and Child Welfare of the Medical Society of the State of New York.

EFFECT OF THE WAR ON CONVENTIONS

What effect is this war situation having on an American institution—the convention? In a matter so necessary to medical organizations, it is interesting to note what has taken place thus far in this business of holding conventions and to speculate on what may occur if the war continues for any great length of time.

The February issue of *World Convention Dates* has pointed out that of 2,688 conventions reporting during December and January—only 55 were cancelled. On the other hand, there were 83 more conventions scheduled than in the same period in 1941. Yet other groups have deferred making plans at their usual time and appear to be awaiting developments.

Several associations have moved the location of the annual meeting from coastal cities to places inland or in the Central States.

Generally those cancelling meetings are rather unimportant, such as The Young Buddhists League and the American-Japanese Conference. Then, too, with the curtailment of production and sales of many commodities it may be expected that many business associations will have little need for business meetings.

A neutral survey of recent conventions disclosed, however, that attendances were the largest on record. So it appears that any change in the convention picture has been in the improvement column.

FALKIRK IN THE RAMAPOSS

A sanitarium devoted exclusively to the individual treatment of MENTAL CASES. Falkirk has been recommended by the members of the medical profession for half a century.

TRAVEL MEDICINE

How Travel Benefits a Nation at War

The effect of travel upon the economic life of the nation is outlined in a recent issue of *The Travel Agent* in an article by Don Thomas, Managing Director of the All-Year Club of Southern California.

In normal times, declares the article, recreational travel performs three basic economic functions:

1. *It maintains retail trade levels* in the thousands of resort areas throughout the nation and along the feeder routes to these places.

2. *It maintains capital investment values like real estate throughout the nation.* Thirty billions invested in capital structures service recreational travel. Real estate values are increased in any areas to which, or through which, recreational travel flows.

3. *It produces taxes supplementing regular taxes.* It makes for a more equitable distribution of the entire tax load. In Southern California alone, recreational travel provides 19 millions annually in taxes. If these taxes were not paid by it, agriculture there would be saddled with an additional tax burden in like amount or suffer curtailment in government service.

In this war era, however, recreational travel fulfills four additional economic tasks:

1. The Congress is appropriating vast sums of money for war production. This money comes from the pockets of all the people throughout the entire country, but the

money is being spent in relatively few isolated areas. In these areas purchasing power is piling up. *Recreational travel has the ability to spread widely back over the nation* most of the taxes of all the citizens spent for industrial war production in a few industrial areas.

2. *It can bring purchasing power to those areas partially impoverished* by (a) curtailment in the production of consumer goods or (b) other economic dislocations arising out of the war.

3. Today wages are going up, so is farm income, yet the government continues to curtail items which people can buy. If they purchase recreational travel they will be making an anti-inflationary move because it lessens the pressure on the demand for consumer goods above normal needs.

4. Today, transportation and other phases of recreational travel are heavily taxed, thus, if people purchase recreational travel the Government has one of its very best opportunities to get a high tax return from consumer spending.

Woman's Auxiliary

To the Medical Society of the State of New York

LAST CALL for reservations for the Twentieth Annual Convention of the Woman's Auxiliary to the American Medical Association, which will be held at Haddon Hall, Atlantic City, New Jersey, June 8-12.

Atlantic City extends a hearty welcome to you.

County News

Albany. At a recent meeting Dr. Basilia Lipetz addressed the auxiliary on "Mental Hygiene in War." Mrs. Alfred L. Madden, Mrs. Albert Vander Veer, II, Mrs. William J. Fitzgerald, Mrs. John B. Horner, Mrs. Arthur Holding, Mrs. James Bucci, Mrs. William Feltman, and Mrs. Walter Reynolds attended the State Convention in New York.

Broome. Auxiliary members are addressing one another by their first names—"Ann," your state publicity chairman, was delighted to receive such a friendly greeting.

Cattaraugus. The executive board met at the home of the president, Mrs. E. C. Moore, in Olean. A delicious luncheon was served by the hostess. The April meeting will be held in Gowanda. The main feature will be a tour through the State Institution, conducted by Dr. Paul J. Tomlinson. The board also made plans for a dinner to be given in honor of the husbands of the members. On this occasion, Dr. Norman Peale, pastor of the Marble Collegiate Church in New York City, author, lecturer, and technical director of the moving picture, "One Foot in Heaven," will be the guest speaker.

Columbia. The April luncheon meeting was held at the General Worth Hotel. Mrs. Alfred Madden of Albany, state chairman of legislation, was the guest speaker. Mrs. Madden urged the auxiliary members to keep an active eye on medical legislation and emphasized the fact that any legislative activity undertaken by the Auxiliary is first submitted to the legislation chairman of the Medical Society of the county of which the auxiliary is a part. In a graphic manner and with many humorous touches, Mrs. Madden outlined the procedure of the introduction of bills and made a number of amusing references to the "log rolling" that frequently prevails.

Erie. The members of the auxiliary have given tirelessly of their time and energy to aid in war work. The annual Wistaria Ball was held at the Hotel Statler, April 11. Everyone who attended the Convention at Buffalo can picture the beautifully decorated ballroom.

Essex. The meetings are held twice a year in Essex County. The members stand in readiness to do their part in any emergency which might arise.

Jefferson. Dr. Eugene Bogardus of the Onondaga County Tuberculosis Sanatorium was guest speaker at a meeting and dinner held at the Jefferson County Sanatorium.

Kings. The programs presented are most interesting. The following is the spring and Easter one: "What Is a Mobile Canteen?" by

Mrs. Edward Grobert, cochairman of public relations of the American Red Cross; "Organized Medicine Looks at the Social Security Act," by Mrs. Mortimer Kopp; and a book review by Mrs. Earle F. Whitaker.

Nassau. The auxiliary's annual meeting will be held, Tuesday, May 26, at the Nassau Hospital Auditorium, at 8:45 p.m.

Niagara. Erie and Niagara county medical societies and auxiliaries held a joint meeting at the Hotel Statler, Buffalo, on April 13. Dr. W. W. Bauer of Chicago, director of the American Medical Association Bureau of Health and Public Instruction, was the speaker. The county auxiliary assisted in the registration for volunteers for defense.

Onondaga. Mrs. Mortimer G. Browne opened her home for the April meeting. Mrs. Ellery G. Allen, chairman of legislation, was in charge of the program. Assemblyman Frank J. Costello spoke on "Civics." Plans were made for a dinner in the ballroom of the Hotel Syracuse, to honor the guest speaker, Dr. W. W. Bauer of Chicago, director of the American Medical Association Bureau of Health and Public Instruction. The members of the executive board, eight delegates, and eight alternates will attend the state convention.

Orange. On April 2, a meeting was held at the home of Mrs. Harry F. Pohlmann. At this meeting arrangements were completed for the state convention to be held April 27-30, at the Waldorf-Astoria. Tuesday, May 19, was chosen as the date for the annual health forum which is sponsored by the auxiliary and held at the Middletown State Hospital. Dr. Percival H. Faivre, who is connected with the State Hospital in Middletown, spoke to the women on present trends in the treatment of the psychiatric patient. Mrs. W. W. Davis and Mrs. P. H. Faivre presided at the tea table during the social hour which followed.

Queens. Two thousand hours of production have been completed by the members of the auxiliary during the month of March. Two hundred and fifty books and magazines have been collected for service men. At the next meeting cigarettes and chocolates will be collected. Dr. Grace McLean Abbate, consultant for the Child Guidance Bureau of the Board of Education in New York City, gave a survey of the work done by this bureau. On May 19, a luncheon and bridge are planned by Mrs. Mildred Pollock. This party will be held at La Guardia Field. Queens County Auxiliary has its own Red Cross unit, and is sponsoring first-aid classes.

Schenectady. The newspaper accounts show that the two-day nutrition institute was a big success. The high light of the first session was a discussion on "Nutrition and Defense." "A Study of Victory Gardens" was another feature. Expert advice was given on preserving foods.

Warren. Warren, Washington, and Saratoga

Increasing Nurse Shortage

The problems of the doctor, the nurse, and the hospital are all closely interwoven in the community mind. To solve a problem of the one without the aid and cooperation of the other two factors is obviously impossible. Today, the call of the armed forces upon our normally balanced supply of doctors and nurses is producing imbalance in communities. How, can, and will we meet our obligations in the care of the sick and still supply adequately balanced service at home and to the armed forces?

For the medical needs of the Army a Procurement and Assignment Service has been set up and should adjust the needs for physicians. To date, the Navy has had little difficulty in getting personnel.

Nursing is causing us the greatest concern. According to the Army reports, they have 9,000 on duty, and need 10,000 more by July 1, 1942. The Navy has about 2,000 on duty and needs about 750 more by July 1, 1942. It is estimated that these needs of the Army and Navy will be doubled in 1943, with further increases in 1944. In addition to the above, Public Health will require 3,000 or more additional nurses.

There is already a nurse shortage of approximately 17,000 in hospitals. The students graduated from schools of nursing every year in the U. S. A. are approximately 30,000. If these were all eligible and unmarried, they might almost meet the need of the armed forces and the hos-

pitals. However, this is not feasible or possible. Many cannot pass muster physically, many will marry, and others do not want military service.

Adding students to our schools or setting up new schools, or even shortening the course, offers no immediate relief to our shortage. Many schools have added extra students during the last year. Many more can expand by a small percentage with financial aid. This may help the hospitals to a small degree but is in no way to be considered as even a partial solution of the impending total shortage of nursing personnel.

In New York State there are about 56,000 registered nurses in active practice. Of these, 30 per cent are in institutional service, i.e., regularly employed in hospital service. Another 6 per cent serve as technicians in anesthesia, x-ray, laboratory, and similar services. About 8 per cent are employed in Public Health or industrial work. The remainder are on our various nursing and commercial registries as special-duty nurses. This latter division is our largest single group of nursing personnel available to be called upon to meet the shortage for both military and civilian needs. Even though a considerable number are unsuitable for institutional service, they still can render good home care service and relieve younger nurses for war duty.

The use of special-duty nursing in most of our institutions and in the home can be

[Continued from page 924]

counties gathered together to hear Mrs. George B. Adams, state President. Mrs. Adams addressed the group on the theme "Auxiliary Work in the State During War Times." Forty-four members attended this meeting.

Washington. Mrs. George B. Adams was the speaker and guest of honor at the spring luncheon held at the Queensbury Hotel, Glens Falls. Mrs. Irwin Decker, vice-president, presided in the absence of Mrs. Creevey. The May 19 meeting will be held at the home of Mrs. M. A. Rogers at Greenwich.

Fulton, Montgomery, and our new county, Livingston, have been doing their bit. We appreciate their work and cooperation.

The following poem was written by Mrs. (I. V.) Eudora R. Decker, Salem, New York. (Mrs. Decker is from Washington County.)

IS IT WORTH IT?

Is it worth it,
When there's so much stress and strife?
Is it worth it,
That for every doctor's wife,

Comes the clarion call to be,
Helper of humanity,
Grouped, and individually?

Is it worth it?

Is it worth it,
When there's so much else to do?
Is it worth it,
When the members are but few?
Should we ever hesitate,
Or consider, and debate,
Whether it will compensate?

Is it worth it?

Is it worth it,
When we stop and think that we
Can accomplish
through our own Auxiliary
Aid for doctors everywhere,
Thus their burdens come to share,
Proving that we really care?

Yes, It's worth it!

—Eudora R. Decker

DENTIST GOES TO PATIENT

Late in 1940, the Division of Maternity, Infancy, and Child Hygiene of the New York State Department of Health inaugurated a dental trailer service to provide dental health education and facilities for the correction of dental defects in preschool children in upstate areas which were without dental personnel.

During 1941, the first full year in which the trailer has been in operation, dental clinics were conducted by the senior dentist in charge in sixteen townships of five counties. Completely fitted with the most modern dental equipment, the trailer has functioned in the following places: Hamilton County—Long Lake; Chautauqua County—Ripley, Ashville, Bemus Point; Livingston County—York, Leicester, Groveland, Springwater, Ossian; Tompkins County—Ludlowville, Dryden, Newfield, Slatersville Springs; Ulster County—East Kingston, Port Ewen, Phoenicia.

In the course of the clinics, 296 children made 1,682 visits to the trailer and 2,705 dental operations were performed, including 207 extractions, 1,684 fillings, 286 x-rays, 53 cement bases; 160

anesthesias, 16 temporary dressings, and 299 silver-nitrate treatments. Approximately 90 per cent of the children attended the clinics until the necessary work had been completed.

The dental service is rapidly becoming an important feature of the established antepartum clinics and child health consultations. The main objectives of this program are education of the laity and professional groups, and provision of dental care for expectant mothers and children of preschool age who cannot obtain such care for themselves.

The educational program for nonprofessional groups is carried out by lectures to organizations such as parent-teacher associations, mothers' clubs, service clubs, school groups, and 4-H clubs. The lectures are supplemented by moving pictures, models, and charts. Individual health talks are given to expectant mothers and to parents or guardians of preschool children who are examined by the dental hygienists. Professional education includes refresher courses in children's dentistry and institutes for public health nurses.

ANALYSIS

This happened some time ago, and in another city, so it's no use trying to fill in names. Seems that two famous psychiatrists had come to town for a conference of physicians and were staying at the home of a doctor whom they had known in medical-school days. One of them was having a cocktail with his hostess when the other tottered in with the announcement that he had a terrible headache and would like to lie down before dinner. After he had gone upstairs, the other psychiatrist said, confidentially, "Don't worry about him. He's always like this when he's been

showing off. You see, he made himself conspicuous at the meeting today, and his guilt reaction has taken the form of a headache." The hostess nevertheless went upstairs and peeked into the darkened room of the ailing psychiatrist to ask if he needed aspirin or a cold cloth. "No, no, I'm all right," he said with a brave smile. "You go down and talk to him. He's so terribly in need of wholesome diversion. Though I must say," he added, "the poor chap's been acting more normal lately than I've seen him in years."

—Reprinted with permission from *The New Yorker*

mode of economic thinking. Our economy, because of this total war, is or should be dedicated to the production of an abrupt fall in the standard of living. This fact has been played down, by-passed, hinted at obliquely. As a result, it is our belief that many medical men in considering the question of the maintenance of their dependents, should they be commissioned for service, have thought in terms of the now nonexistent standard of civilian living. Dependents will not live from now on at the old level; they will do without many things; they will make many old things do or go without. Furthermore, they will do this cheerfully; they are Americans.

We urge upon the readers of these pages

some realistic thinking along these lines. There is a job to do. It must be done quickly. We feel that it will be done quickly, that medical men will do it, as they have always done it when their thinking on the subject of their prior obligations has become clarified.

They do not need to be told that already the United States Navy has lost about 5,700 men, including 2,400 killed, 2,300 missing, and 1,000 wounded—said to be more than the total naval casualties hitherto in the history of the Nation—to have impressed upon them the serious need for services such as only they can render. No physician worth the name takes his obligations lightly—either national, professional, or personal.

The Doctors' Orchestra

This JOURNAL conveys to the leader, Fritz Mahler, and to the several members of the Doctors' Orchestra for their exceptionally fine concert at the Annual Banquet on Tuesday evening, April 28, the appreciation of the Medical Society of the State of New York and of its distinguished guests.

The amazement expressed by Major General Lewis B. Hershey, in his address, that so many physicians could be found who would all consent to play the same piece of music at the same time is as nothing compared to ours that they should have done so with the finished skill and sympathetic interpretation which they exhibited. This is a very sincere tribute to the leadership of Fritz Mahler; for the discipline of his sections was extraordinary and especially noticeable in the many unison passages for the horns, cellos, and violins. That some timidity characterized the performance of his woodwind section is not really remarkable. It is to be found at times in the best of orchestras, in which, regrettably, may be noticed these "ill wood-winds that nobody blows good."

The "Overture" to *Euryanthe* of von Weber was performed in a workmanlike

manner and served admirably, without noticeable emotional content, as a warm-up.

The *Unfinished Symphony* of Shubert was admirably performed. The difficult unison passages for cellos and brasses were well handled, with splendid body of tone and authority of execution. There was no compromise in the matter of tonality, frequently the chief fault of non-professional as well as professional symphonic groups. Attacks were precise and incisive, and the antiphonal work of the various choirs left little to be desired. Especially commendable in this selection was the work of the first violin section and the violas. Tone production was smooth and of good quality, well sustained throughout. This writer has rarely listened with more real enjoyment and esthetic satisfaction to a performance of this difficult and gracious symphony.

The "Marche Slave" of Tchaikowsky opened well. Cues were well integrated and a noticeable and commendable brilliance of tone characterized the performance, with noteworthy work by the brasses in ensemble but which wavered in the solo passages. Orchestral discipline was not so noticeable in this final work.

shown to be very largely a luxury service, especially after the first few days of acute illness. It may easily become a luxury to the patient and a waste of nursing personnel, because the medical and nursing needs of the patient cease to be great enough to require the full time of one to three graduate trained nurses devoted entirely to a single individual's care. Of course, it is nice for the patient, convenient for the doctor, and many patients accept the service whether they or the family can afford it or not.

There are several ways in which we as physicians, the hospitals, and communities can anticipate the possible declaration of special-duty nursing as a luxury by the government and even adjust ourselves to such a change before it happens.

Physicians in their offices frequently use graduate nurses as secretaries and for other duties in which their nursing training is partially or wholly wasted. Institutions do likewise in their admitting and other services.

We might urge that married nurses, who constitute about 40 per cent of the entire graduate group, be used in the Army, especially for duty in the camps in the U. S. A.

In institutions, we could give the pa-

tient more bedside nursing if our doctors doing research or prescribing complicated technics would cooperate, through simplification of procedures, and curtail some of the less necessary research until after the duration of the war.

Physicians should use graduate nurses in home nursing, and, where technical skill is called for and a practical nurse would not suffice, they should advise their patients to conserve on nursing if practical so as to free as large a group for war service as possible.

There is no need to reduce the standards of nursing education or the requirements of bedside patient care if we will but streamline the service to necessities and trim away some of the nonessentials we have built up in the time of plenty—now past for the present at least.

Only through the utmost cooperation among the medical, hospital, and nursing groups of the community can we stretch our existing supply of nurses and solve this problem as it should be solved; viz., by those who know the needs locally, not by some over-all agency. Talk won't do it. Let's have some action, both local and state. Our state organizations should join together and begin a militant campaign at once.

Dependents

The impending necessity for many physicians to enter the armed services raises the question of the maintenance of dependents. Numbers of medical men do not view the pay and allowances of army service in the lower officer grades as adequate to maintain themselves and to provide support for those dependent upon them. This, of course, is a matter which varies in each individual case, and must be considered apart from other factors which might becloud the issue.

Most of the medical men under and over forty years of age have lived in this country in an economy which has flagrantly boasted of a high standard of living. It has been drummed into them that this was "The American Way of Life."

Particularly during the last twelve years, the ingenuity of the leaders of political and economic thought has been exercised in heroic efforts to raise this standard. It is therefore not at all surprising that at the present time when many physicians are revolving in their minds the problems related to the maintenance of their dependents that they think in the terms in which they have been educated to think by every means at hand—the press, the radio, the forum, the pump priming, the expanded public works program, and the "social gains."

It has not yet penetrated to the consciousness of many people that the total war in which we presently find ourselves engaged requires a radical reversal in our

SOCIAL ASPECT OF HEART DISEASE IN INDUSTRY

F. HOWARD WESTCOTT, M.D., F.A.C.P., New York City

THE financial liability incurred in the employment of an individual with a heart condition is important to institutions maintaining a disability payment and insurance plan. No satisfactory statistical data are available for determining the work expectancy in this condition, as compared with the data upon which life expectancy in heart condition is computed by life insurance companies. During the past nineteen years, an accurate medical and financial record has been kept by the New York Times Medical Department* on 564 individuals who have heart disease.

From the data accumulated in these files, the material relating to all individuals having a basic heart history or lesion on record, as well as to those that have acquired heart symptoms during their employment, has been selected for analysis and comparison with data on individuals of other groups as controls.

The objects of the present study are:

1. To determine what assistance we as physicians can give to the prospective employee who has potential or real heart disease, in choosing a type of work suitable for his physical future.

2. To learn how soon these employees are rendered unfit for work by heart disease, if they can be employed only at work they are physically incapable of doing over the normal span of working years.

3. To set up a system whereby all can be gainfully employed, irrespective of physical condition, in types of work least harmful to any existing heart lesions.

4. To obtain reliable figures on our experience, so that employers of large groups can make proper financial allowance for disability due to heart disease, particularly in institutions where physical examinations are not required or where workers must be accepted under labor codes, irrespective of the physician's physical findings and advice.

5. To determine whether it would be best, for serving all concerned, to coordinate our efforts with those of the individual, the employer, the employees' self-chosen protective

organization, or of a combination of these units.

A previous study of a 12-year period¹ revealed that 75 per cent of all time loss was due to illness, as compared with 25 per cent due to accidents. A total of 8 per cent of this disability was due to heart disease.

Many persons who were known, either by history or physical signs, to have some predisposition to cardiac conditions were employed and given class D or C ratings. All normal persons were rated as class A or B.

Among 919 of our workers who were employed before medical examinations were required, 200 have reported to the Medical Department, or have presented medical certificates from their family physicians, with diagnoses of cardiovascular disease between 1921 and 1940. In 1939 the average length of employment of the workers was 22 years and their average age 62 years. Of these 200 persons who are known to have had symptoms of heart disease, 67, or 34 per cent, have lost no time up to this writing because of those symptoms. The remaining 133, or 66 per cent, have lost a total of 16,597 days because of cardiac or some directly related illness. Computed on the basis of an average salary of \$7.00 a day, this amounts to a loss of \$116,179, or an average of \$873.52 for each cardiac losing time. This means a liability of \$580.89 for each cardiac irrespective of lost time, and \$126.41 for each employee hired without examination over a period of 19 years.

At the present writing, these 200 employees are distributed as follows: 99, or 50 per cent, are still employed with us and are working; 39, or 19 per cent, are not working (32 having been pensioned because of age or disability, and 7 being no longer employed with us for various individual reasons other than health); 12, or 6 per cent, have died from known heart disease while 8, or 4 per cent, have died from other diseases and 42, or 21 per cent, of unknown causes, making a total of 62 deaths.

During the same 19-year period, we have examined 2,719 applicants for employment, classified as follows:

Group A: 619 having normal history and physical findings.

Group B: 1,454 having normal history, but minor physical defects easily correctable—i.e., diseased tonsils, dental caries, etc.

* The Medical Department was organized in 1921 after the establishment of a plan of disability payments for the employees of the New York Times. A physical examination of applicants for employment was adopted, and a history file on all new employees, from the date of their employment, has been kept up to date. Medical histories of previously employed members of the organization have been kept from the date of their first reported illness after 1921 up to the present time.

Nevertheless the body of tone was admirable, and the fire and spirit with which it was played more than made up for the few technical faults.

Medicine and music are inseparable. The physicians of the State of New York should be proud to have such an organization as the Doctors' Orchestra to rep-

resent them. We feel certain that the spirit of Borodin, of Bach, and the incomparable Peter Ilyitch will bless the devoted labors of this organization. This JOURNAL solicits in behalf of this fine orchestra the continuing interest and appreciation of the medical profession in the State of New York.

Recent Legislative Enactments

The 1942 Legislature, which adjourned on Friday, April 24, enacted several very important measures which will be of particular benefit to the public and to the medical profession, and at the same time it maintained a record of years' standing in defeating a number of attempts to lower the quality of medical care to which the State is accustomed.

Among the bills that have been left for the Governor's approval is an amendment to the Medical Practice Act affecting the Grievance Committee. The Committee, composed of nine physicians and one osteopath, has fully realized the hopes of the framers of the Act in the fifteen years since its passage, but later amendments to the law have unexpectedly extended its responsibilities so that it has become necessary to modify certain of the law's provisions. For final action on any case the law now requires that each of the ten members be present and voting at the time.

Since these are all busy men, it has been found difficult to hold meetings where all ten can be present; hence an amendment was prepared last year at the suggestion of the members of the Grievance Committee and endorsed by the Regents, which provided that final action might be taken when two-thirds of the members are present. To offset any remote possibility of unfairness, the bill which passed the Legislature this year pro-

vides that the evidence in each case shall be taken initially by a subcommittee of three who shall agree unanimously upon the report submitted to the entire Committee.

Two other important bills that have been submitted to the Governor for his approval are an outcome of the investigation made by the Commission appointed by the Governor to inquire into irregular practices in Brooklyn. They amend the Education Law and the Penal Law so as to give law enforcement officers a better opportunity to discover and convict abortionists.

The principal threat to the educational standards of medical care, which protect the public, lay in the chiropractic bill, which was effectively defeated.

It is with considerable satisfaction that we report the foregoing facts. In such times as these, increasing demands upon the medical profession and the turbulence associated with profound economic reversals warrant a more than usual awareness and careful watchfulness, especially with regard to the maintenance of the educational standards of the medical profession of the State. It is to be hoped that the inevitable drop in the standard of living consequent upon the prosecution of the war will not affect the high standards of thinking which have always been the rock of security upon which the medical profession has built.

TABLE 2—CARDIAC SURVEY OF PRE-EXAMINED EMPLOYEES, 1921-1939

No of Employ- ees According to Medical Rating	Total Years of Employment	No of Employees Who Have Lost No Time	Lost Time	Total Time Lost (Days)	No Working	No of Employees Removed	Died	Cost per Man on Average- Salary Basis (\$7.00 a Day)
A rating 19	238, av. 12 1/2 yrs per person	(74%) 14	(26%) 5	106	(69%) 13	(26%) 5	(5%) 1	\$ 39.05
B rating 114	1,133, av. 10 yrs. per person	(63%) 72	(37%) 42	3,911	(59%) 68	(24%) 27	(17%) 19	\$240.10
C rating 145	1,302, av. 9 yrs per person	(86%) 123	(14%) 22	1,684	(63%) 92	(27%) 38 { P-1 } { R-37 }	(10%) 15	\$ 81.29
D rating 86	315, av. 3 1/2 yrs. per person	(98%) 84	(2%) 2	900	(27%) 23	(67%) 58*	(6%) 5	\$ 73.25

rule, we had willing cooperation from all concerned, because of our attitude of keeping the family physicians informed of our findings and of encouraging our employees to visit the latter whenever we felt that medical attention was needed.

The following table shows the distribution of the types of heart disease found among all employees who were adequately enough observed to permit making diagnoses with assurance. Clinical histories, repeated physical examinations, and electrocardiographic tracings were made in the Medical Department whenever indicated.

TABLE 3.—DISTRIBUTION AND CLASSIFICATION OF CARDIAC DISEASES OCCURRING AMONG EMPLOYEES 1921-1939

Diagnosis	As a Primary Condition	As a Com- plication
1 Rheumatic endocarditis with mitral insufficiency, mitral stenosis, etc.	6	
2 Rheumatic myocarditis	4	2
3 Arteriosclerosis with or without hypertension	22	8
4 Hypertension, essential	5	2
5 Coronary sclerosis	3	7
6 Coronary thrombosis		4
7 Angina of effort (pectoris or spasm)	3	5
8 Myocarditis, chronic, with or without decompensation	11	20
9 Auricular fibrillation secondary to	8	4
(a) rheumatic myocarditis	5	1
(b) thyrotoxicosis	3	3
10 Luetic heart disease	2	
11 Unclassified heart disease	2	3
Total cases	66	

Of these 66 cardiacs, 32 died up to 1939, and 7 were pensioned because their cardiac condition incapacitated them; 21 of them are still working, and as far as we can tell are well compensated, and one is known to be decompensated at this writing. The remaining 5 are

apparently alive but their condition is not known to us. The average age of onset of symptoms in these 66 patients was 54 years, and they were able to work an average of 6 years after the discovery of their symptoms. The deaths occurred on an average of 5 years after discovery of heart trouble.

Conclusions

1. Illness accounts for 75 per cent of lost time in a large commercial organization, as compared to 25 per cent lost by reason of injuries. About 8 per cent of total time loss is due to cardiovascular disease.

2. The amount of time lost for cardiac disease is greatest in the case of the unexamined and unselected employees and least in the case of those employed as group A risks.

3. The percentage of cardiacs losing time is smallest in the D group—those not covered by disability—and highest among the older employees entitled to all disability benefits.

4. Chronic myocarditis with decompensation and arteriosclerotic cardiovascular disease constitute at least 50 per cent of all cardiac disability.

5. By selective physical employment and a graded sick benefit plan, those employees liable to lose time because of heart disease other than from acute accidents, can be segregated and given gainful work of a type in which further damage to a diseased heart is avoided. Such a plan of employment eliminates the danger of setting up a social and economic inequality in the case of certain applicants.

200	4,451, av. 22 yrs. per person	Lost No Time (34%)	Lost Time (66%)	16,597	Working (50%)	Removed (19%)	Died (31%)	\$580.89
		67	133		99	39 { P-32 } { R-7 }	62	

Group C: 422 physically able to work, but having some physical defect not impairing health and not easily corrected—i.e., deformities, old injuries, poor hearing, etc.

Group D: 224 rejected for employment because of physical defects or histories of conditions which caused them to be risks.

In groups A and B, the average time lost for all medical illness was very low, and the percentage of time lost for cardiac disease was due to those unavoidable emergency cardiac failures or heart attacks unpredictable by either physical examination or recent history.

Out of the total of 619 employees with A ratings, only 19 have reported to us with any cardiac symptoms or medical certificates indicating that they had been ill with any related disease. Of these 19 only 5, or 26 per cent, have lost a total of 106 days, at a cost of less than \$1.20 a year per man for the total group. This represents a negligible amount and cannot be reduced by any improved methods of diagnosis or pre-employment examination.

Of the 1,454 group B employees examined, 114 were found to have heart ailments. Of these, 72, or 63 per cent, lost no time; 42, or 37 per cent, lost a total of 3,911 days because of heart ailments. The average length of employment in this group was 10 years, and the cost per man for the whole group amounted to \$18.82 a year.

Among the 422 group C employees, 145 were employed with histories of rheumatic fever or other heart-damaging childhood disease, or with known cardiac abnormalities, such as a heart murmur, irregularity of rate or rhythm, and elevated blood pressure above the high normal. The average length of employment for this group is 9 years, and their average age in 1939 was 59 years. One hundred and twenty-three, or 86 per cent, have lost no time because of heart trouble, and the remaining 14 per cent have lost 1,684 days because of cardiac or directly related conditions, at a cost of \$11,788. This makes average cost for the groups as follows: (1) \$579.81 for each cardiac losing time; (2) \$143.55 for each cardiac employed irrespective of loss of time; (3) \$27.88 for each C-rated employee per year.

During this 19-year period the average cardiac with C rating worked for 4 years after his first heart-disabling illness. (Deaths are too few to be of any statistical value.) At the present time 92, or 63 per cent, of these cardiacs are still working, and 37, or 26 per cent, have been removed for causes other than health (average turnover probably accounts for this loss of employees). Fifteen, or 10 per cent, have died; 7, or 5 per cent, of these were cardiac deaths directly associated with the loss of time.

The D cases present a different type of study, because they were all poor risks to begin with, or became D cases because of illness which caused them to use up all their disability pay. Employees are given this rating for any one or more of the conditions listed previously as "causes for rejections."

During this 19-year period, 224 employees were so classified, and 86 of these have been considered as having some cardiac disability. These 86 have worked an average of 3½ years to date, and only 2 per cent have lost any time because of the heart conditions. This very low morbidity rate is difficult to explain on a scientific basis, but economically the answer is evident. It has been our observation that, under our present system of sick benefit payment, many days are lost for minor illnesses or conditions, which under a nonpayment system would not be lost. This group should, according to their histories and our physical findings, have had a much higher percentage of time lost than the A, B, or C groups. The one great difference lies in the matter of compensation. The latter groups, being entitled to sick benefit, are quicker to stay away, while the D cases, being not so fortunate, work in spite of minor health disabilities.

The problem of making a correct diagnosis in heart disease is difficult in any group where a fair percentage of patients are not seen by the examining physician until after their acute episode. Our best methods of checking were through direct contact with the family physicians, by way of written medical reports, telephone conversations, or through visiting nurse service from the Medical Department. As a

FIG. 1. Schematic drawing to show how foot rotates internally and externally under talus between normal positions of varus and valgus heel.

impression. Some authors have reported areas of blood blisters or hemorrhage in the tissues of the feet at the site of contracture.

Principles of Correction

The principle which underlies the correction of the deformities is, in brief, a slow stretching of the contracted tissues in the line of normal joint motion. The deformed section of the foot is pulled away from its bent position, carried well past the neutral mid-joint position, and pulled around to the opposite limit of the joint motion into a position of overcorrection. There it is held for a long period of time, usually three months, until the foot has had some opportunity to grow and further nullify the effect of the contracture which causes the deformity.

It is a property of all fibrous tissue to contract upon itself unless it is stretched. But stretching the part to its full limit of motion twice a day will usually prevent recurrence of any contracture. This contracture area, however, does not stretch with growth as well as normal tissues. As the foot continues to grow in length, there is a definite tendency for the distal segment of the foot to swing back into its old deformed position. This tends to occur with each period of rapid growth in the child; therefore the foot must be stretched daily for years. If this stretching regimen is carried out religiously by the mother, it is rare to see a deformity recur. The corrective shoes prescribed for the child are an aid in carrying out this principle, and they hold the foot in a position which is slightly corrected past the neutral.

Operative correction of the feet in these very young children is not done as much now as in previous years. The results have not been as good as with the slower plaster-cast stretching. It is true that when an untreated

clubfoot is seen in an older child, an operation may be necessary, but in general it may be stated that a child seen at birth and treated immediately should not have to expect surgery.

In the plaster-cast treatment of clubfoot, the varus deformity is usually easily removed. So is forefoot adduction and the cavus element. But the equinus contracture as a rule will either come out immediately or will cause a lot of trouble. If the wedging and stretching to correct equinus is done in a faulty axis, not in the line of normal joint motion, the ligaments may give way in the process before the equinus is removed and a "rocker foot" will result. Then it is almost impossible to remove the equinus without surgery. Therefore, when correction of the equinus is contemplated, the axis of stretching must be considered with more than usual care.

The forefoot adduction lends itself easily to correction, but to maintain this corrected position is another story. The foot must be constantly observed through the growth period, and frequently the x-rays will show more recurrence than can be seen by clinical examination.

Roentgenograms

Roentgenograms are important in the treatment of foot deformities. In any obvious deformity, they should be taken as a matter of record for future reference as the treatment progresses. In mild deformities, which represent only a "tendency" clinically, the roentgenogram may show considerable actual change present. Many feet appear corrected clinically, but are seen to be insufficiently corrected when the roentgenograms show the true state of affairs.

The salient points to observe in the anteroposterior roentgenograms are (1) the angle the talus makes with the calcaneus in the anteroposterior view, and (2) the position of the forefoot on the heel.

The anteroposterior view measures the rotation of the foot under the talus. The talus is the fixed point, since it is held immobile in the ankle mortise. Therefore, if the calcaneus makes a severe angle with the talus, it is rotated under it. It may be rotated either internally to produce a varus foot or externally to produce a valgus foot. This anteroposterior view also shows the degree of forefoot adduction or forefoot abduction on the calcaneus. Normally, the long axis of the calcaneus points down the fifth metatarsal. If the films show the metatarsals deviating

THE MANAGEMENT OF FOOT DEFORMITIES IN THE NEWBORN

FREDERICK R. THOMPSON, M.D., Sc.D., New York City

THE foot of a normal newborn infant is extremely flexible in all directions and presents a wide excursion of motion. It can be swung into such extreme valgus that the toes touch the lateral surface of the tibia, or into such varus that it looks like a severe clubfoot.

A deformity of the foot in the newborn is essentially a contracture, holding a section of the foot in a position which is a part of its usual range of normal motion. The diagnosis of a deformity, then, is made when the foot cannot be passively corrected with the examining hand past the neutral foot position into overcorrection. If the contracture is on the medial side of the foot, the deformity is a metatarsus adductus. If it occurs more extensively on the medial side and farther posteriorly, it is an equino-cavo-varus clubfoot. If it is on the lateral side of the foot, a valgus deformity will result, and if this deformity is severe, it will produce the rare "plantar-flexed talus."

Foot Mechanics

Knowledge of the normal motions of the foot is essential to the understanding of these deformities and their correction. It is best to consider the foot as two main units, the forefoot and the rear foot. For practical reasons, the talus (astragalus) should not be considered as forming a part of either unit of the foot. It belongs to the leg from the ankle upward, the talo-tibio-fibula unit, and it forms the base of the platform on which the body weight testers on the unstable movable foot. The talus is held in the ankle mortise and is prohibited from any lateral motion. The only contracture of which it can become a part is dorsiflexion and plantar flexion, a simple anteroposterior motion. All true motions of the foot proper take place below it, in the subtalar joint, or distal to it in the tarsal and metatarsal joints.

The varus and valgus motion is done just below the talus in the subtalar joint, and this is really a rotary motion of the calcaneus under the talus instead of a simple tilting or rocking motion, as we are so often inclined to think it. Thus it is impossible to make a varus heel without rotating the whole foot under the talus. It is equally impossible to make a valgus heel without externally rotating the foot

under the talus. This important point is utilized in the plaster-cast correction of the clubfoot deformities. The correction lies in pulling the foot from one extreme of rotation to an overcorrected position near the opposite extreme of rotation.

The normal motion of the forefoot on the rear foot takes place through the tarsal joints. Although this motion in an adult is comparatively small, in a child the range of excursion is considerable. There is an anteroposterior motion allowing dorsiflexion and plantar flexion, a side-to-side motion allowing forefoot adduction and forefoot abduction, and a rotary motion allowing supination and pronation. These motions take place even though the heel or calcaneus is held fixed and immobile in the examining hand, and the forefoot is said therefore to be adducted or abducted, as the case may be, on the heel. If a contracture occurs on the medial side of the tarsal region, it can cause an adducted forefoot on the heel, with the heel moving freely under the talus into a varus or valgus position. This is the typical metatarsus adductus deformity. With this adduction there is usually some supination, so that the deformity is usually called a metatarsus varus.

Etiology

The etiology of these deformities is difficult to state with any degree of accuracy. Heredity plays some role, particularly in the clubfoot group. Congenital syphilis has been responsible in some of the cases. Browne feels that the deformities can best be explained by a disturbance of the hydrodynamics of the amniotic fluid. He believes that the increased intra-uterine pressure can force the feet of the embryo with such pressure against some part of the child's body that essential changes occur in the tissue at the contact sites. The embryo's feet are bent normally into such positions in the uterus that they simulate the typical deformities which we see at birth. It is entirely possible that excessive pressure can cause what amount to pressure sores at the area of contact, and when these heal the resulting scarring holds the foot in the deformed position. When the feet have been pressed against the skull and face, the indentations are sometimes deep and cause permanent distortion of the areas which received the foot

FIG. 3.

FIG. 4.

Fig. 3. Right foot normal. Left foot is clubfoot, with both forefoot adduction and internal rotation of calcaneus under talus.

ten days. This allows but one wedging to each cast applied. But it is much safer from the standpoint of pressure sores.

When the foot has been swung out far enough into external rotation under the talus, as determined by roentgenogram, the equinus is corrected. To do this the foot is allowed to swing back to neutral position clinically and a new plaster boot is applied, with the talus resting squarely on the calcaneus. If the equinus is corrected with the foot in marked valgus, the talar neck is supported only by the sling ligament (inferior calcaneonavicular ligament) and this ligament may stretch before the talus can be forced into dorsiflexion. This will result in a plantar-flexed talus flat-foot, a difficult complication to correct subsequently.

When the equinus has been removed, a new plaster boot is applied, holding the foot in dorsiflexion and in external rotation under the talus. This is a "retaining" plaster cast. It is changed only when the foot grows and the cast becomes constricting. It is planned to maintain this cast for three months after the date of full correction. This is sufficient time for the contracture to be well stretched out, and for the foot to have grown a little in an overcorrected position. At the end of three months the cast is removed and the mother is instructed how to stretch the foot to its full position of overcorrection, twice daily. This stretching must be done in three ways. (1) To maintain the valgus position, the foot must be externally rotated under the talus

by pressure on the first metatarsal shaft while a countertwisting motion is made by grasping the tibia and fibula. (2) The correction of the forefoot adduction must be maintained by pressure on the first metatarsal shaft and the big toes while counterpressure is made with a grip on the heel, in this manner levering the foot over the calcaneocuboid joint. (3) The correction of the equinus must be maintained by stretching the foot into dorsiflexion with the knee fully extended, since a flexed knee relaxes the gastrocnemius element of the calf.

As soon as the baby is able to walk, "fore-foot abduction" shoes are prescribed. These are shoes which have the distal half of the forefoot in some abduction on the heel. They simply serve to maintain correction of the forefoot, since this is the clinical phase which recurs most quickly. The outer half of the forefoot may have a sole wedge of $\frac{1}{6}$ inch applied by the cobbler, and the outer half of the heel should always be wedged $\frac{3}{16}$ inch for the succeeding three years of life. This wedging tends to maintain the foot swung out into external rotation under the talus, and weight-bearing therefore tends to correct the recurrent tendency with each step the child takes.

2. *Metatarsus Varus*.—The treatment of this deformity is best done with plaster wedgings even in mild cases. This method is easy and sure, and requires much less effort than instructing the mother in manual stretching, only to have the deformity recur as the

inward, but the talocalcaneal position essentially normal, then a metatarsus adductus is present. If the metatarsal bones tend to overlap one another, then there is a supination of the forefoot on the heel to produce a true metatarsus varus. This is always associated with adduction of the metatarsals on the heel.

The salient points to observe in the lateral views are (1) the position of the calcaneus, to give the measure of equinus in a clubfoot, and (2) the position of the talus in valgus flat feet, to determine whether or not a plantar-flexed talus exists. A calcaneovalgus flat foot is easily corrected, but the same foot showing a turned-down talus in the roentgenogram requires special and prolonged treatment.

Treatment

1. *Clubfoot*.—Treatment of foot deformities yields the best results when done as soon as possible after the child is born. At St. Luke's Hospital, we are fortunate in being called to see newborn infants with foot deformities shortly after they are born. I have applied a cast to a baby only five hours old. On the average, however, the first day or two of life is the optimum time to begin correction. Not only is treatment easy then, but the foot has a chance to grow in the corrected position and tends to hold its correction.

The method used on these children is as follows. First, the child's leg, from the toes to mid thigh, is painted with compound tincture of benzoin. This serves two purposes: it protects the skin, and it affords a good sticky base on which the padding is not prone to slip. A thin sheet of felt is cut to encircle the foot and leg as high as the knee. This is held in place with adhesive and maintains its position well on the sticky base of benzoin. Plaster is applied over this felt with the foot held in equinus, and as the plaster hardens the foot is pulled into as much correction as possible. The plaster covers the toes, because the toes are frequently in varus too, and must be swung outward with the forefoot. If the plaster stops short of the toes, an ugly varus toe deformity results after wedgings. On the other hand, by stopping short the level of the plaster below the knee during this stage, one can see how much true correction is obtained through the foot itself. If the plaster is put above the knee at first, one is fooled by the rotation of the tibia on the femur through the knee joint. The foot correction is made by pushing on the medial side of the

FIG. 2. Left clubfoot. Right foot normal. In clubfoot deformity there is forefoot adduction plus rotation of calcaneus under talus.

first metatarsal shaft and head, so that the foot swings into external rotation under the talus. Counterpressure is made on the side of the fibula shaft and not at the ankle. Pressure areas are not apt to develop over such a large flat area as the fibula shaft.

When this plaster hardens the cast is extended up above the flexed knee to the mid-thigh. This causes no strain on the knee. The thigh is included in the plaster because the infant is less likely to kick his feet about and so dislodge the plaster or badly scratch up his other normal foot.

In five days the foot is wedged farther into external rotation under the talus. This is done by cutting a wedge out of the plaster down to the felt and pulling the foot still further into external rotation under the talus. There are several ways of cutting these wedges to swing the foot around. We are very partial to the method of Kite, because it has the advantage of completely correcting the forefoot adduction, and, in so doing, corrects the internal rotation of the foot under the talus. In congenital clubfoot, the forefoot adduction is corrected first. In doing this there is considerable correction of the varus (or internal rotation under the talus) which takes place at the same time. For the foot is so small, and the cast (even a snug one) so loose, that there is considerable play of the correcting force through all the joints below the talus. As a rule, by the time the forefoot adduction has been corrected, the whole foot has rotated considerably under the talus. This rotation must be completed, until, by roentgenographic examination, the desired angle of the talus and calcaneus has been achieved. In the young baby, the foot grows so quickly that a complete change of plaster is indicated usually in

FIG. 7.

FIG. 7. If talus overlaps calcaneus as in right foot, calcaneovalgus foot will develop into severe deformity. Normal relationship is present in left foot.

FIG. 8.

FIG. 8. Baby's calcaneovalgus foot, as in Fig. 7, will develop into this type of foot. This is plantar-flexed talus foot.

tice of the obstetrician's tying a string around the extra toe is not always a good one, unless the toe is a mere nubbin attached by a skin pedicle to the foot. It is better to wait a few days, radiograph the foot, and then excise the toe with a scalpel, being careful not to damage the abductor to the toe. The prognosis in these feet is excellent. The complication to be watched for in after years is the presence of a prominent head of the fifth metatarsal, which can cause trouble by reason of shoe pressure. This may need exostosectomy at a later date.

4. *Hammer Toes*.—In the newborn infant, hammer toe of the second toe is rarely noticed. It tends to become apparent in subsequent months as the child grows. But at birth the contracture is so slight that it is rarely observed. The treatment lies in preventing a permanent contracture from developing.

This is done by stretching the toe to its full range of motion daily. The distal two interphalangeal joints must be stretched to full extension so that they are in a straight line on the proximal phalanx. But the metatarsophalangeal joint must be stretched into full flexion of 90 degrees on the metatarsal shaft. This twice daily stretching of the toe will prevent the formation of a typical hammer-toe contracture, and it does away with the nuisance of constantly applying and fitting splints to the toe. The toe is too small to make splint treatment practical.

The stretching, however, merely prevents a hammer-toe contracture from forming, and it prevents the development of painful dorsal corns from shoe pressure. But it does not cure the underlying muscle imbalance which primarily is responsible. This toe is a constant nuisance as the child becomes older and larger, and surgery is usually indicated at a

later date. The operation of choice is an arthrodesis of the proximal interphalangeal joint in full extension.

The congenital hammer toes of the fifth toes are treated conservatively by the same stretching procedures as are the second toes. They will need surgery at a later age, and the procedure of choice here is a plastic operation and not amputation.

5. *Calcaneovalgus Feet*.—This is most frequently the position in which the child's feet are found at birth. A quick examination will show whether they will passively reduce beyond the neutral position to inversion. If they do this, then no further care is required. Many, however, cannot be placed even in the neutral position. They are held semirigidly in valgus and tend to lie along the lateral surface of the tibia in marked dorsiflexion as well. These should all have roentgenograms to determine one essential point, namely, whether or not the talus is plantar-flexed in the ankle mortise. If the talus is turned downward, then there is present a rare and serious form of congenital calcaneovalgus foot, a "plantar-flexed talus" foot. The child should be placed in the hands of an orthopaedic surgeon, for the treatment will be difficult, long, and tedious. These feet are rarely seen, but they can be helped if properly handled. If left untreated, they develop into a serious deformity which the French call "pied en piolet" or pickax foot. Although the mild type of this deformity can be treated with wedging plaster casts, most cases come to surgery, and some form of surgery should be done early.

If the roentgenograms show that the talus is not plantar-flexed to overlap the calcaneus, then the foot can be easily corrected. The method of choice is to massage and stretch the foot into the equinovarus position. This is

FIG. 5.

FIG. 6.

FIG. 5. Metatarsus varus of right foot. Notice how talocalcaneal angle is normal in presence of severe forefoot adduction.

FIG. 6. Same feet as in Fig. 5 after plaster-cast correction.

baby grows. It is almost impossible to get the mother to stretch the baby's foot hard enough to assure correction. When the doctor assumes the task, the baby cries and the situation is very difficult.

The type of cast applied is the same as that used in the correction of congenital clubfoot. Over a base of felt stuck to the compound tincture of benzoin, the cast is applied with the foot in equinus. This equinus position gives a purchase on the tiny foot. As the plaster is hardening, the forefoot is pushed into abduction, while the counterpressure is applied on the heel. This means that the forefoot is levered into abduction at the level of the calcaneocuboid joint. The foot is not swung out into external rotation under the talus as in the correction of clubfoot. These metatarsus varus feet are already in external rotation under the talus, as the roentgenogram will demonstrate. If anything, they need to be held, not in a valgus heel position, but in a little varus. The cast need extend really only as high as below the knee, but to prevent the baby from scratching his normal foot rather badly on the plaster, it is best to include the midhigh in the cast. This extra immobilization prevents too free a leg motion.

Most of the deformity which is to be corrected is an adduction of the forefoot on the heel, but many of these cases have an associated supination of the forefoot to be removed. It is this forefoot supination, with the adduction, which has given the deformity its name of metatarsus varus. Therefore, when the plaster is hardening, the forefoot is pronated a little on the heel at the same time as it is

carried into abduction to correct the chief deformity.

After the plaster cast has been on the foot for five days, a wedge is cut out at the level of the calcaneocuboid joint. The foot is then pulled still further into forefoot abduction on the heel, and a roll of plaster on top of this maintains the new position.

These feet are usually easily corrected of their adduction deformity. "Retaining" plasters are applied periodically in the succeeding three months' period as the baby outgrows each boot. At the end of three months, the plaster boots are dispensed with, and the mother is instructed how to stretch the foot twice daily into an overcorrected position. This must be done religiously, for there is a great tendency for the adduction deformity to recur as the foot grows. Roentgenograms usually show the returning adduction of the forefoot before it can be observed clinically.

When the child is old enough to walk, it is best to fit the feet with shoes which have an outswung last. These are forefoot abduction shoes of the type used in clubfoot. The main point is, however, not to fit the child with so called "orthopaedic shoes," which have an adducted forefoot on the heel and tend to swing the foot into the very deformity that has been corrected.

3. *Accessory Toes.*—When the baby is born with extra toes, it is necessary to see in the roentgenograms which toe, the fifth or the sixth, is the one that can most readily be excised. Occasionally there is a poorly formed sixth metatarsal and this should be excised together with the accessory toe. The prac-

and when the parents can be relied upon to look after them properly, allow the patient to be taken home after each treatment. However, on the whole we are convinced that better results will be obtained if clubfoot patients are hospitalized. So much for equinovarus.

Other Conditions.—Our treatment of metatarsus varus, hammer toes, and calcaneovalgus so closely coincides with Dr. Thompson's description that comment is unnecessary.

Accessory toes present such odd deformities sometimes that it is impossible to decide which

toe to remove. I believe that radiographs should always be made before deciding what procedure to take, unless, as Dr. Thompson says, the toe is a mere nubbin. Before coming away, I checked over some of these cases of supernumerary toes, and thought that it might be of interest to you to see the slides of a small boy and a small girl who are brother and sister. These slides are interesting because the patients are in the same family, and they also bring out the point that it is easier to know which toe to remove when we have x-ray.

CAUSES OF FEARS IN CHILDREN

Extreme fears in children, shown by sleep-walking, night terrors, nightmares, inability to sleep, and phobias about spiders, cats, and death of one or both parents, can be traced to neurosis and instability in the parents and disturbance in their relationship, Dr. Jacob Kasanin, Dr. Joseph Solomon, and Miss Pearl Axelrod, of Mount Zion Hospital, San Francisco, found in a study of anxiety states in twenty children.

The anxiety state may develop as early as the age of two years. The children in the San Francisco study were between the ages of four and twelve years. None of the mothers could be considered stable, mature women, and many of the fathers were also neurotic.

Both parents and children were treated, and when the parents were able to overcome their anxiety and take a more grown-up attitude toward their problems, the children improved.

When parents were consistent in showing that they did not want children, the latter were less likely to become extremely fearful than when the parents were neurotic and varied between over-devotion and extreme hostility.

More boys than girls were brought to the child guidance clinic for treatment, perhaps because fears in girls are not considered unnatural, whereas when boys are fearful the parents are more likely to be concerned and to seek help for the child. Results of treatment were less satisfactory with the girls than with the boys, probably because none of the girls had a stable father and their mothers were more neurotic than the boys' mothers.

HOSPITALS STOP NIGHT VISITS

Night visiting periods in the twenty-seven municipal hospitals in New York City were abolished on April 14. Dr. Edward M. Bernecker, commissioner of hospitals and director of the Emergency Medical Service, announced that the change would enable hospital staffs to give their full attention to the sick and injured in event of a night raid.

Extensive construction alterations and additions are being made in the city hospitals to protect patients and the staffs from bombs, shrapnel, and machine-gun fire.

Dr. William Jacobs, medical superintendent at Bellevue Hospital, said that a new roof had been placed over the operating rooms in that hospital, and that a reception shelter for the emergency ward is being built of steel and brick and is designed to shield incoming ambulances from shrapnel fragments and machine-gun fire. The shelter is open, front and rear, permitting ambulances to proceed forward after patients have been removed.

Dr. Jacobs said that on some nights as many as 6,000 visitors have come to Bellevue. The presence of such a large number of visitors obviously would handicap arrangements made to handle emergency cases and victims of air-raid bombings. At such times, the entire staff should be able to devote complete attention to the injured and the sick, and not have to consume valuable time in preventing panic among visitors.

The new schedule would not apply to persons desiring to visit patients in a critical condition. Such patients can be visited at any time.

UNITED STATES LOCAL HEALTH SERVICES EXPAND RAPIDLY

There has been a remarkable growth during the past decade in the official establishment of full-time local health services in the United States, a report by the U. S. Public Health Service (Public Health Reports, February 6, 1942) reveals.

On June 30, 1941, a total of 1,669 counties, 54 per cent of the 3,070 counties within the continental U. S., were being served by a full-time public health unit. In 1915 there were only 14 counties in the entire country with full-time local

service. The number of counties thus served had increased to 762 in 1935, and to 1,669 in 1941. Of the latter number 663, or 40 per cent, were served by single-county units; 426, or 25 per cent, by local-district units, and 580, or 35 per cent, by state-district units.

In addition, 103 cities reported full-time municipal health units, which with the 1,669 counties comprise 70 per cent of the total population of the forty-eight states and the District of Columbia.

—*S.C.A.A. News*

done twice daily, from birth, by the nurse. The lower leg is grasped with one hand at the midtibia, and the foot is pulled downward and inward so that it is internally rotated under the talus. The taut tissue over the sinus tarsi is massaged as the foot is being stretched. Most feet will overcorrect to a varus and equinus position within ten days. But the stretching will have to be continued as a rule for three months after this period. In very resistant cases, where there is considerable scarring in the sinus tarsi, plaster wedging casts will have to be applied and the foot held overcorrected for a period of three months in retention plasters. When once corrected, I have never seen one among such feet that required a second series of plaster wedgings. When the child begins to walk, however, the feet may pronate considerably, and the shoes may need inner heel wedges of $\frac{3}{16}$ inch for some time thereafter. But this is of minor consequence, and in general it may be stated that these feet have an excellent prognosis.

Discussion

Charles M. Allaben, M.D., *Binghamton, New York*—It has been a pleasure and a privilege to review Dr. Thompson's paper, and I heartily agree with his management of these cases. One of my difficulties has been to get these babies when they were newborn. To quote from Shakespeare, "there is the rub." In our own immediate locality we do see them early, and at the hospital are notified by the attending obstetrician of deformities in the newborn shortly after birth. Many of our cases, however, come from a rather widespread area, much of it rural. Often, when we eventually see these cases, we are told that the parents have been told that they should wait three months, six months, or a year before attempt is made to correct the deformities. Fortunately, within the last few years, this fallacy is being overcome.

Of the five deformities that Dr. Thompson has dwelt upon, accessory toes may wait perhaps, but the other four conditions should be treated early. It is important to the child's welfare, a saving in time and expense, and better results will be obtained.

Clubfoot.—To me, Dr. Thompson's description of foot mechanics is complete and needs no further explanation. As to etiology, there is one type of clubfoot which I might mention in particular. This is the type often seen in a child with a spina bifida. This has been one of our greatest problems. It has been our experience that correction with plaster is not permanent, and it is now our custom to correct these feet with plaster, hold them as best as we can with braces, and when the child is old enough do a stabilization.

Principles of Correction.—Concerning the principles of correction, Dr. Thompson's and my ideas run parallel. I feel that it bears repeating that the correction of equinus should not be done until the foot has been swung out into external rotation under the talus. It has been my observation that, in the hands of the inexperienced, the failure to do this has been the greatest cause of failure when correction has been attempted.

Roentgenograms.—Roentgenograms are most important. I am convinced that in the past, had we used this method instead of relying on our clinical judgment only, some of our results would have been more satisfactory.

Treatment.—With the exception of a few minor details, our treatment of clubfoot at the Binghamton City Hospital varies very little from Dr. Thompson's procedure. We set aside Tuesday morning of each week for this work, thus using a seven-day interval between casts instead of a five-day period.

Instead of running the cast up over the knee, we place elastoplast bandage around the leg from the bend of the knee and running down 2 or 3 inches, depending on the age and size of the patient. Then, beginning beyond the toes, with narrow sheet wadding, we wind on one layer up to and just over the lower edge of the elastoplast bandage. The plaster boot is then applied extending only to the knee. As stated above, the cast is changed or wedged every seven days. In wedging, we depend upon our judgment in each case. A cast may be wedged two or even three times before it is replaced with a new cast. We always make sure when wedging that the cast is not too tight. When the foot is sufficiently corrected, the final cast is left on several weeks, usually about six weeks.

Before the child leaves the hospital, clubfoot shoes are fitted. For about a year now we have fitted the small babies with outswung prewalker shoes. These shoes have proved very satisfactory—in fact, more so than I had anticipated. They have a metal piece in the sole and a strap which threads through two slits in the shoe, over the foot, close to the ankle. In some cases where clubfoot shoes have not been obtainable, regular shoes were used, the right shoe being put on the left foot and vice versa, thus throwing the forefoot out instead of in.

We have found that one overcorrection is not always a cure. In a series of 54 individual cases treated at the Binghamton City Hospital, 14 had to be corrected again, and 6 of the 14 had to be corrected a third time. It must be understood that most of the cases were older children, not newborn. Neglect on the part of the parents was responsible in some cases, but I am convinced that several of them would have recurred under the best supervision; in two instances, I recall, treatment was started when the patients were newborn. We treat many of our private patients in the office, especially the little ones,

and separated from each other by 3 cm., the two lateral ports being at 15-degree angle to the horizontal, so that all beams begin to converge at about 8-cm. depth. The filter at the skin consists of 1 mm. aluminum, 1 mm. copper, 1 mm. platinum, and 0.5 mm. brass. The x-ray field sizes are 5 by 5 cm. (Fig. 1), 10 by 10 cm. (Fig. 2), and 20 by 20 cm. (Figs. 3 and 4).

It is clearly evident that the shorter x-ray wavelengths deliver a greater dose at any depth beyond 3 to 5 cm., with less lateral scattered radiation. It is also apparent that the 1,000 kilovolt peak x-ray has an advantage over the 3-Gm. radium element pack in that its isodose curves are stronger not only in the center axis but toward the periphery. Thus, the large field treated is more evenly radiated.

The influence of lateral and backscattered radiations is demonstrated in Figs. 5 to 10. At 70-cm. skin target distance, and with a 5 by 5 cm. field size, the 200 kilovolt peak (160 x) x-ray leads in depth dose down to 3 cm., where it becomes weakest of the three qualities. With a 10 by 10 cm. field size, this change occurs at 5-cm. depth. With a 20 by 20 cm. field size, the crossover is in the region of 6 to 8 cm. depth. At 50-cm. skin target distance, comparable results are obtained. We have added depth measurements from the 140 kilovolt peak (285 x) x-ray unit (Figs. 9 and 10).

So far we have compared single fields. To show the influence of quality in routine cross-fire technic, we have plotted depth doses when a urinary bladder is treated with two anterior and two posterior skin ports. In all the figures (Figs. 11, 12, and 13) each half of the pelvis shows doses from a separate radiation quality. However, each dose recorded represents a summation of four fields treated with one x-ray quality. In this way identical sites are better compared. The treatment factors are: skin target distance equals 70-cm.; skin port, 10 by 10 cm. The anterior ports are separated by 4 cm. and are at a 68-degree angle to the horizontal. The posterior ports are separated by 8 cm. and are at a 62-degree angle to the horizontal. The depth percentages indicate the superiority of short-wavelength radiations in delivering greater relative roentgen doses to the depth.

With the shorter wavelengths, the skin ports receive the higher-percentage roentgen dose, owing to the greater penetration or exit dose as demonstrated in all the figures. However, it is clinically evident that the skin shows a greater tolerance for harder roentgen radiations as against similar roentgen doses of longer

wavelengths. This clinical fact has been substantiated by experiments on biologic test material (Packard²).

This, of course, introduces the mechanism of biologic effect. Such details as ion density and corpuscular velocity at any one molecular layer must be primarily influenced by the incident quality. Since the body is a complex collection of vital cell structures, each being closely allied to its neighbor in its function, and dependent on the surrounding tissue mass for nourishment and cellular stimulation, an intelligent interpretation even of biologic effect must necessarily be extremely difficult. Comparisons in all experiments on biologic test material may not necessarily hold true for the human body. Such a phenomenon as selective wavelength effect is most doubtful. It is more plausible that the lethal effect is one of "electron hits" and many of them. By increasing the dose we multiply the number of hits. We might cite the necessity of "concentrated dose" in the treatment of cutaneous basal-cell epitheliomas. We can describe the ability of supervoltage to deliver greater roentgen doses in the depth as due to the greater penetration power of these radiations, albeit of depreciated quality while of relatively increased ion density. The quality of the x-ray beam in the center of the body or at the skin point where it emerges from the body is much softer than the incident beam itself. For this reason much care must be exercised in using supervoltage x-ray on a thin pelvis or other thin anatomic part. The exit dose may be so great and still so altered in quality that any gain in depth dose is canceled by the skin reaction at the opposing port. Here may it be emphasized that with cross firing with supervoltage it is usually impossible to angulate an incident beam so that its exit will not overlap another port and still cover the lymphatics in a proper homogeneous manner.

Clinically, it is rational to compare biologic reactions following treatment with different radiation qualities only when we recognize the facts that each effective wavelength is an instrument in itself and may vary from another effective wavelength in its tissue activity.

No source of radiation is of any value to a patient unless it is used properly. Here it is most pertinent to stress the importance of the radiologist. He is really a surgeon who substitutes a powerful radiation instrument for a scalpel. There is no reason why even greater improvement cannot be achieved with low- or medium-voltage apparatus. The skill of the

THE CLINICAL AND PHYSICAL SIGNIFICANCE OF QUALITY IN ROUTINE TELERADIATION THERAPY

WALTER T. MURPHY, M.D., Buffalo, New York

THE quality of the primary radiation beam determines its course and behavior in the tissue. In therapy, the spectral distribution of the radiation is heterogeneous, ranging from a minimum wavelength to a maximum wavelength. The greatest concentration of rays is near the short-wave end of the spectrum. The minimum wavelength is determined by the voltage, whereas the total spectral distribution is governed by filter as well as voltage.

When a thimble ionization chamber is placed in the path of this radiation beam, only the amount of ionization which takes place in the chamber is recorded. This holds true with the gamma radiation from the radium element packs. It is conceded that calibrations of supervoltage and radium radiations by the thimble ionization chamber are open to criticism. Thus we measure only that portion of the total energy carried by the beam which has been removed or utilized in that specific volume of air.

But we are primarily interested in the behavior of the beam when and after it reaches the tissue. Again, any measurement of intensity at the skin or in the depth represents only the amount of ionization taking place in the particular volume. Since the biologic effect is directly or indirectly due to this ionization, it seems pertinent to review the chain of events in the life of the primary photon.

It is difficult to describe in exact terms what happens in the tissue, because of many problems of quality measurement. The thimble ionization chamber alone does not define the wavelength or corpuscular velocity. But we may briefly state that the primary photon loses all or part of its energy in proportion to its initial energy. If it is of low energy (long wavelength), all or almost all of the energy is transferred to secondary beta particles, while the rest emerges as photons of much lower energy. If the primary photon is of high energy (short wavelength), less of the energy is transferred to secondary beta particles, while the remainder is carried by the photon itself, following the law of Compton effect. Of course, there are intermediate degrees of

interchange between photoelectric and Compton effects. All the photons and electrons so resulting carry out an almost endless interchange of energy. But the resultant lower-energy photons and electrons transverse shorter paths. We may therefore state that in the softer x-ray spectrum the photoelectric effect predominates, with the maximum energy interchange taking place in the first layers of tissue. With hard x-ray and gamma radiation, the Compton effect predominates, with the maximum energy interchange occurring deeper in the tissue. As the radiation beam goes deeper, the increase in the number of photons traveling in the lateral and backward directions has been described by Failla¹ as comprising "those which have been produced through photoelectric and Compton energy interchanges (largely the latter), and those primary photons which have been scattered without loss of energy."

For any one quality, the field size and skin target distance are of great importance. With longer wavelengths the field size exerts a greater effect on the depth dose. The harder our therapeutic beam, the greater our depth dose, with a relative decrease in the lateral and backscattered radiation outside the main beam. We shall now compare the influence of different qualities on tissue dose when field size and skin target distance remain constant.

Calibration of the radiation equipment was made by the Physics Department with a Victoreen thimble chamber and press wood phantoms. The isodose curves were then applied to a serial section of the female pelvis at the level of the middle of the acetabulum. The anteroposterior diameter is 20 cm. All dose recordings are in percentages of the measurements on the surface with backscatter. Only one-half of the radiation beam is recorded on the charts, in order that the different radiation qualities may be more clearly compared.

In Figs. 1, 2, 3, and 4 we have compared the depth doses of 200 (160 x), 400 kilovolt peak (50 x), and 1,000 kilovolt peak (27 x) x-rays, and 3-Gm. radium element pack (gamma). The x-rays were applied from a skin target distance of 70 cm. The radium pack (Fig. 4) factors are skin radiation distance of 10 cm., and three ports each containing 1 Gm. of radium; the ports are each 5.4 cm. by 9.3 cm.,

radiologist is more important than the limitations of his radiation equipment.

Because of certain physical factors already mentioned, we have no right to compare skin reactions without first evaluating the quality of the primary radiation beam, the degree of electronic equilibrium in the skin, the amount of backscattered radiation (as influenced by field size and quality), the exit dose with its depreciated quality, the cycle or technic of treatment—which includes the roentgen rate per minute—the increment dose, the total roentgen dose to each skin port, and the time (days) over which the treatments have been applied. Therefore, it is obvious that the reaction in the depth would also be governed by these factors.

Clinically, it is possible in our routine practice to deliver far greater roentgen doses in the depth when we use the 1,000 kilovolt peak (27 x) and 400 kilovolt peak (50 x) apparatus. Our 3-Gm. radium element pack requires at least 40 per cent more treatment days to deliver a comparable roentgen dose in the depth.

In spite of any argument that the tissue in the depth should exhibit the same relative roentgen tolerance as the skin, the vaginal mucous membrane has shown much greater reactions following supervoltage radiation (27 x) than following 200 kilovolt peak radiation (160 x), when the skin reactions were biologically similar. With supervoltage (27 x) x-ray radiation the biologic dose may be 80 per cent of the measured roentgen dose, whereas with 200 kilovolt peak (160 x) x-ray radiation the biologic and physical doses may be equal. Nevertheless, the greater roentgen doses delivered in the depth by supervoltage radiation more than offset such a ratio (4 to 5). This relationship in the skin might not hold true for

Because the radiation beam from the 1,000 kilovolt peak (27 x) x-ray unit is so well de-

fined, it is possible to cross-fire more accurately with smaller fields when indicated. This diminished lateral and backscattered radiation outside the main beam accounts partly for the well-being of the patient during therapy. We

are not sure whether the greater roentgen doses delivered by the 1,000 kilovolt peak (27 x) x-ray unit will result in more five-year cures. We do know that the immediate results are more promising and that the patient's general tolerance is much better than with the longer-wavelength radiations.

Conclusions

1. The skin dose and depth dose are influenced by the quality of the primary radiation beam if other treatment factors remain constant.

2. The harder the quality, the less intense are the lateral and backscattered radiation. Thus the 1,000 kilovolt peak (27 x) radiation beam may be applied more accurately because of this confined ionization at depth.

3. Supervoltage (1,000 kilovolt peak) radiation is of distinct advantage only in deep-seated lesions.

4. For the same number of roentgens the tissue reaction as manifested by the skin erythema is less with 400 kilovolt peak (50 x), 1,000 kilovolt peak (27 x), and gamma (3-Gm. radium pack) radiations than with 200 kilovolt peak (160 x) or 140 kilovolt peak (285 x) radiations. Even though the biologic dose of supervoltage radiation may be less than the measured physical dose (e.g., 4 to 5), its power

to deliver large roentgen doses in the depth more than offsets such a ratio.

5. Patients tolerate treatment with supervoltage (27 x) and gamma radiation better than with low-voltage (285 x and 160 x) or medium-voltage (50 x) radiation.

6. With present technic, the 3-Gm. radium element pack requires 40 per cent more treatment days to deliver comparable depth roentgen doses than the 1,000 kilovolt peak x-ray unit.

7. The skill of the radiologist is more important than the limitations of his physical equipment.

8. Improved technic with low- and medium-voltage apparatus (140 to 400 kilovolt peak), when combined with a greater knowledge of both clinical and experimental biologic-physical reactions, will certainly increase immediate and late palliations and cures.

9. This knowledge, as applied with the newer radiation equipment, invites great optimism for the increased value of radiation therapy. Therefore, we may entertain a better prognosis for the cancer patient.

IMPORTANCE OF HOSPITAL RECORDS

Personally, I have been somewhat surprised by the extent to which doctors leave the making of hospital records to nurses. Thereby, it seems to me, the history is too much opened to error, especially of omission. As evidence, the chart will have probative value largely in proportion as it speaks for the doctor rather than the nurse.

The suggestion is, not that you should do the writing, but only that, as a matter of self-interest, the record is important to you. It is apt to be highly so if fate ever casts you for the part of defendant in a malpractice suit.—ROYAL STONE, Supreme Court of Minnesota, February 22, 1941.—*Clinical Medicine*

SECURITY NEEDED BY ALL

Emotional starvation is just as real as physical starvation. In order to grow emotionally, an individual must feel that he is a worthwhile person, that he is needed somewhere by someone, that there is a place for him in his family group, in his social group, in a vocation, and in the world. He must have, permeating all that he is and does, the certainty that he can confidently look himself and other people in the face. Then he knows security. Superficial observers describe it as self-confidence or self-respect. An individual with security might describe it as the background against which his life is lived.—J.A.M.A.

Friend: "I don't like to say it, dear, but Fred doesn't seem to be as well dressed as when you married him three years ago."

Doctor's Wife: "That's strange. I'm positive it's the same suit."—*The Doctor and Old Quarterly*

POLYPS OF THE RECTUM AND COLON

Their Etiology, Clinical Significance, and Treatment

JOHN C. M. BRUST, M.D., Syracuse, New York

THE earliest recognition of polyps of the rectum dates back hundreds of years. Countless case reports can be found describing prolapsing polyps which received all varieties of treatment. During the past ten or fifteen years a considerable amount of clinicopathologic work has been performed and reported. In all justice it must be said that many of these clinical reports have been repetitious and that many of the conclusions have been unsupported by pathologic studies.

It appears impractical to quote at any length from the literature other than to pay tribute to the painstaking, detailed studies of such men as Dukes, Hullsick, Swinton and Warren, David, Lockhart-Mummery, and others.

At this point, let me summarize what I believe to be the present-day opinion regarding adenomas of the rectum and colon.

1. They are more common in men than in women, and the ratio 3 to 2 is identical with that of carcinomas of the same portion of the intestinal tract.

2. The average age in any large series will be about 46 years and this is about one decade younger than the occurrence of carcinoma.

3. The anatomic location of these polyps closely parallels that of cancer.

4. Symptoms are not characteristic but, if present, merely point to the need for complete sigmoidoscopic examination followed, if indicated, by a roentgenogram of the colon.

5. Polyps measuring less than 1 cm. in diameter rarely produce symptoms.

6. It is difficult and dangerous to state from gross appearance that a polyp is or is not undergoing malignant change.

7. Malignant change in a polyp tends at first to be localized at the periphery and might easily be missed in removing a biopsy specimen.

8. Eradication of polyps of the rectum and sigmoid can, in practically all instances, be accomplished by means of the unipolar fulgurating electrode.

9. The chances of a polyp becoming malignant are too great to allow the physician to regard the condition as unimportant.

10. Present-day evidence points to the apparently benign polyp as the origin of many and perhaps most of the carcinomas of the rectum and colon (Fig. 1).

During a five-year period from January, 1936, to January, 1941, I have done complete sigmoidoscopic examinations on 2,146 private patients and have found polyps in 123 of them. During these same years in the wards and outpatient departments of Syracuse University hospitals, 1,852 charity patients were examined with a sigmoidoscope either by me or under my supervision. The patients in whom polyps were found numbered 89. Pooling these data, we find that in approximately 4,000 persons carefully examined with a sigmoidoscope after cleansing enemas an adenoma, either benign or beginning to undergo malignant change, was found in a little more than 5 per cent of the patients. These figures do not include persons suffering from hereditary multiple polypoid disease, nor do they include multiple polyps or pseudopolyps that were clearly on an inflammatory basis, such as chronic ulcerative colitis.

My purpose is by no means to offer statistics. Rather I intend to present a few different types of problems that we have encountered in this field, to discuss our therapeutic attack, and, above all, to ask for advice and criticism.

The small polyp rarely produces symptoms, is usually discovered accidentally, and is easily destroyed by fulguration. It is a simple office procedure. However, I can do nothing but condemn the casual habit of destroying the polyp and lightly brushing the matter aside without a word of warning to the patient. Such a person should be seen for a recheck sigmoidoscopic examination. The following history demonstrates this fact with startling clarity.

Case Report

Case 1.—This patient, a woman, aged 46, was first seen by me in early October, 1937. The history was of long-standing symptoms of gas, periodic constipation, and passage of mucus. Curiously enough, in 1927 a small benign rectal polyp had been accidentally discovered by her obstetrician. This was excised from the lower anterior rectal wall. No recheck had ever been done. For about one year prior to my seeing her

FIG. 1. Polyp of transverse colon discovered at autopsy with carcinomatous degeneration at the tip.

she had noticed a vague sense of pressure in the rectum and increased passage of mucus. A rare streak of blood was casually mentioned.

Sigmoidoscopic examination revealed a flat polypoid mass on the right rectal wall. Area involved measured about 4 by 3 cm. The area was soft, velvety, and freely movable and felt like a thin layer of moss. The patient was admitted to the hospital where it was felt that under a sacral block anesthetic a better exposure could be obtained. A biopsy was taken and fulguration was begun. Anesthesia being complete, the anus was widely dilated, an N. D. Smith speculum inserted, and a splendid exposure obtained. A specimen was taken for biopsy and was reported as benign adenoma (Fig. 2). The entire area was extensively fulgurated, using the Oudin monopolar current, a short pistol length fulgurating handle and tip.

No postoperative bleeding occurred, and eight days later the entire procedure was repeated. This time to our dismay the pathologic report was low-grade adenocarcinoma in an adenoma (Fig. 3). Further fulguration was performed and it was felt that all of the tissue had been destroyed.

In my office one month later she was rechecked, and a tiny elevated area was destroyed by fulguration. Three months later a similar area just inside the sphincter was destroyed by fulguration. During this time both the patient and her husband, who incidentally were people of high intelligence, were aware of the significance of our findings. We had emphasized that radical resection might be needed. The patient herself had flatly refused. Consequently, she was checked every month or two and frequently small elevated polypoid areas were fulgurated. In August, 1938—ten months after being first treated—a small area was found so low down that it was felt that fulguration could not be done without anesthesia due to burning of

the anus. Consequently, she was readmitted to the hospital, sacral block was administered, and the area was deeply fulgurated. (I cannot refrain from mentioning how much more satisfactory the exposure is following block anesthesia. This is particularly true in these flat "mossy" adenomatous growths that are easily missed if the sphincter is not relaxed.) In any event, biopsy taken again showed low-grade adenocarcinoma in an adenoma.

This woman has been rechecked every month or two and for a period of over twenty-eight months no polypoid tissue has been seen. Naturally, we are highly gratified but certain qualms arise. Have metastases already occurred? It hardly seems likely. She is a picture of health and feels wonderfully well. Will recurrence take place? This I cannot tell, but she will be re-examined from time to time. Should radium also have been used? I felt that radium would have helped had the danger of hemorrhage been present, but I believe it is true that adenocarcinoma of such a low grade is practically radio-resistant.

Many of the standard textbooks of the day teach that polyps of the colon and rectum are usually found in children. Certainly this has not been true in my own experience. I have seen but 18 polyps in children in private practice over a period of nearly six years. When these are encountered, certain minor difficulties arise. General anesthesia is usually required and, if the polyp is quite high up—that is, above the peritoneal reflection—great caution must be exercised. Breathing under general anesthesia is deep, and the sigmoid with its polyp moves up and down in an exasperating manner. But, if a small-tipped electrode is used, if the power is kept down, and if the polyp is burned beginning at the periphery, complete eradication is possible. However, it may be necessary to repeat such procedures.

Case Reports

Case 2.—One rather nerve-racking experience stands out clearly. A young girl, aged 7, was brought in by her mother, who ironically was a nurse. The child had been bleeding for six months. Examination in the office was only for about 14 cm. from the anus because of the lack of cooperation from the child. No lesion was seen. Barium enema with double contrast technic revealed a fairly large pedunculated polyp in the middle sigmoid (Figs. 4 and 5).

The mother was opposed to the abdominal approach, so with great misgivings I did the sigmoidoscopic examination and fulguration under a careful and expert general anesthetic. Recheck of the sigmoid again under anesthesia one month later showed a faint gray scar at the

Fig. 3.

Fig. 3. Subsequent biopsy specimen from Case 1—adenocarcinoma.

site of the polyp. Incidentally, biopsy, taken before fulguration was started, revealed benign adenoma.

Case 3.—A comparable case, though at the other extreme of age, was a woman aged 69, who had been bleeding off and on for about ten years. Previous roentgenographic studies of the colon had failed to reveal any lesion. Sigmoidoscopic examination revealed a polyp on a broad pedicle. The pedicle was about 2 cm. long and the polyp was roughly 4 by 5 cm. in size. The growth was 23 cm. from the dentate line. Here was a difficult problem to meet. The woman was in poor physical condition, with hypertension and a mild diabetes. Her hemoglobin measured only 54 per cent. After long discussion she decided to "gamble" on fulguration rather than laparotomy. It was explained to her that numerous fulgurations would be required, that the risk of hemorrhage existed and might be profuse, and that although the original biopsy showed benign adenoma we could not be certain that carcinoma did not exist. All this she conceded and so we went ahead. She visited the office a total of fourteen times and sixteen months following the last fulguration there was no evidence of any neoplasm. Needless to say frequent rechecks will be needed (Figs. 6 and 7).

I should like to interject my personal views as to the value of the electric wire snare as opposed to the rounded electrode tip. I was beguiled two years ago into purchasing one of the wire snares with the electric connection whereby the loop introduced through the proctoscope or sigmoidoscope is slipped around the pedicle of the tumor, the snare is tightened, and at the same time the current is turned on by a foot switch. The theory seemed good but in actual practice I have had two alarming hemorrhages within twenty hours of the snare excision. I believe it is

better to fulgurate slowly from the periphery of the tumor. It is a large polyp that requires more than one or two attempts and in any event a repeated fulguration is far preferable to the panic that accompanies profuse hemorrhage. Again, I should appreciate advice from those who have tried both methods.

When is hospitalization desirable or necessary? Certainly, in polypoid areas involving the lower rectum, profound relaxation of the sphincter is needed and transsacral or low spinal anesthesia will accomplish this. Where the polyp is well above the peritoneal reflection and exposure is not always easy it is probably best to do the work in the hospital.

Fulguration of adenomas results in a slough and this slough comes away usually about the eighth to the tenth day. At this time bleeding may occur and in rare instances is occasionally alarming. By being content to fulgurate the larger polyps in "piecemeal" fashion I have been fortunate so far in avoiding any serious bleeding.

Should the area being fulgurated appear extremely vascular I am entirely in accord with Dr. Buie, who advocates the immediate placing of radium against the fulgurated area. This is done less to destroy the tumor tissue than to "provide additional insurance against hemorrhage."

As to the actual technic of fulguration certain prerequisites appear outstanding. True, "one man's meat is another's poison," but I would be at a loss without a suction sigmoidoscope or a combined fulgurating suction electrode. I could not do good work without careful cleansing enemas. I need an assistant who is trained. Above all I need an in-

FIG. 7.

FIG. 7. Another specimen from Case 3—low-grade adenocarcinoma.

survey of rectal polyps observed during the past ten years. We, too, have found these polyps to be more common in men in the ratio of 3 to 2.

With regard to age, we found about 27 per cent occurring in the first decade of life, and about 22 per cent occurring between the ages of 40 and 50. The other cases averaged about 10 per cent in each decade up to 70 years.

While bleeding is the chief symptom which brings the patient to the doctor, bleeding, as in Dr. Brust's experience, is not always caused by the polyp but by other concomitant pathology, usually hemorrhoids, and the polyp is not infrequently found incidental to proctoscopic examination.

I feel, as Dr. Brust does, that every colonic polyp left untreated is a potential cancer. It is an established fact that malignant changes do take place in polyps of the colon and rectum; and, therefore, although these polyps may not be actually classified as malignant tumors, they must be treated as if they were such and must be completely destroyed when discovered.

It stands to reason, as Dr. Brust has told us, that every polyp removed should be carefully examined by a tumor pathologist for malignant changes. Also, all these cases should have a complete contrast enema x-ray study of the whole colon to eliminate the possibility of lesions higher up. Of course, we cannot depend on the x-rays to reveal the small sessile polyps.

Quite often, a small malignant polyp of the lower sigmoid or rectum may be a transplant of a more extensive lesion higher up in the colon. In such cases the x-ray studies will be of great value. Dr. Brust considers the treatment an office procedure. We prefer to treat these cases in the hospital, especially considering that most polyps are above the peritoneal level.

Dr. Brust objects to the electric snare and uses the unipolar fulgurating electrode instead. That

is a matter of preference. Of course, where the polyp is small and is without a pedicle, the small electrode tip is the instrument of choice. But where the polyp has a pedicle and is of some size, excellent results can be obtained with the electric snare. In our series 75 per cent of the polyps were removed with the snare. There is little danger of bleeding with the use of the snare, provided that the coagulating current and not the cutting current is used. Should there be some bleeding after snaring the polyp, the tip of the snare can be effectively used to coagulate the bleeding point. A potential danger does exist, however, in the use of the snare—perforation of the bowel wall. However, as in all other methods of surgical treatment, it is the technic and skill of the operator that determine the instrument to be used. We have successfully used the snare in removing large polyps with a base as broad as 4 cm.

In our series we had pathologic reports on 56 specimens of rectal and sigmoidal polyps. Of these, 50 were reported as benign; 5, as grade 1 malignancy; and 1 as grade 3 malignancy. The patient with the grade 3 malignancy was later found to have a large obstructing carcinomatous lesion of the pelvic colon. One of the patients with a grade 1 malignancy had a recurrence seventeen months later which had developed into an extensive carcinoma.

In conclusion, may I reiterate with Dr. Brust that

1. Every rectal or colonic polyp that is accessible should be thoroughly removed, for carcinoma is apt to follow at some future time.

2. Whenever the pathologic report of a polyp returns with a diagnosis of malignancy, a complete x-ray study of the colon should be made to rule out a malignant lesion higher up.

3. Every case of colonic polyps should have a periodic check-up for recurrence.

FIG. 4.

FIG. 4. Roentgenogram following barium enema on Case 2 showing no apparent lesion.

FIG. 5.

FIG. 5. Roentgenogram on Case 2 with double contrast technic revealing polyp of sigmoid.

verted table. These procedures occasionally take long periods of time, and most patients cannot be adequately treated in the knee-chest position, and I have neither the dexterity nor the strength to do this work in the Sims position.

The decision as to the treatment of a polyp in the colon above the reach of any sigmoidoscope constitutes a difficult problem. I believe that, if possible, every individual in whose rectum or sigmoid is found a polyp or polyps should have a most detailed roentgenographic examination of the colon. Certainly, the technic of double contrast as originated by Fischer has been a tremendous advance. I hesitate to state that whenever a polyp is found in the upper colon it should be removed by means of colotomy. If it is actively bleeding, by all means, yes. If it is of fair size—that is, over 2 cm. in diameter—again, yes. If the polyp is felt to be growing on repeated roentgenographic examinations, certainly. But to open a person's abdomen and colon for a small polyp that was rather accidentally discovered requires some courage. I believe such patients should be instructed as to the significance of the lesion and urgently advised to be re-examined within two months at the

most. It has been shown that many polyps benign in character may be present for years without producing symptoms and without apparently growing in size.

The answer to many of these questions rests in the last analysis with the trained pathologist. With increasing experience is said to come greater conservatism. Certainly, I never ignore pathologic findings, and yet I find myself more and more willing to undertake the destruction of extensive polypoid areas and polyps high in the sigmoid. It is true, however, that a definite middle-of-the-road course must be steered.

614 Medical Arts Building

Discussion

Dr. Alfred M. Buda, Brooklyn—Dr. Brust has given us an excellent résumé of the present-day concept of solitary polyps of the colon and rectum. He has presented his experience in treating this disease and has formulated some conclusions resulting from his five-year survey.

Those of us who do similar work will agree with practically all that Dr. Brust has said. However, different experiences in other hospitals will modify somewhat the opinions expressed by Dr. Brust.

At the Brooklyn Hospital we have made a

to have received arsphenamine just prior to the onset of symptoms. After a prolonged course in which all findings were those of aplastic anemia, the patient died with a terminal picture of leukemia, and we have no proof that the exposure to benzol had any relation to the disorder.

In addition to the difficulties instanced above, studies of clinical symptoms, signs, blood changes, and tissue findings have not revealed any significant characteristics that serve to differentiate the cryptogenic from the secondary cases even when other criteria are most decisive.

Symptoms and Signs

Presenting symptoms, enumerated in order of the frequency of their occurrence, were as follows: bleeding, weakness and fatigue, dyspnea, febrile reactions (colds, flu, grippe, chills and fever), dental symptoms, anorexia and loss of weight, pains, aches, and paresthesiae, edema of ankles and face, gastrointestinal symptoms not related to bleeding (nausea, vomiting, diarrhea and abdominal distress), soreness or ulceration of mucous membrane surfaces, blurring of vision, head symptoms (pounding, tinnitus, fainting, dizziness and headache), palpitation, pallor, joint pains or swelling, drowsiness, paralysis, reactions to medications, jaundice, glandular swelling, and nocturia.

Abnormalities noted in physical examination, enumerated similarly, were as follows: pallor, purpura, fever, systolic murmur, enlarged lymph nodes, abnormal neurologic signs, ulcers of mouth or throat, yellowish discoloration of the skin, mucous membrane bleeding, retinal hemorrhage, abnormal pulmonary signs, enlargement of the spleen, edema, enlargement of the liver, abnormal heart signs other than systolic murmur, abscess, tenderness of the sternum, atrophy of the tongue, stupor, and abdominal tenderness.

In the main, the clinical symptoms and signs presented by this series of cases are similar to those usually described. One exception must be noted, however. Rosenthal⁴ has stated that lymph nodes, liver, and spleen are not enlarged in aplastic anemia. In the present series of cases approximately 34 per cent of the patients had some degree of enlargement of lymph nodes clinically; 15 per cent had both lymph node and spleen enlargement; and 12 per cent had enlargement of lymph nodes, spleen, and liver. These clinical observations were substantiated by necropsy findings, as will be seen in Table 5.

Blood Picture

Twenty-five of the cases gave classical findings of severe anemia, leukopenia, and thrombocytopenia. Six showed anemia and leukopenia with but slight changes in thrombocyte levels. Two showed profound anemia only, and one showed anemia and thrombocytopenia with slight, but definite, leukocytosis. The anemia was of the macrocytic type in 27 per cent of the cases, normocytic in 54 per cent, and microcytic in 19 per cent.

Gastric analyses were made in 13 cases. Only one of these showed achlorhydria, and this was a patient having macrocytic anemia. Six other patients with macrocytic anemia showed normal gastric contents.

Evidence of erythrocyte regeneration was almost uniformly less than is found in similar grades of anemia of other kinds. Reticulocyte percentages varied from 0 to 2.8. They exceeded 1 in only 14 per cent of the cases. A rough correlation of the various signs of regeneration is shown in Table 2.

TABLE 2.—ERYTHROCYTE REGENERATION

	Percentage
Anisocytosis and poikilocytosis only	19
Anisocytosis, poikilocytosis, polychromatophilia, and reticulocytes less than 1 per cent	47.6
Anisocytosis, poikilocytosis, polychromatophilia, and reticulocytes more than 1 per cent	23.8
Anisocytosis, poikilocytosis, polychromatophilia, reticulocytes of variable percentage, and nucleated red cells	9.5

Systematic studies of evidence of blood destruction were not made. Serum bilirubin exceeded 0.5 mg. per hundred cubic centimeters in but one of the 18 cases in which it was estimated. Urobilinogen did not exceed the concentration represented by a positive Wallace and Diamond test of a 1 to 10 dilution in any of the 13 cases. Fragility tests in 6 cases showed normal results.

Leukocyte counts were less than 1,000 in 4 per cent of the cases; between 1,000 and 2,000 in 30 per cent; between 2,000 and 3,000 in 36 per cent; between 3,000 and 4,000 in 20 per cent; and above 4,000 in 10 per cent.

Differential counts characteristically showed deficits in all types of cells. In terms of percentage figures the majority showed lymphocytosis. However, an absolute increase in the concentration of lymphocytes was noted in only 2 cases. In 5 others the lymphocytes were within normal limits. In the remainder they varied from 1,800 to 160. Mature neutrophils were even more strikingly reduced in number. In only one case was the count normal. In the

APLASTIC ANEMIA

STUART L. VAUGHAN, M.D., Buffalo, New York

THE term "aplastic anemia" as used at the present time is susceptible of various interpretations. In a recent discussion Rosenthal¹ has considered the disorder as a progressive condition of unknown cause characterized by severe anemia, leukopenia, thrombocytopenia, and acellular bone marrow. According to this description, the diagnosis is reserved exclusively for those cryptogenic cases presenting typical findings. Cryptogenic cases not conforming to this picture are segregated as atypical, and cases in which the cause can be ascertained are likewise segregated as secondary. Rhoads and Miller² have tended to broaden the use of the term considerably and to eliminate some of the need for segregation, by including in one general category cases that were regarded as fundamentally similar in nature although differing in bone marrow cellularity and occasionally in other features.

The present paper deals with 34 cases in which the findings before or after death, or both, were interpreted as those of aplastic anemia in the broader sense indicated above. Most of these were of the cryptogenic type, but secondary cases are included also. Additional cases in which some other disorder was found to masquerade as aplastic anemia are cited to illustrate diagnostic difficulties.

Etiologic Factors

The age varied from 10 months to 75 years. Only 38 per cent of the cases were under 30 years of age. This finding is at variance with the statement of Rosenthal,¹ who says that the disorder "usually occurs in individuals under 30 years of age." However, a greater proportion of cryptogenic than of secondary cases fell in the younger age group. The ratio of males to females was about equal (1.1 to 1). There was an interesting age-sex relationship (Table 1). In the age period under 50, females predominated, while in that after 50 the reverse was true.

TABLE 1.—AGE-SEX RELATIONSHIP

	Males	Females
Before puberty	2	3
Puberty to age 50	7	11
After age 50	9	2

Study of ethnic factors revealed that the disorder was partial to no special group in the community. Thirty-two subjects belonged to the white race and 2 to the Negro. Among those of white race, 12 were of British, 7 of Germanic, 5 of Polish, 5 of Italian, 2 of Jewish, and 1 of Hungarian descent.

Occupations were as follows: housewives, 10; students, 5; physicians, 2; laborer, painter, oiler, tailor, brewer, dancer, merchant, demonstrator, customs officer, lithograph artist, musician, carpenter, and farmer, 1 each; unknown or none, 4.

Of this series, 10 cases were quite definitely of the secondary type, with arsphenamine ascribed as the cause in 6 of them, and benzol in 4. The remaining 24 cases were regarded as cryptogenic, although two of the patients seemed to have toxemia of pregnancy at the onset, and one showed miliary tuberculosis terminally.

The importance of attempting to classify cases as cryptogenic or secondary is obvious for the purposes of enhancing our knowledge of underlying processes, recognizing therapeutic, industrial, and other hazards, and to some extent indicating prognosis and treatment. On the other hand, experience in the present study has led to the conclusion that such classification is by no means simple. In the first place, adequate means for making a clear-cut differentiation between the two classes are lacking. As is usually the case, the history is the deciding factor. When a history of exposure to one of the known injurious agents is elicited, the case is classed as secondary, and vice versa. How often such exposure is purely incidental or is merely the trigger mechanism setting off a latent constitutional defect, and how often we fail to elicit a history of exposure that may have been causative, are questions difficult to answer.

Some of these difficulties were encountered in this series. Patient E. K.,³ listed as a secondary case, gave a history of frequently using a shoe cleaner containing benzol. While work in industrial benzol poisoning⁴ has revealed that rather minimal exposure may at times result in severe anemia, we have no accurate knowledge as to whether the exposure in this case was truly causative or not. Also, patient E. D., described by the author and collaborators in a previous paper,⁴ was known

majority of these elements were relatively small cells resembling lymphocytes. Scattered myeloblasts, myelocytes, and young nucleated red cells, usually of small size, were present. There was a noteworthy absence of myeloid cells of greater maturity than the myelocyte, and of more nearly mature normoblasts. The marrow picture presented by these cases is quite similar to that described as characteristic of aplastic anemia by many authors, and to the group of cases described by Rhoads and Miller² as "aplastic anemia with aplastic marrow" (Fig. 1A).

Eight cases showed much greater degrees of cellularity than the ones just described. For various reasons it has seemed impractical to do more than roughly estimate the cellularity. In the first place, marrow of normal subjects varies considerably in this respect, and without more accurate methods than now exist the estimate is purely a matter of judgment. Of ever greater importance is the observation that the marrow in these cases varies greatly in sections obtained from different regions. Even in the same section these cases have tended to show marked variations, with areas of increased cellularity alternating with others in which cells are greatly reduced in number.

In 2 cases (L. W. and S. R.) there seemed to be a distinct general hyperplasia (Fig. 1D), and in one (L. B.) a hypoplasia which did not reach the proportions of those relatively acellular marrows previously described. In the remainder, the degree of cellularity could not be estimated with any certainty, although the impression gained was that it was normal (Fig. 1B) or increased. The picture in some of these marrows was quite characteristic. Areas of relatively acellular marrow alternated in an entirely irregular fashion with larger and smaller areas of normal cellularity or of actual hyperplasia (Fig. 1C). The hyperplastic areas differed from one another markedly, some showing a predominance of myeloid elements, and others showing a more pronounced erythropoiesis. In each case the practically complete absence of mature nucleated cells was conspicuous. Lymphoid cells were seen in all of these cases, and, while they were more noticeable in hypoplastic areas, it was not felt that absolute increases were present. Megakaryocytes were absent or difficult to find. Plasma cell types were few and variable. Mitotic figures were more numerous in some cases than in others. In one of the cases (J. P.) the finding in the trephine specimen of a pre-

rest they varied from 2,400 to 20. The majority of cases showed a rather marked disproportion between filament and nonfilament cells, with the latter relatively increased. Arneith indices were greatly increased. It is clear, however, that this apparent left shift is more the result of reduction in the number of filament cells than of increase in nonfilament forms. In 15 cases, juvenile cells were encountered in small numbers; and in 7 of these, myelocytes were seen also. However, only one (L. W.) showed these cells in what seemed to be significant numbers. In this case the count was as follows: immature myeloid cells, 1,000; mature myeloid cells, 120; lymphocytes, 1,600. This finding led to considerable confusion in diagnosis. Monocytes exceeded the normal in one case (J. P.) with 2,300, which finding also caused diagnostic difficulties. The remaining cases showed monocyte counts varying from 750 to 0.

Platelets were reduced in number in 94 per cent of the cases. In 82 per cent the counts were below the "critical" level of 60,000. In 2 cases they were above 200,000. It is interesting to note that all cases but one having counts below 60,000 showed bleeding symptoms, and that 2 cases with counts well above

this level showed abnormal bleeding in mild degree.

Bone Marrow

Bone marrow has been examined in 26 of the 34 cases. Marrow specimens were obtained either during life, or at postmortem examination, or both. Those taken during life were sternal biopsy specimens of either the aspiration or trephine types. Those taken postmortem were from various bones, such as sternum, rib, vertebra, and femur. While no available specimens were ignored, the ones taken from the sternum have served as the basis for study for the sake of comparison with biopsy material. In 12 cases more than one type of examination was made, and in a few instances biopsies were repeated at varying intervals.

Tissue sections from 20 cases were examined. The usual technic consisted of fixation in Zenker formalin solution, decalcification, and staining of sections with a combination of Giemsa's and Wright's stains.

Twelve of the cases showed remarkable reduction in marrow cellularity. Fatty tissue predominated, with scattered strands and small collections of nucleated elements. The

H. B., and L. W.) were in cases of relatively rich marrow cellularity as seen in the sections. The total nucleated cell counts, while tending to be slightly higher than in the preceding group, did not attain levels that the marrow cellularity would seem to justify. This lack of correlation between the cellularity of aspirated samples and of tissue sections would seem at first glance to nullify the importance of studies of the former, and to support the contention of those (Scott⁶) who claim that counts of total nucleated cells are unreliable. However, somewhat similar results have been obtained in most cases of neutropenia, in occasional cases of leukemia, and in other types of anemia where despite rich marrow cellularity a degree of so-called maturation arrest occurs. It seems possible that the number of cells aspirated may be related to the amount of maturation.

General Findings at Necropsy

Postmortem examinations were made in 14 cases (see Table 5). Bone marrow findings have been described previously. The findings in other organs related to the hemopoietic system varied greatly. The liver was found enlarged in 4 cases. In each case this organ was pale and showed fatty changes. In several instances there was hemosiderosis, and in some a certain amount of focal necrosis.

The spleen was enlarged in 5 cases, although this feature was outstanding in but two. In 6 cases the spleen was smaller than normal. Recent infarction was found twice, hemosiderosis several times, and intrasplenic venous thrombosis once. Reticulum changes of varying degree were present in most of the cases. Lymph nodes were noticeably enlarged in one or more regions of the body in 5 cases. Deep-red, so-called hemolymph, nodes were conspicuous in several. Lymph node markings were normal in all cases.

Findings in other organs were extremely variable. Bronchopneumonia was present in

7 cases, and pleuritis in 2 others. In 10 cases diffuse hemorrhagic phenomena were present, and in 3 these seemed to be the most pronounced terminal features. In 3 cases ulcerative lesions, with or without sepsis, were present. However, in but 1 case was the ulcerative lesion the most conspicuous feature.

Treatment

The treatment employed in this series of cases varied greatly, and usually several measures were used at the same time in such a way as to preclude scientific evaluation of results. Of some fourteen measures (blood transfusion, intramuscular blood, iron, liver products, vitamins, yellow bone marrow, pentose nucleotide, x-ray, ultraviolet light, splenectomy, endoglobin, uterine curettage, sulfonamide drugs, and bone marrow transfusion), only blood transfusion was used throughout the series.

Despite the difficulty in evaluating results, observations of individual cases have led to the feeling that transfusion has occasionally been instrumental in prolonging life until a remission occurs. An attempt was made to learn the value of transfusion. Fourteen cases treated previous to January 1, 1938, received relatively infrequent transfusions (average of 1 transfusion in 7.8 weeks) while 20 cases treated after that date received an average of 1 transfusion in 4.9 weeks. The average survival periods for the two groups were 34.3 and 40.9 weeks, respectively, an increase of some six weeks. However, other methods of comparison lead to a certain amount of doubt as to whether this widely accepted therapeutic measure actually does prolong life noticeably.

Bone marrow transfusion as suggested by Morrison and Samwick⁷ was done in 4 cases. There was no evidence of beneficial results in any of them.

Clinical Course and Prognosis

The clinical course has been extremely variable. Five cases ran acute courses of from

dominance of cells resembling monocytes could not be corroborated at necropsy.

These findings in sectioned marrow tissue may be summarized as follows. The majority of cases have shown marked reduction in cellularity throughout. The remainder have shown degrees of cellularity varying from definite hypoplasia to hyperplasia. In the relatively hyperplastic marrow a marked irregularity has usually been noted, with areas of hypoplastic and hyperplastic tissue alternating. The constant finding in all cases has been the almost complete absence of mature myeloid and normoblastic elements.

Aspirated sternal marrow was examined in 15 cases, in 13 of which a uniform technic was employed. Exactly 3 cc. were withdrawn from the body of the sternum and placed in a bottle containing an oxalate mixture in a dry state.⁵ After thorough mixing, films were prepared and enumeration of total nucleated cells made. The films were stained with Wright's stain and differential counts were made. The results are shown in Table 3, and results of control studies on normal subjects in Table 4.

It will be noted that the various types of cells are grouped under 5 headings: (1) immature myeloid cells, including those easily identified as myeloblasts, myelocytes, and juveniles; (2) mature myeloid cells including band (stab) and filament polynuclears; (3) lymphoid cells including all cells resembling

lymphocytes; (4) miscellaneous cells, including monocytes, plasma cells, reticulum cells, unidentified cells, disintegrated cells, etc.; (5) nucleated red cells. This grouping was adopted for the purpose of simplifying interpretation and of avoiding, as far as possible, confusion regarding controversial terminology and cell identification.

Comparisons of the average absolute counts in the two tables will show a pronounced deficit, not only in the total cellular content, but also in each of the cell groups. Practically all of the individual cases exhibited this deficit throughout the groups, although in varying degrees. In one case (L. M.) the numbers of miscellaneous and of nucleated red cells actually exceeded the average of those groups in normal subjects. This was a case of chronic anemia following exposure to benzol. In the same case the number of immature myeloid elements exceeded the lowest count found in normal subjects. In another case (A. D.) this was true for immature myeloid and nucleated red cells, and in still another (H. B.) it was true for nucleated red cells.

In 7 cases it was possible to compare the results of studies of aspirated marrow with those of tissue sections. Four of these (C. L., C. G., V. S., and B. R.) were in the group previously shown to have aplastic marrow. All of these showed total nucleated cell counts below 7,000, corresponding roughly to what might be expected. The other three (N. B.,

of distribution of all types of blood elements. It is probable that in some cases this failure of maturation may be the only abnormality, although varying degrees of actual tissue damage, at least in the bone marrow, may result also. Only on some such basis as this is it possible to explain the variable clinical picture, course, and prognosis, and the blood changes and tissue findings.

This view is supported by the observations that all variations can be found in cases due to definite hemopoietic poisons, such as arsenicals and benzol, and that such cases do not differ in any major respect, except possibly that of prognosis, from those cases in which the cause is undetermined.

The present study has shown that the disorder can occur at any age, in either sex, and in a variety of racial and vocational groups.

The clinical findings include symptoms and signs of anemia, hemorrhagic disease, and less commonly of ulcerative processes. In addition, febrile reactions and gastrointestinal disturbances are very common. Of unusual interest in this group was the comparatively frequent finding of lymph node, splenic, and hepatic enlargement.

With few exceptions the cases exhibited the classical triad of blood findings—severe anemia, leukopenia, and thrombocytopenia. The anemia was of the normocytic orthochromic type in only slightly more than half of the cases. Minimal signs of regenerative activity were found in the blood, and signs of excessive blood destruction were not observed. A leukopenia of less than 3,000 was found in 70 per cent of the cases. This leukopenia, in most cases, was the result of absolute deficit in all types of cells, and not simply a neutropenia. Immature cells in small numbers were encountered in a minority of the cases. Thrombocytopenia was almost, but not quite, a constant finding, and while the presence or absence of hemorrhagic symptoms usually seemed to depend upon whether the number of platelets was below or above the so-called "critical" level, this was not always true.

Bone marrow, as observed in sectioned tissue, varied from extreme hypoplasia to actual hyperplasia. A common finding was an irregular distribution of elements with islands of hyperplasia alternating with those of hypoplasia. The constant abnormality was the relative paucity of mature cells, interpreted as evidence of maturation arrest.

Aspirated marrow examined by a standard technic showed a remarkable deficit of nucleated cells, in which all of the main cell group-

ings took part. This lack of cellularity did not always correspond with the degree of cellularity observed in sections, and it is hypothesized that this is explained by the lack of more mature and easily dislodged elements. At any rate, it is believed that the findings in aspirated marrow are often of greater diagnostic value than those in tissue sections.

Postmortem findings in most of the cases were essentially those of profound anemia, hemorrhagic diathesis, and terminal infection. A few ulcerative and associated septic lesions were encountered.

There was no evidence that any type of treatment exerted a specific effect. Transfusion of blood was thought to be the most effective supportive measure, and there is reason to believe that frequent use of this measure may prolong life, and, in certain instances, actually preserve life until spontaneous recovery occurs. The use of bone marrow transfusion in a few cases did not seem to alter the course of the disease.

A few cases recovered entirely. In the great majority, death resulted in from a few weeks to about thirty-three months. There was no sharp dividing line to distinguish acute from chronic cases, except the duration of the disease.

Diagnosis has been found to be difficult, since some cases have failed to exhibit characteristic findings during life, and other conditions have been found to masquerade as aplastic anemia. A few instances where leukemic changes have appeared as terminal events in otherwise classical aplastic anemia raise the question of whether such changes may not be the result of some compensatory mechanism.

Conclusion

Aplastic anemia may be regarded at the present time as a disorder of varied manifestations, in which the fundamental defect is one of general hemopoietic insufficiency, varying from inhibition of normal cell maturation and distribution to actual hypoplastic changes.

two to four weeks, after which improvement began and was followed by complete recovery. These patients have been observed for periods of from thirteen months to eight and a half years without evidence of recurrence being noted. In a small proportion of cases the disorder was rapidly progressive, with death occurring in from twenty days to a few weeks after the onset. In the majority, the disorder was gradually progressive with partial remissions after one or several transfusions. In these cases the duration of the illness varied from three to thirty-three months before death resulted.

The results as of April 30, 1941, were as follows: complete recovery, 15 per cent; death, 73 per cent; pending, 12 per cent. There is fair reason to expect that in this group of patients the final mortality rate will be 85 per cent.

In order to study the prognosis from the standpoint of causative agents, the cases in which the final outcome was known were classified tentatively in four groups, namely: cryptogenic, in which no possible cause was found; arsphenamine; benzol; and miscellaneous, in which pregnancy toxemia and military tuberculosis were noted. The results are noted in Table 6.

TABLE 6.—PROGNOSIS AS RELATED TO CAUSATIVE FACTORS

	No. of Cases	Percentage Fatal	Percentage Recovered
Cryptogenic	18	89	11
Arsphenamine	6	67	33
Benzol	2	100	
Miscellaneous	4	50	50

Naturally one could hardly be permitted to draw far-reaching conclusions from the small number of cases represented, especially since the classification is subject to criticism as mentioned earlier. However, the results certainly indicate an extremely high mortality for the series as a whole, and, in line with the results of numerous other workers, a somewhat better prognosis in secondary cases than in strictly cryptogenic cases.

Diagnosis

Experiences of the writer have led him to agree with such writers as Dameshek,⁸ who say that the diagnosis of aplastic anemia is a difficult one. This is especially true if the period of observation of the case is relatively short. While the majority of the individual cases have fallen into a pattern of almost monotonous uniformity, as far as most of the criteria are concerned, there were several that

failed to conform to it. In addition, several cases have been encountered that showed the essential characteristics of this disorder, only to have the diagnosis disproved by subsequent events.

In the present study the cases tended to group themselves in three categories: (1) early findings suggested aplastic anemia, and subsequent events substantiated the diagnosis; (2) early findings suggested aplastic anemia, and subsequent events tended to disprove the diagnosis; (3) early findings did not suggest aplastic anemia, but subsequent events tended to make that diagnosis fairly definite.

The first category represents cases that were typical throughout and requires no further comment. Cases falling in the second category were of two types. The first consisted of cases later found definitely to have some other disease masked as aplastic anemia. The second consisted of cases more difficult to interpret. They are cases that ran prolonged courses in which all findings, including bone marrow abnormalities, were typical of aplastic anemia, and the terminal stage and necropsy findings were those of acute leukemia. While such cases, too, may be interpreted as leukopenic leukemia masked as aplastic anemia, it is possible that the leukemia developed as a sort of compensatory reaction to long continued bone marrow insufficiency. Such cases have been described and are summarized by Hunter.³ The present author, together with Terplan and Sanes, has reported one case in this category.⁴ The cases of the third category showed characteristics that tended to confuse the diagnosis. In some the clinical, blood, or bone marrow findings were not typical of aplastic anemia, i.e., leukopenia or thrombocytopenia might be absent, or the character of circulating and bone marrow cells suggested leukemia. In one case the findings were strikingly similar to those in pernicious anemia. In all of these cases terminal events and necropsy findings revealed evidence of aplastic anemia.

Summary and Comment

The results of this study lead the author to incline toward the view that the disorder spoken of as aplastic anemia should not be too strictly defined as characterized by any set of clinical or pathological criteria. It seems more likely that it should be regarded somewhat broadly as a defect of the entire hemopoietic apparatus, in which the principal abnormality is inhibition of maturation, and consequently

FIG. 1. Basal cell epithelioma of scalp with bone involvement, treated by two courses of x-rays of 165 kv. 4 ma. at 50 cm. distance, with 0.25 mm. copper and 1 mm. aluminum filter, 300 r daily for eight days—total, 4,800 r. Right hds temporarily sutured

cutaneous cancer, and most of these are needless. These cancers, theoretically at least, could have been prevented in every instance. Also, early diagnosis and proper treatment probably would have cured all of these cancers.

Hence the importance of prophylaxis, of early diagnosis, and of wider dissemination of knowledge on this subject.

Summary.—preventive treatment is based on an understanding of the pathogenesis of skin cancer. Preventive treatment consists of: (1) avoidance of habitual excessive exposure to sunlight, especially by persons who have fair skins; (2) maintenance of a healthy, youthful skin by adequate, nutritious diet and good general health; and (3) early and prophylactic removal of moles, warts, cysts, and other precancerous lesions.

Biopsy

In each instance in which skin cancer is suspected, a specimen of tissue should be removed for pathological examination. Biopsies can practically always be done without noticeable scarring, and it is now generally agreed by pathologists that such a procedure is safe.

The biopsy punch is an objectionable, outmoded instrument that conflicts with the tenets of good plastic surgery. For instance,

if one is to avoid noticeable scarring, an incision should be at least three times as long as it is wide, and the long axis of the incision should be in the direction of the lines of tension in the skin. Therefore, those who wish to do biopsies with a minimum of scarring should discard the biopsy punch if they have not already done so, and instead use a scalpel (Bard-Parker #15). Such incisions should be carefully closed with interrupted fine silk sutures which should be removed after four or five days.

For the treatment of unusually small lesions of a few millimeters' width, "biopsy excision" is good practice. This means excision for pathologic examination of the whole lesion, and a margin around it ample enough to include any outlying parts of the growth.

Whether it is safe to do biopsies on melanoma, or on lesions suspected of being melanoma, is a question upon which there is some disagreement. We personally believe that it is a safe and legitimate procedure. We have discussed this subject with several outstanding cancer pathologists and cancer surgeons. Their opinions were divided. About half were vehemently opposed to doing biopsies on melanoma, whereas the other half confidently approved them. None had ever seen any metastases that could be ascribed to doing such a biopsy, but the surgeons in particular

MODERN TREATMENT OF SKIN CANCER

GEORGE C. ANDREWS, M.D., and MAURICE C. BARNES, M.D., New York City

PRESENT-DAY preventive treatment of cancer of the skin has reached a high degree of efficacy. It is based upon information gleaned from clinical studies of the pathogenesis of skin cancer. A fact often not recognized is that such clinical studies have been, as a whole, more productive than laboratory research and have formed bases for most laboratory investigations of the causes of cancer.

The predisposition of certain types of skin to the development of cancer has been established by clinical observation. Likewise by clinical studies, the influence of heredity on skin cancer has been clearly demonstrated. That we as individuals tend to inherit the same kinds of skin our parents possessed, and that fair skins are more likely to develop cancer than brunette skins, are facts well known. Also, there is probably no fact regarding the cause of cancer better established beyond question or doubt than that habitual actinic exposure causes skin cancer in certain types of skin under certain conditions. Purely clinical observation has fully established this well-known and important fact, which has also been confirmed by many laboratory experiments on animals.

Exposure to sunlight seems to increase the maturity of all living things. For instance, a plant which is grown in a dark cellar will grow large but does not flower until it is placed in the sunshine. On the other hand, consider the early age at which children mature in the tropics. These examples may illustrate the effect of habitual actinic exposure upon the cells of fair, sensitive skins. The life cycles of such cells apparently are speeded up and the exposed skin ages prematurely. Cancer is a disease of old age, but old age is a biologic—not a chronologic—fact, and all parts of the body do not age uniformly. Some relatively young people have old arteries, whereas others have prematurely old skins, and still other people have in their seventies skins which appear youthful.

In all normal people there exists a mechanism of protection against the injurious effects of excessive actinic exposure. This does not seem to be simply a matter of quantity of pigment. In addition to the quantity of pigment, there appear to us to be some further

protective forces, possibly of the nature of enzymes. Some children born of consanguineous marriages lack this protective mechanism. These unfortunate individuals develop senility of the skin during childhood (xeroderma pigmentosum), and usually die of skin cancer before reaching adult life.

One-third of all skin cancers occur on the nose, and this may be due at least in part to the large amount of sunlight the nose receives. Cancer of the lower lip can be traced in practically all instances to habitual exposure to sunlight, with resultant actinic cheilitis. Smoking plays a questionable role. The male-sex incidence of lip cancer, like the female-sex incidence of mammary cancer, is not as yet explained.

As Ewing has repeatedly pointed out, and as we believe largely from clinical observations, there probably is no single cause of cancer, and cancer is not as simple as a cause-effect reaction. Cancer is a process that arises under a certain group of favorable conditions. In the case of skin cancer, the chief conditions are maturity, fair skin, and habitual actinic exposure.

And the likelihood of cancer is augmented if in addition there are moles, warts, or other so-called precancerous lesions present, and by contact, occupationally or otherwise, with pitch, tar, paraffin, lubricating oils, or other hydrocarbons containing dibenzanthracene or similar carcinogenic substances. It is interesting that these have chemical formulas similar to those of the estrogenic hormones, which also are potent stimulants of cell growth. Rhoads³ and his coworkers have shown in animal experiments that nutritional deficiencies, particularly of vitamins, play some sort of etiologic role in some cancers. It appears that animals on adequate diets have the power to neutralize certain carcinogens, whereas those on deficient diets fail to neutralize such carcinogenic substances and so develop cancer.

It is truly stated that skin cancer is a preventable disease. General cognizance of the group of factors which favor the development of malignant growths of the skin will do much to decrease still further the number of deaths from these annually. The list of precancerous lesions is now common knowledge and we shall not reiterate. There are over three thousand deaths in the United States annually from

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

The size of the dose may be changed slightly for the individual case. As a rule young people require slightly smaller doses and very old people slightly larger doses than the standards which we have recommended. If preferred, the same doses may be given daily for eight days instead of semiweekly for four weeks. Also, a 3-mm. aluminum filter can be used at 135 kv., giving 600 r daily for eight days—a total of 4,800 r. Unfortunately the histologic structure of the particular squamous cell epithelioma does not assist much in making a determination of the size of the dose.

Squamous cell epitheliomas on other portions of the skin surface, including the cheeks, ears, and scalp, should be excised surgically. This is usually a simple operation which can be done in the office under local anesthesia. Squamous cell epithelioma on the hands should generally be excised, but there are exceptions. The warty, nonulcerated, small epitheliomas, sometimes called hornifying papillomas, that occur in senility on the dorsa of the hands, are not serious and are easily cured by x-ray treatment. A single dose of 1,600 to 2,000 r is usually sufficient. On the other hand, one may encounter advanced ulcerated epithelioma on the dorsal surface of the hand, or on a finger, that requires major surgical care and dissection of the axilla.

The electric cutting current has a special field of usefulness in the treatment of some epitheliomas that arise in chronic radiodermatitis, especially those located on the nose, chin, or anterior chest, where the skin is atrophic and hidebound. An electrode shaped like a hockey stick has been extremely useful to us in such cases, and the healing and cosmetic results have been splendid. Electrosurgery often makes it unnecessary in such instances for the patient to undergo tedious and expensive surgical care.

In New York City the treatment of carcinoma of the lips, penis, vulva, and of other mucocutaneous junctions is not generally undertaken by dermatologists. We realize that in some parts of the country other practices prevail and that the dermatologist may obtain splendid results by x-ray and radium therapy in these cancers. However, in the enormous medical centers in New York the practice of physicians is highly specialized, and cancers of these parts of the body are treated largely by the surgical staffs, with occasional recourse to the radiotherapy department.

We should like to mention, furthermore, the value of liver extract injections and of

nicotinic acid therapy as supplementary measures in the treatment of oral precancerous conditions.

Basal Cell Epithelioma.—Basal cell epithelioma is chiefly treated by the use of x-rays, although when the lesions are small and in favorable locations, excision is preferred. The x-ray treatment which was recommended for squamous cell growths on the nose is applied to basal cell epitheliomas and mixed cell epitheliomas not only on the nose but in practically all other areas. Total doses of 6,000 r, to 8,000 r, as previously described, divided into two treatments a week for three or four weeks, usually the latter, are recommended, and even higher amounts can under certain conditions be safely and effectively given. We also use with success the divided high voltage technic, along the lines recommended by the Martins,¹ and we favor this method where the infiltration is deep. With this technic at 165 kv. 4 ma. at 50 cm. distance and a filtration of 0.25 mm. copper and 1 mm. aluminum, the erythema dose is a little under 600 r. We give 300 r daily for eight days, exclusive of Sunday, and two weeks after this first course of 2,400 r we give a similar second course. This makes the total dose 4,800 r, which is theoretically a little low but has been adequate in most of the cases we have thus far treated. A third course can be given without entailing hazard if it is necessary. The skin reaction to this high-voltage divided-dose method is inconspicuous, and has consisted simply of a vivid erythema that appears about a week after the first course and persists with minor variations until three or four weeks after the second course.

X-ray Technic

In 1936 Braestrup and one of the present writers (Andrews)² reported studies of depth-dosage measurements in the skin at distances of millimeters beneath the surface. At that time we pointed out that the ideal radiation for treatment of skin lesions was theoretically a homogeneous beam of about 0.9 angstrom, of which about 87 per cent would be absorbed in the first centimeter of tissue. We recommended at that time a change from the then standard technic of 90 to 100 kv. to lower voltages such as 50 to 60 kv., and the use of a filter of 2 mm. aluminum, so as to obtain a fairly uniform beam of about 0.9 angstrom. We are gratified that recent tendencies have been along the lines suggested, and are still convinced that our recommendations were sound. Keeping in mind that even skin

FIG. 2. Basal cell epithelioma of nose before and after treatment with divided-dose x-ray as described in legend under Fig. 1.

seemed to fear dire results, which opinion was not generally shared by the pathologists.

Treatment

Having fully established the character of the growth by clinical diagnosis confirmed by pathologic examination, we are prepared to plan the treatment. In general, this is surgical excision for squamous cell carcinomas, and x-ray treatment for basal cell carcinomas. For melanomas, radical surgical removal is the only treatment. Radium treatment of skin cancer has been largely discarded in our clinic. The use of the so-called electric cutting current for the removal of skin cancer by electro-surgery has value in selected cases.

Squamous Cell Epithelioma.—Treatment of squamous cell epithelioma is particularly influenced by the location of the lesion. Those which arise upon the nose or midportions of the face, although numerically common, are not likely to metastasize and, although they have great tendency to recur locally, are relatively less malignant than those which arise on other parts of the integument. The nose is a difficult place for plastic surgery, and excision of epithelioma from the nose is generally a difficult job that may involve months of disfigurement and disability for the patient. For these reasons, and because x-ray treatment effectively cures such cancers, it is the preferred method.

The x-ray dosage is influenced somewhat by

the size of the lesion and the age of the patient but in general is 1,000 r twice a week for four weeks, making a total of 8,000 r, using 65 kv. 20 ma. at 14 cm. distance with 1 mm. of aluminum filter in a modern shockproof machine, with oil-immersed Machlett tube. An ample ring of tissue is exposed beyond the visible margin of the tumor, generally as wide as the diameter of the lesion itself. If this low voltage technic is not feasible because your x-ray apparatus is not adapted to it, nearly as good results can be obtained by using 100 kv. 3 ma at 20 cm. (8 in.) distance with a broad-focus Coolidge tube unfiltered, which was the standard setup before the shockproof equipment was developed. With this old Coolidge tube unfiltered technic at 100 kv., one should give 750 r twice a week for four weeks, making a total of 6,000 r.

The reaction in and about the epithelioma from this intensive treatment is surprisingly small and consists for the most part of a dull erythema and a drying up of the lesion that becomes noticeable after the third treatment. The reaction gradually becomes more vivid, and during the fourth week of treatment, and the week following, there is a superficial ulceration which requires a dressing. This ulceration rapidly heals and the reaction promptly disappears, concomitantly with the involution and disappearance of the tumor, so that the whole process is finished within three weeks after the last treatment.

CONTACT DERMATOSES

IRVING SWARTZ, M.D., Syracuse, New York

CONTACT dermatitis is another of the many skin conditions rescued from the grab bag of the all-inclusive term eczema. At present it appears to be among the most interesting to the physician, because it stimulates his curiosity as a detective, and because of the satisfaction that the solution of the problem gives to the patient and himself.

Contact dermatitis is an inflammation of the skin brought about by the action of animal, vegetable, or mineral substances on the skin surface. The irritants may be primary irritants that produce inflammation on any skin. Or they may be substances that are usually nonirritating to normal skins but produce dermatitis in sensitized skins. We are concerned here with the dermatoses that develop from this secondary group. The offending agents are innumerable and an excellent list appears in Weber's article.¹ The dermatitis can occur on any part of the body, from the scalp—as with injury from a hair lotion—to the feet, as with injury from the dye or leather in shoes.

The greater number of cases occur on the exposed areas of the body, as the head, neck, arms, and legs; and these are easier to diagnose. The unexposed areas may also be involved, and these cases may be a bit more puzzling until the solution strikes one. The problem of solution puzzled one physician consulted about a concentric dermatitis on the buttocks of a child. The usual therapy did not have much effect. Observing the child's buttocks from a distance one day, he asked the mother whether there was a new toilet seat in the home. Yes, there was a recently painted toilet seat—and so another mystery was solved.

Among the commoner substances which may produce a contact dermatitis or dermatitis venenata are: poison ivy, oak, and sumac; the geranium, the primrose, the ragweeds, resorcin, quinine, mercury, novocain, butyn, orris root, and that very common dye, paraphenyldiamine. Any tree, weed, or plant may be incriminated. Sulfur, Whitfield's ointment, and adhesive tape are frequently at fault. Schwartz and Tulipan² state that the majority of occupational contact dermatoses reported in the United States are caused by

alkalies, oils, solvents, dyes, poisonous plants, and acids.

In going over my own records, I found the following substances, in the order of frequency here shown, to be the causative factors in cases of contact dermatitis or dermatitis venenata: poison ivy and related plants, alkali soaps, orris root face powders, mercury, sulfur, paraphenyldiamine (in furs, dresses, and hair dyes), Whitfield's ointment, adhesive plaster, cements, nickel, novocain, mercury and iodine forming mercuric iodide. Substances infrequently producing dermatoses were: resinol salve, D.D.D. liquid, lysol, noxema, phosphorus, pyrethrum, gas cleaning fluid, carbon typewriter paper, Japanese lily, mango plant, Oakite liquid cleanser, rubber, wool, paint.

Diagnosis

The diagnosis of contact dermatitis is made from the very sudden onset of a severe itching or burning dermatitis, varying from a simple erythema to papule, vesicle, pustule, and gangrene formation. The exposed parts of the body are affected more commonly. A careful history of contacts is very important and that alone may be sufficient at times for making the diagnosis. The history must include the time of onset, whether at work or at home or following a vacation, and information as to use of new cosmetics, plants in the home, animal pets, use of insecticides, hobbies. Repeated talks may be necessary. The patient may mull over in his mind what things have been disturbing him with itching, for example, and suddenly strike on the right substance as the irritant contact. An important aid in confirming the diagnosis is the epidermal patch test.

In the differential diagnosis an exudative neurodermatitis must be excluded. This condition does not show vesicles and is more inclined to be patchy. The intense edema of the eyelids and genitalia seen in a contact dermatitis is not seen in neurodermatitis. The eyelids are not involved as a rule in neurodermatitis or atopic dermatitis.

Patch Test

The patch test is an epidermal sensitivity test. The test is an attempt to reproduce on

¹Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

tumors do not usually extend more than 2 cm. in depth and that most dermatoses do not go deeper than 1 cm., it is obviously desirable for dermatologists to use a quality of radiation which produces absorption relatively less in the depths, and more in the lesion itself. It is generally agreed that the biological effects of x-rays on a tumor are due solely to the quantity of energy absorbed in the area of the tumor. This principle must be the basis for x-ray therapy if we are to obtain the maximum benefits from its use.

It is desirable that the absorption of the radiation be evenly distributed throughout the tumor area. According to our studies, the quality of radiation produced by 50 to 60 kv. and a filter of about 1.5 mm. aluminum is much more homogeneously absorbed throughout the first 2 cm. of tissue than the radiation produced by 100 kv. unfiltered.

The divided-dose technic aims to maintain a saturation dosage over a period of several weeks, and thereby to irradiate abnormal radiosensitive cells with a heavy lethal dose during their mitotic periods, in which they are particularly susceptible. This sound plan of dosage, combined with the use of a quality of radiation which is absorbed almost wholly within and relatively evenly throughout the area of the tumor, forms the modern x-ray treatment of cutaneous cancer.

Discussion

Dr. Paul E. Bechet, *New York City*—Dr. Andrews has presented an excellent paper, and the results of treatment in severe and extensive epitheliomata as shown on the screen are very satisfactory, but it would seem to me that as regards smaller lesions, particularly of the infiltrated type, with raised and almost sclerosed borders, it would be better to destroy them first with electrocoagulation, followed by thorough curettage of the whole softened mass, then desiccation of the surface, and the administration of a single dose of unfiltered x-ray, using the broad-focus Coolidge tube at 100 kv., giving 900 to a top of 1,200 r. I have used this method for some seventeen years with extremely satisfactory results, both from a cosmetic point of view and permanence of cure.

About twelve years ago I treated a patient who had a large basal-prickle cell epithelioma on the forehead, about 6 cu. mm. in diameter. The mixture of two types was proved histologically. Under local anesthesia the lesion was electrocoagulated, then thoroughly curetted, the surface desiccated with a strong spark, and 1,200 r of unfiltered x-rays given, all at the same time. I saw this patient a few months ago and she was still well after twelve years. The scar was smooth, soft, and pliable.

AMERICAN DIABETES ASSOCIATION TO MEET

The second annual meeting of the American Diabetes Association will take place on Sunday, June 7, at Haddon Hall in Atlantic City.

The morning session will begin at 9 o'clock and will include a business meeting, a presidential address, and a round-table discussion. The chairman of the discussion committee is Herman O. Mosenthal, M.D., and the members are Charles H. Best, M.D.; Joseph H. Barack, M.D.; Edward S. Dillon, M.D.; and Elliott P. Joslin, M.D. There will also be an educational film on diabetes, from the Medical Society of the State of Pennsylvania.

The afternoon scientific session will begin at 2:00 P.M. and is as follows: "Action of Insulin" by Franklin B. Peck, M.D.; "The Diabetic in the Defense Program," by Joseph T. Beard-

wood, Jr., M.D.; "Endocrine Control of Carbohydrate Metabolism in Relation to Human Diabetes," by C. N. H. Long, M.D.; "The Storage and Significance of Tissue Glycogen in Health and Disease," by Samuel Soskin, M.D.; "Acidosis," by Eaton M. MacKay, M.D.; "Hypoglycemic Reactions," by Harold E. Himwich, M.D.

If time permits, the following papers will also be read: "Insulin Atrophies," by Alexander Marble, M.D.; "Vitamins and Diabetes," by Julian M. Freston, M.D., and Winifred C. Loughlin, M.D.

The evening session, at 7:00 P.M., will begin with dinner, followed by the Banting Memorial Lecture, "An Analysis of Statistics Bearing on Diabetes Mellitus," by William Muhlberg, M.D.

AMERICAN HEART ASSOCIATION TO MEET

The eighteenth scientific meeting of the American Heart Association will be held June

5 and 6, 1942, at Chalfonte-Haddon Hall, Atlantic City, New Jersey.

acid. Tense vesicles are opened to relieve the discomfort and pain. Later, when the eruption is subacute, drier, and more scaly, a calamine lotion with some olive oil is quite soothing. Soap and water must be omitted entirely.

Of course one must eliminate every suspected irritant until a positive diagnosis is made. If the patch tests are negative and one is still suspicious of a contact, the suspected substances may be brought in contact with the patient one at a time, at intervals of a few days. Specific therapy may be used, for example, with poison ivy. However, if a polyvalent sensitivity develops, specific therapy may not work, and nonspecific therapy, such as autohemotherapy or milk injections, may be attempted. Treatment and diagnosis at the earliest possible moment are important, to prevent a simple monovalent sensitivity from developing into a more resistant polyvalent sensitivity. In applying salves or lotions to an already sensitized skin, it is well first to patch-test the effect in each instance on a small area of normal skin. Baths containing oatmeal, baking soda, bran, starch, or boric acid are often of value.

Prognosis

On removal of the irritant the dermatitis will subside. Early removal prevents a polyvalent sensitivity in many cases. Even a monovalently sensitive skin is more susceptible to irritants after recovery.

Case Reports

Case 1. *Pyrethrum Dermatitis*.—A gunsmith, 55 years of age, who was seen at his home, adjacent to his place of business, which he conducted together with a taxidermist, presented an erythematous, diffuse, oozing vesicular eruption involving only his arms and legs, of seven weeks' duration. His face, neck, and torso were clean. He was so weak from loss of sleep and nutrition that he was now in bed.

He had had no previous skin complaints. This eruption apparently started after he had mopped a floor with a new soap. After the eruption started, various home remedies (noxema, bichloride of mercury, sulfur ointment, etc.) were applied, with aggravating effects. All patch tests were negative. The patient responded well to the usual soothing compresses, but suffered a relapse every week end.

In going over the history of possible contacts, mention was made of intense pruritus which might follow contact with the irritant. The patient kept wondering why he was worse during week ends, although so well during the week. Then he recalled that the taxidermist who conducted the shop with him worked only on week

FIG 2. Flexor aspect of forearms, showing positive patch test of adhesive below on left forearm. Other areas show negative patch tests, but positive areas where adhesive was applied. Coloring matter was added later for contrast in photographing.

ends. On Friday he was feeling fairly well, and wondered if his week end was going to be bad. The door connecting his home and shop was open. He heard the taxidermist using a spray on some animal skins. Some of the spray evidently floated into his room, and within a few moments an intense pruritus developed on his own skin. He immediately connected the spray with his dermatitis, and a severe positive patch test confirmed the diagnosis. Shur-Deth spray, containing pyrethrum, was the offending agent. As soon as this was stopped, the eruption cleared up.

Incidentally, this patient used to think that skin specialists were only for beautiful women, but has now changed his mind.

Case 2. *Adhesive Dermatitis* (Figs. 1 and 2).—A salesman, aged 35, was cut on the face by barbed wire. Five sutures were taken, then tincture of metaphen and a gauze dressing with adhesive tape were applied. A tetanus antitoxin injection was given. On removal of the dressing two days later, the laceration was apparently healing, but an erythematous vesicular eruption was noticed along the edge of the bandage, where the adhesive was in contact with the skin. This was diagnosed by the attending physician as impetigo contagiosa and a 5 per cent ammoniated mercury ointment was applied with another dressing and adhesive. The vesicular itchy eruption spread over the entire face and made no response to various remedies used.

When seen twelve days after the original injury, the entire face was swollen, erythematous, and moist. Patch tests with various remedies (5 per cent ammoniated mercury, bichloride of mercury, lotio alba, noxema, etc.) were negative. A patch test with adhesive was strongly positive. The eruption responded quickly to soothing topic remedies. There was no history of any previous sensitivity to adhesive.

Case 3. *Phosphorus Dermatitis*.—A manager of a brass foundry, aged 49, presented an itchy,

FIG. 1. Contact dermatitis from adhesive, involving entire face.

a normal area of the skin, usually the flexor aspect of the forearm or the back, the circumstances under which the patient's eruption developed. The substance applied must be not a primary skin irritant, that is, it must be one not irritating to the skins of all persons to whom it is applied. The test substance should preferably be in a moist condition. Water or perspiration may be used to moisten the substance. Perspiration may be obtained by placing the substance to be tested in the axilla for a few hours. However, artificial perspiration³ may be prepared and used. At times this is more useful than water, as it more closely simulates actual conditions.

A half-inch square of skin of the flexor aspect of the forearm is covered with the moistened material to be tested. This in turn is covered with a larger piece of gauze or muslin, and then with another covering of waxed or oiled silk, and finally with adhesive to hold the materials on the skin.

A far simpler method⁴ when testing cements, ointments, or volatile oils, is to cover the substance with scotch tape and rim with adhesive. This is easy to observe at short intervals of fifteen minutes while the patient waits. The test is inspected at twenty-four, forty-eight,

and seventy-two hours. If the patient complains of itching or burning at the test site, it may be necessary to remove the test in less than twenty-four hours. Some test material may be left on as long as a week.

A positive test will show a typical dermatitis picture, going through the stages of itching or burning, erythema, edema, and vesiculation. A papular or pustular reaction about the hair follicles or sebaceous orifices is not considered a positive test.

Patch testing, if done at the time of the eruption, may produce a severe reaction locally and aggravate the eruption present. The testing should not be done at the site of the eruption until the skin has been allowed to quiet down for a long time.

If possible, use for test the same material as the patient has used. Proprietary preparations may change from jar to jar. Sometimes a combination of materials used may produce a dermatitis, whereas the individual components are harmless.

Patch tests indicating an epidermal sensitivity may be positive in contact dermatoses, but usually are negative in atopic dermatoses. The fact that the tests are negative would tend to point toward atopic dermatitis. Patch tests positive in atopic dermatitis are usually papulopustular and discrete, as distinguished from a diffuse erythematous vesicular reaction in contact dermatitis.

Patch tests performed on skin adjacent to the eruption are more likely to give a positive reaction. Negative patch tests may be interpreted as follows:² (1) the material tested is not the one causing the dermatitis; (2) the area tested may not be as hypersensitive as the affected area; (3) if the test is done very late, the hypersensitiveness may have disappeared; (4) the test is not reproducing the same conditions of moisture, heat, maceration, friction, light, concentration, etc., as those in which the eruption occurred.

A delayed positive test may occur hours or days after the test is removed. If the test is positive after a long interval, seven days or so, it may indicate a sensitivity that has developed from the test material itself. Generalized dermatitis has been known to result because of a patch test done at the height of the eruption.

Treatment

In the very acute stage, soothing lotions and compresses are best, as Burow's solution, 1:8, potassium permanganate solution, 1:5,000 to 1:8,000, or saturated solution of boric

male worker in a cutlery factory, after a few months at the job of attaching steel knives to redwood handles, developed a vesicular itchy dermatitis on the hands, which gradually spread over his entire body. Patch tests with redwood were strongly positive. His job was changed and the eruption cleared up. Three years later, he was temporarily put on a job of stamping names on redwood handles, and a vesicular dermatitis again developed on his hands. His job has again been changed.

Summary and Conclusions

1. Diagnosis of contact dermatitis is dependent on a very careful history of contacts. The greater number of cases occur on the exposed surfaces. The patch test is confirmatory evidence and must be interpreted correctly.

2. The most common causes are poison ivy and related plants, alkali soaps, orris root face powders, mercury and iodine forming mercuric iodide, sulfur, the dye paraphenylenediamine (as present in furs, dresses, and hair dyes), adhesive plaster, Whitfield's ointment, cements, nickel, and novocain.

3. Diagnosis and treatment quite early are important to prevent possibility of a monovalent sensitivity becoming polyvalent.

Discussion

Dr. William F. Hoover, *Jamestown, New York*—Dr. Swartz has given us an excellent review of the contact dermatoses and of his experience with them. In dermatology, the more cases we see and study, the more proficient we become. Thus, it seems to me, as we see, read, and hear about more cases of contact dermatitis, we raise our suspicion index to an ever growing list of substances.

I agree with Dr. Swartz that when patch tests have failed, very practical help may often be had by exposing the patient to one or two substances at a time—e.g., clothing. In this way the actual method of exposure is approximated. The effect on the skin is, of course, carefully observed during this time. The use of artificial perspiration in patch tests was mentioned. I use it routinely and it has seemed to enhance the value of these tests.

FIG 5. Positive patch test with amido-azotoluene

In general, patch tests are valuable but imperfect aids. As time goes on, we shall probably depend more upon careful stimulation of the detective instincts of the patient and his family. We all see cases of dermatitis on skin areas under the trousers or shirt pockets, produced by articles habitually carried in them. "Kitchen" matches or matchboxes are often the culprits. Recently I saw a bus driver with a dermatitis venenata on the right anterior thigh. He always carried his change in the right trousers pocket. A patch test with an Indian nickel was positive. He now wears a change belt. To date he has had no trouble with his hands.

I should like to mention one series of cases recently seen. Possibly a more detailed report will be made later. In a mail-order house in a neighboring city, selling clothing, any article selected for sale is handled in very large quantities. About eighty women are employed in the office. Frequently each one is given a sample of an article to wear before it is put on sale. In this case a large lot of hard-twist, good-quality beige silk stockings was ordered from one of the big manufacturers. A pair was given to each of the eighty girls.

Ten of the girls developed dermatoses. The eruption was at first distinctly confined to the areas covered by the stockings, but in several patients, in from one to two weeks, it spread and became generalized. The arms, face, and eyelids were then particularly involved. The original dermatitis had an urticarial appearance with perifollicular grouping. This suggested absorption, in perspiration, of dye or finishing material, as mentioned by S. J. Fanberg in the *J.A.M.A.*, August 3, 1940. At this time Fanberg called attention to the slow healing in his cases, which were of dermatitis due to wearing nylon hose. In my cases, pruritus was marked and healing slow.

No data as to material, dyes, or finishing products were obtained. The employers were very

FIG. 4.

FIG. 4. Same dye transferred to face, with vesicular dermatitis resulting.

erythematous, moist, scaly, diffuse plaque, about 4 inches in diameter, on the anterior upper third of the thigh and the same picture on the extensor aspect of the right third, fourth, and fifth fingers, of six weeks' duration. The eruption consisted of small vesicles at first, but was now in a sub-acute stage.

There was no previous history of skin complaint and no evidence of any fungus infection. All of the usual patch tests were negative. The eruption did not respond to topic remedies. Fractional doses of x-ray would involute the eruption for a short time and then a relapse would occur. The patient was becoming discouraged.

While talking with his physician one day, he pulled a wooden match out of his right pants pocket to light a cigarette. He stated that for years he had carried wooden matches in his right pants pockets. The solution was now apparent. Patch tests with phosphorus and also with the cloth of the right pants pocket were positive. The eruption cleared up as soon as he stopped carrying uncovered matches in his pants pocket. The right pants pockets in all of his suits had to be changed.

Case 4. Dye Dermatitis (paraphenyldiamine).—A hairdresser, blonde, thirty-eight years old, presented a diffuse vesicular dermatitis of the extensor and flexor aspects of the hands and forearms, of six weeks' duration. Her hands be-

gan to itch, burn, and swell soon after dyeing the hair of a customer with No-Tox (a hair dye containing paraphenyldiamine). Although she wore rubber gloves while applying the dye, she finger-waved the hair with her bare hands when the dye was dry. Patch tests with No-Tox and with paraphenyldiamine were strongly positive.

Cases 5 and 6 (Figs. 3, 4, and 5). Dye Dermatitis: amido-azotoluene (Oil Yellow T).—Two boys, both thirteen years of age, were presented at their confirmation with new wrist watches with black straps. Within three days, both developed severe vesicular eruptions on the wrists outlining the areas of contact with the black wrist straps. One boy also showed some vesicles on the face. Patch tests with the wrist straps were strongly positive. At about this time, Dr. Louis Schwartz published an article⁵ on dermatitis from wrist watch straps, in which he found the particular dye at fault to be amido-azotoluene, and this proved to be so in these two cases.

Case 7. Dye Dermatitis: Aniline Black.—A 26-year-old man developed a severe vesicular dermatitis on the feet and ankles within a few hours after wearing a new pair of cheap black socks on a hot day, when he perspired very much. Patch tests with the material were positive and aniline black was the dye that was found to be the causative agent.

Case 8. Redwood Dermatitis.⁶—A 23-year-old

SOME END RESULTS OF INTERNAL FIXATION OF THE HIP

WILLIAM WARD PLUMMER, M.D., and FRANK N. POTTS, M.D., Buffalo, New York

WITHIN the past ten years, more has been done to solve the problem of the fractured hip than had been accomplished in all of the preceding time. Whatever form of fixation was chosen, whatever method of application was preferred, it was designed first to reduce the fracture and second to hold the fractured surfaces together. Many of the accepted reasons for failure of union have been dispelled because these two fundamental principles of fracture treatment have been made applicable to the fractured hip.

Surgeons dealing with fractures, and certainly patients sustaining fractures of the hips, are indebted to the pioneers in this work. We have obtained a much higher percentage of united hips with excellent functional result, undoubtedly the patients have been much more comfortable, and, in all probability, the lives of many have been saved.

Internal fixation is an accepted procedure in practically all cases where it is applicable. As we have increased our familiarity with the procedure, it has become greatly simplified. However, it is still a procedure that necessitates meticulous care in its application.

It has been the writers' experience to participate in the treatment of approximately 125 cases of fractured hip with internal fixation. The work was started with Kirschner wires, which were found to be unsatisfactory. The Moore pins were used with satisfaction, but in the last few years we have confined our measures to the use of the Smith-Petersen nail. This is purely a matter of our personal choice, based upon limited experience with other methods, but a fairly extensive experience with the nail. We are satisfied with our method of reduction and of introduction of the nail. We are satisfied that the postoperative care of the patients has been minimized and simplified. We believe that the procedure is without doubt one of the great contributions to bone surgery. However, we find that there are certain patients with whom we have not obtained the desired results. Willing to accept good results, we must attempt to analyze the causes of the failures we have experienced.

We have made no attempt to choose a type

of patient or the type of fracture, as long as it was a fracture of the neck of the femur. We have taken these patients at all ages, the oldest being 93, and have not made the presence of a complicating lesion a reason for not operating. We have felt that these people were all living at their normal until the incident of the fractured hip, and that our responsibility was to restore them to that normal. We have had no reasons to regret this course. In none of the cases has the operative procedure produced any unusually worrisome postoperative shock; on the contrary, the patients have been made more comfortable and have been able to sit up in bed, and we are certain that we have avoided many complications that used to occur. We feel that the more simple, impacted transcervical fracture is just as much entitled to this form of treatment as the fractured neck with marked separation of the fragments.

We have not had the experience of handling any recognized pathologic fractures. We have had some difficulty on occasion in obtaining a perfect reduction, but, with the exception of one or two instances, we have felt that we obtained a satisfactory reduction. The failures we have had cannot be attributed to imperfect reductions. It has been observed that some of the difficulties in reduction were due to obliquities in the fracture line, in which we had extreme difficulty in maintaining the reduction. However, we were in all cases able to satisfy ourselves, at the time of operation, that we were maintaining a good position of the fragments and nailing them. In all probability, the obliquity of the fracture line and the placing of the nail may be very deceiving, and what appears at the time of operation to be a good positioning of the nail may not actually be so. Because of the obliquity of the fracture line, the nail does not get as firm a grip in the proximal portion of the neck and head as it would seem in the radiographs to have. We have reason to believe that this constitutes one cause of some of our failures.

We have felt that the valgus position was a good one, and that, if once obtained, no attempt should be made to change it. We have not always been able to obtain the most satisfactory position as far as rotation of the

helpful and I was enabled to see all of the 10 cases at least twice. A few other women in the group reported some pruritus. This may have been induced by suggestion.

Five of the girls washed the hose before they wore them. Patch tests with washed and unwashed stockings from this lot were done on all cases. A control of white silk material was used in each case. The controls were all negative. The washed material was moderately positive in only one case. The unwashed material was positive in 3 cases. Personal allergy histories were obtained for three of the girls (infantile eczema, 1; infantile eczema, and hay fever, 1;

urticaria, 1). Two other women gave definite family histories of allergy.

The time from exposure to the appearance of the eruption was two to fifteen days. The proportion of those among the group exposed who had trouble (12 per cent) is interesting.

In closing, a much larger series of cases, presenting heavy edema of the genitals followed by severe vesicular dermatitis after wearing new cheap cotton shorts, could be mentioned. This would take too long to discuss at this time. Most of you, I am sure, have had similar cases in the past few years.

Many thanks to Dr. Swartz for the presentation of his very good paper.

AUDIENCE RESPONSE TO "DOCTORS AT WORK" PROGRAM

Radio-program audiences may be checked in several ways. Audience mail response is one of the quickest and easiest, and, if interpreted conservatively, most satisfactory. Few programs receive audience mail in appreciable amount unless some effort is made to cause listeners to write. "Doctors at Work," the radio program of the American Medical Association and the National Broadcasting Company, now in its second season, has no product to offer for sale. To ascertain how many listeners would respond to an offer to send them printed material in the field of health education, in January, 1941, "Doctors at Work" offered a list of first-aid supplies and how to use them, suitable for pasting inside a medicine-cabinet door. This was announced on two successive programs, only one short reference being made at the end of each broadcast. The offer brought 8,200 letters and cards requesting the list. In April, just as the tourist season opened, another test was made. This time listeners were offered a chart and a table of highway health-and-accident safeguards. This offer, made in the same way as that in January, brought only 2,800 replies. In 1940-1941, "Doctors at Work" enjoyed the advantage of a favorable

evening hour, 10:30 P.M., EST, Wednesdays. In the 1941-1942 season a suitable evening hour was not available, and the series was opened on December 1 at 5:30 P.M., EST, Saturdays.

In a few weeks this time was switched to 5 P.M., EST, where it has since remained. In March, 1942, an offer was made to listeners to send them a check list of fifty factors which contribute to the health of home and family, an instrument by which their own health practices could be evaluated. The offer was made in the usual fashion—one short reference on two successive broadcasts. The number of replies exceeded 8,500 (8,500, March 24). It is impossible, of course, to estimate accurately the actual number of listeners from such responses. However, only small percentages of listeners respond even to an offer of more or less tangible objects, such as usable samples. In radio circles, the responses to audience mail tests here reported are considered highly satisfactory for a noncommercial program. "Doctors at Work" has a large following of faithful listeners. This following is nationwide; every state is represented in this response, as is Canada.

—J.A.M.A.

DIET OF AMERICANS IN GERMAN CAMPS

First accurate account of what American prisoners are fed in a German prison camp was made public by the American Red Cross, which described the diet as "slightly insufficient."

The American internees, about 300, are at "Lag VII," a prison camp at Laufen, near Salsburg, Germany, and are reported badly in need of cloaks, clothing, underclothing, and shoes by an International Red Cross Committee delegate who visited them. Headquarters here cabled \$5,000 to Geneva, Switzerland, for purchase of needed clothes.

The diet, which includes an unknown "food paste," is the same as that in other prison camps and consists of (per month): meat, 1,325 grams; fish, 248; margarine, 720; cooking fat, 320; food pastes, 500; marmalade, 770; potatoes, 4 kilograms; cabbage, carrots, 6 kilograms;

sauerkraut, 1,080 grams. In addition, there is a ration of 330 grams of bread per day. Usual menus: morning, tea substitute; noon, soup containing 40 grams meat, 25 grams beans, 10 of fat, a few potatoes; evening, same, sometimes kraut. Hygiene and disinfection were described as good. Internees are allowed one hot shower a week.

Red Cross nutritionists here immediately set about calculating the value of this diet in terms of calories and plan to send food packages to the American internees to supplement their diet.

Neither Red Cross nor government nutritionists here were able to say what the food pastes are. A guess was offered that they might be some kind of macaroni or other flour-and-water paste. The tea substitute also is unknown here.

—Science News Letter

trabeculation across the fracture line. We have had two cases in which there was intrusion of the nail, one of which produced symptoms while the other did not. When we have removed nails it has been because of the discomfort of extrusion or because there was an obvious nonunion and we were losing the position of the head.

It would seem from this review of unfavorable conditions arising after nailing of the hip that we still have some progress to make. We

are inclined to believe that the failures are in part due to the operators and in part to circulatory changes occurring at the time of injury. With proper reduction and adequate fixation, we have minimized further damage to the circulation, and in all probability this accounts for the very high percentage of good bony unions and satisfactory results. We are not yet able to detect the case that apparently has had too great damage done to the circulation.

"I AM AN AMERICAN DAY"

... will be celebrated in Central Park in New York City on Sunday, May 17, and "New York City at War" will be dramatized in a parade on Saturday, June 13. These joint festivals have

been planned to give every New Yorker an opportunity to participate in inspiring patriotic rallies. Mayor La Guardia has appointed Mr. Grover A. Whalen as chairman of both events.

head on the neck is concerned. We have had no reason, however, in the few instances in which that has occurred, to believe that it was a factor in the unfavorable result.

There have been no cases in our series in which we thought it necessary to open and reduce the fractured elements before nailing. We would qualify that statement to apply to fresh fractures.

It has been our feeling that, even though a perfect reduction was not obtained, if we had 75 per cent approximation of the neck to the head, which would allow for adequate placing of the nail, this would give us a satisfactory result. We have never felt that impaction of a fracture was a logical or practical procedure. Internal rotation produces sufficient impaction without any possibility of further damage to the precarious blood supply.

One of the difficulties we have experienced in a satisfactorily reduced fractured hip has been a protrusion of the nail through the upper part of the head. This has occurred in those cases in which the position of the nail in the head was high. We feel that the best position for the nail is in the center of the head, but that the position below the center is acceptable and preferable to the high position.

In all likelihood some of our failures have been the result of the nail being too high and too close to the cortex. We attempt in nailing to have the arms of the Y toward the upper portion of the head. This may be theoretical reasoning, but it would seem that there would be less chance of going through the bone with the nail in this position than there would be with the leg of the Y up.

Our postoperative fixation has been with a metal boot, with a transverse bar to prevent rotation. This is left on for a period of ten days or two weeks. We sometimes sling the leg from a Balkan frame, sometimes raise it upon pillows; either procedure adds to the comfort of the patient. The postoperative boot is applied more for comfort than in an attempt to stabilize, as we feel that the properly inserted nail is producing the desired fixation.

We allow these patients to sit up in bed any time after the operation that they so desire. This adds to their comfort and lessens the possibility of postoperative lung complications, and in a properly nailed hip should in no way put stress on the fixed fragments. We do not encourage them in lying on the side of the operation, but after the wound has healed, if they wish to assume that position, there is no objection to it.

Our first indications of trouble have appeared at varying lengths of time following operation. We have had patients perfectly comfortable for ten days or two weeks, then suddenly having a sharp pain in the hip, difficulty on motion, with x-rays showing that the end of the nail was not in the head, that it had either backed out or that in some way the head had become disengaged from the nail. In all probability this has occurred in the oblique fracture line or in the comminuted fractured area. Oblique fractures in the neck of the femur are more frequently seen than would be suspected.

We have had the nail slip back and in that way lose its hold on the head. By far the majority of the heads have been dense and hard, and it was easy to determine when the nail was entering the head; even in instances of that degree of density of the hip, we have had the nail slip back. We have had the nail slip back when the cortex through which it was introduced has been unusually soft. In some instances where the cortex was hard, and it was necessary to make numerous drill holes or chisel cuts to introduce the nail, the nail has slipped out. There is probably very little gripping of the head of the nail by the cortex, but that little is of considerable worth. We have, on occasion, reoperated these cases, driving the nail through its original tract and applying an internal fixation agent, such as a screw, and have then had the nail stay in place and the case go on to a very satisfactory result.

We have had an aseptic necrosis occur in a well-reduced and easily maintained fracture. In this case the fracture has repaired and the necrotic head has eventually undergone restoration. We have had two cases, seen late, with nonunion, but without aseptic necrosis of the head. In each of these we have done an open reduction, as far as possible, clearing the fracture line of the scar tissue, then introducing the nail, and have had satisfactory results. We have had two failures with this same procedure in cases where the heads were necrotic.

We have had hips satisfactorily reduced, nailed, and, as far as we could determine, satisfactorily recovered, that showed a marked change in the relation of the head on the neck, with protrusion of the nail occurring a year later. Obviously the interpretation of satisfactory union made radiographically was incorrect.

We have felt that these patients should be allowed to bear weight when the x-rays show

public health in permitting the practices followed by most lunch counters in this state."

Even if it were not for possible health significance and popular interest most people will agree that common decency should demand at least the removal of saliva and lipstick from glasses between uses.

One of the greatest difficulties encountered in the improvement of restaurant hygiene is the human element. Cooks, waiters, and waitresses work for low wages. There is a frequent turnover and new recruits receive little, if any, training. How are they to learn the principles of good hygiene? Does the busy eight-dollar-a-week waitress realize that she is endangering someone's health when she empties a used water glass just removed from a table and fills it for the next customer without stopping to wash it? Probably, it never occurs to her that anything more serious could happen than that the glass might not look clean to the customer. No doubt some of you have seen girls preparing salads stop to lick their fingers and go ahead with their work as if nothing happened. Ask a counterman to hand you four cups and he is more than likely to grasp four right side up in one hand by putting a finger in each cup. Then there is the soda clerk who mixes an overdose of chocolate drink and when he is in a spot where he thinks he is not seen, drinks the excess out of the mixer before serving the customer. We can always take for granted the food handler who leaves the toilet room without washing his or her hands. Fortunately, disease carrier control protects the public to a certain extent against such people. These are just a few of the things that happen and, knowing human nature as doctors must, you will agree they are going to continue to happen while the human element remains in the picture. However, such happenings can be minimized by intensive education and by making it easier through the use of proper equipment to do things the right way than to do them the dangerous way. Another protective weapon is to make critical operations visible for customer supervision in the way the cash register is used.

Aside from the personal element the next item most likely to affect health directly is the efficiency of washing and sterilizing dishes and glasses. It is on this important item that the Department is concentrating attention.

This problem usually has been handled in the easy way—that is, someone has said "there ought to be a law." After an "air-tight" but not necessarily practical law has

been passed and after perhaps a few conscientious operators have complied with the letter of the law whether or not they have accomplished results, we sit back and feel that the problem has been solved.

A study of the many varied state laws and municipal ordinances or regulations is illuminating. One quickly reaches the conclusion that many different and sometimes conflicting regulations cannot all be right. The principal fault of most of them is that they prescribe methods to be used rather than the results to be obtained. In an effort to require the use of "sure kill" methods—that is, to secure a close approach to surgical sterility—many of the methods are impractical. For example, some laws require so-called sterilization of utensils by soaking them in hot water at 170 or 180 F. or more for not less than two minutes. Most dishwashing machines on the market wash and disinfect dishes in between one or two minutes usually by spraying. Even with hand operation it is difficult to conceive that the busy operator will leave a basket of dishes in the rinse water for two minutes. We once asked an operator in a large city restaurant how long he left each basket of dishes in the hot rinse water. "About fifteen minutes, sub," was the reply. We then clocked this operator putting a basket full of glasses through in fifteen seconds flat.

In order first to understand the problem ourselves, our work was begun with field observations. Some of the things observed have been related. Two unsatisfactory methods of washing are much in evidence. One of these is the practice followed at many soda fountains and taverns of simply sloshing a soiled glass around in a tank full of cold or warm water of questionable cleanliness. The second method observed in some small restaurants is to wash the dishes in warm, soapy, and, generally, greasy water in some container, such as an old lard tub, then placing them upside down on a drainboard. Occasionally, the dishwasher will draw a saucepanful of water out of the warm water faucet and pour it over the outsides of the dishes as they are stacked for draining. Then they are dried with towels of questionable cleanliness. There are plenty of opportunities for hand contamination of such dishes before they reach the customers.

These field observations also revealed some obvious defects in the operation of dishwashing machines. For instance, where drip-regulated solution feed jars were used to maintain continually the concentration of deter-

RESTAURANT HYGIENE

WALTER D. TIEDEMAN, M.C.E., Albany, New York

IS RESTAURANT hygiene of any significance to health? What are the more important problems involved? Are present conditions bad and, if so, what methods are being, or can be used to improve sanitary conditions? Are these methods effective and efficient? Are present laws and regulations reasonable and, if not, how should they be modified? Are present enforcement methods reasonable and efficient? These are some of the questions that faced the New York State Department of Health in 1938 when attention was directed to the problem of restaurant hygiene by an amendment to the Public Health Law requiring the sterilization of utensils used in public eating and drinking places. This was closely followed by the adoption of a chapter of the Sanitary Code relating to restaurants. The law was further amended the following year at the Department's recommendation to require "disinfection" instead of "sterilization." Perhaps the answers to all of these questions are not yet known, but studies to date have uncovered some interesting, practical problems and what appear to be reasonable solutions.

As to the public health significance of restaurant hygiene, there is not enough incontrovertible evidence to mark it as an important problem. We must give some weight to the work of Lynch and Cummings¹ at the Port of Embarkation at Newport News during the World War when influenza was pandemic. Briefly, groups of soldiers aggregating about 33,000 used dishes washed by the individual mess kit method and other groups of about equal total used dishes washed collectively and rinsed in water at about boiling temperature. During a two weeks' period of observation approximately five times as many cases of influenza occurred among those using the individual mess kit method of washing as occurred among those who used boiled dishes. Investigators² have reported finding *Staphylococcus albus* and *aureus* and *Streptococcus viridans* on supposedly clean eating and drinking utensils in restaurant and beverage rooms. The same investigators report finding hemolytic streptococci in wash and rinse waters. How-

ever, we can find no reports of proved outbreaks of disease traced to utensils.

Regardless of scientific proof of health significance, the man on the street is convinced that restaurant hygiene affects his health directly and resents the unsatisfactory practices he observes from day to day in public eating places. We have observed a male patron at a busy cafeteria dip a paper napkin in his coffee, then use it to wash the rim of his cup, his knife, fork, and spoon and, finally, dry them carefully with the dry portion of the napkin. Then he felt safe to go ahead and eat.

To illustrate this further, a nurse in complaining about conditions at a five-and-ten-cent-store soda fountain says: "Three weeks ago I had a soda there, and the next day had a very bad sore throat which lasted a week. Yesterday my husband and I each had a soda there, and today he has a sore throat. While we were sitting at the counter, one of the waitresses was washing dishes in water with apparently no soap, and it could not have been very hot as there was no sign of steam from it. After 'washing' the dishes, glasses and spoons, the girl wrung out the dishcloth and, without rinsing the dishes, used the same dishcloth to wipe them, putting the spoons back in the tray from which they were to be used. Until then, I had not thought of any connection between the sodas and the sore throats, and there might not have been any, but with the prevalence of colds and grippe, it seems to me that a soda fountain should use a more sanitary method of washing dishes."

As another example, the president of a large milling concern writes: "For a long time now I have refrained entirely from patronizing drinking fountains and lunch counters in this state because of the inexcusably filthy way in which eating utensils are washed and dried after use for further servings. Such places are, potentially, spreaders of dangerous diseases. At some counters I have actually seen waiters rinse their hands in the same water as that in which eating utensils are supposed to be washed and then dry their hands and arms clear to the elbows with the towels used for drying such utensils. In many places—I am inclined to think in most places—there is not even a pretense at the use of hot water. In my opinion your Department is tolerating an indefensible menace to

¹Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 29, 1941.

²Chief, Bureau of Milk Sanitation, New York Department of Health.

public health in permitting the practices followed by most lunch counters in this state."

Even if it were not for possible health significance and popular interest most people will agree that common decency should demand at least the removal of saliva and lipstick from glasses between uses.

One of the greatest difficulties encountered in the improvement of restaurant hygiene is the human element. Cooks, waiters, and waitresses work for low wages. The principal fault of most of them is that they prescribe methods to be used rather than the results to be obtained. In an effort to require the use of "sure kill" methods—that is, to secure a close approach to surgical sterility—many of the methods are impractical. For example, some laws require so-called sterilization of utensils by soaking them in hot water at 170 or 180 F. or more for not less than two minutes. Most dishwashing machines on the market wash and disinfect dishes in between one or two minutes usually by spraying. Even with hand operation it is difficult to conceive that the busy operator will leave a basket of dishes in the rinse water for two minutes. We once asked an operator in a large city restaurant how long he left each basket of dishes in the hot rinse water. "About fifteen minutes, suh," was the reply. We then clocked this operator putting a basket full of glasses through in fifteen seconds flat.

In order first to understand the problem ourselves, our work was begun with field observations. Some of the things observed have been related. Two unsatisfactory methods of washing are much in evidence. One of these is the practice followed at many soda fountains and taverns of simply sloshing a soiled glass around in a tank full of cold or warm water of questionable cleanliness. The second method observed in some small restaurants is to wash the dishes in warm, soapy, and, generally, greasy water in some container, such as an old lard tub, then placing them upside down on a drainboard. Occasionally, the dishwasher will draw a saucepanful of water out of the warm water faucet and pour it over the outsides of the dishes as they are stacked for draining. Then they are dried with towels of questionable cleanliness. There are plenty of opportunities for hand contamination of such dishes before they reach the customers.

These field observations also revealed some obvious defects in the operation of dishwashing machines. For instance, where drip-regulated solution feed jars were used to maintain continually the concentration of deter-

gent or dishwashing compound in the wash water, these were almost invariably found to be clogged. Satisfactory types are available in which the flow control throttle valve is on the fresh water rather than the solution. In a common type of glass washer the rinse water is sprayed through a single perforated pipe at the back. If the tray of glasses is pushed out over this pipe very slowly the glasses are fairly well rinsed. However, the natural thing is for operators to push them out quickly. In another machine there was sufficient headroom to introduce one basket of glasses on top of another for washing. In a busy five and ten cent store we found an operator putting the baskets in two deep with never a thought as to how the lower sprays were to reach the upper glasses or the upper sprays to reach the lower glasses.

Other more serious and more intricate defects were discovered. Some of the simpler machines were doing better work than the more complex ones. With a view to exploring the whole dishwashing machine problem and bringing defects to the attention of the manufacturers for needed improvements, a committee of the American Public Health Association made a study of machines in 1941.

Most operators are willing to admit that they are using really hot water for disinfection of dishes and glasses; in fact, they will say that it is practically boiling. However, the thermometer frequently tells a different tale. It is not practical to carry the temperature of hot water at 180 F. or higher in a circulating system serving a building. Metals other than monel metal used in storage tanks and pipes deteriorate rapidly under temperatures as high as this. Also, people using hot water for other purposes may scald themselves. There are two possibilities for securing the hot water required. One is to install a booster heater designed for the purpose of taking water from the circulating hot-water system and raising it to 180 F. or more in the quantity required for rinsing dishes. The other possibility is to rinse the dishes by immersion in hot water, in which case an open, thermostatically regulated gas burner is placed under the tank of rinse water to maintain the required temperature. Laboratory studies of dishwashing have been conducted under the supervision of Mr. F. W. Gilcreas of our Division of Laboratories and Research, while the field studies were in progress. The so-called swab rinse technic has been used for determining whether or not dishes and glasses have been properly washed and disinfected. Briefly,

a sterilized cotton swab on stiff wire is soaked in sterilized, buffered distilled water and used to swab the rims of cups and glasses and 4-square-inch areas of dishes. This may also be used to swab the bowls of spoons and the tines of forks. At the laboratory the swabs in the buffered distilled water are placed in a shaking machine and portions of the water are then plated according to standard methods. After many tests had been made a study of the results indicates that a bacteria count of 100 or less per utensil may be considered as satisfactory disinfection. Results also indicate that it is reasonable to expect these rinse samples to be free of bacilli of the coliform group.

Early in this work it became apparent that the washing operation deserved much more consideration than had heretofore been given it. For instance, in testing the efficiency of certain so-called sterilizing processes by laboratory test using hemolytic streptococci of human origin artificially applied to glasses, it developed that the controls subjected only to good washing and rinsing were free from the pathogenic organisms. Apparently, they had been removed mechanically without the aid of disinfection. Further tests using coliform organisms showed that disinfection by chlorine or ultraviolet irradiation were ineffective when not preceded by effective washing. This is not stated with a view to minimizing the value of disinfection but simply to point out the importance of good washing and rinsing.

It has been apparent from the start that the properties of detergents bear an important relationship to the effectiveness of the results obtained in washing utensils. Some of the ingredients of detergents which improve their effectiveness are expensive. It follows that if detergents are bought and sold simply on a price basis most of the detergents used are going to be the cheaper and ineffective ones. For this reason it appeared to be a primary objective of work in this field to test and classify detergents. It is to be expected that the detergent or washing compound should (1) emulsify food fats; (2) flocculate other food solids; (3) wet glass, china, and metal surfaces readily and consequently rinse freely; and (4) suspend calcium or other minerals in the water. If separate tests of detergents were made for each of these properties, the problem of integrating results of the various tests into a coherent whole would be a difficult one.

The Division of Laboratories and Research of the Department also has been testing de-

tergents by means of a combined test that is expected to result in a broad classification of the detergents tested which will serve as a practical guide for operators. In principle, this test consists of dipping clean microscope slides in a fluid soiling material made up of an assortment of food fats and such substances as flour, soybean meal, spinach, and milk. This is dried on the slide in an oven, and the slide is then washed in a 1.3 per cent solution of the detergent to be tested, is maintained at a standard temperature in a standard laboratory mechanical washer for two minutes, and is then rinsed by a similarly standardized method. After the washed and rinsed slide is dried, it is dipped in activated carbon to accentuate the remaining film. The excess carbon is removed by suction and the amount of light passing through the slide is compared with the amount passing through a clean slide similarly treated with activated carbon. The comparison is made by means of an electric eye, giving a scale reading that is used as an index of effective detergency. Tests are being made with water of different hardness and with rinse water at different temperatures. It is believed that work of this kind, while time-consuming in itself, will in the long run do more to advance the cause of cleanliness in food utensils than police work in the enforcement of arbitrary rules.

Heretofore, most efforts at improving restaurant hygiene have been directed along the line of specifying so-called methods of sterilization to be followed. Ultraviolet irradiation, chlorine, hot air, steam, and hot water are among the agents used. Present work included studies of such methods.

When the glasses are absolutely clean and dry, exposure to ultraviolet light is found to be beneficial. However, ultraviolet rays do not penetrate glass or greasy films, and there is a tendency for the rays to be deflected by globules of water.

There are many practical defects to stand in the way of using chlorine effectively as a disinfectant. Our laboratory tests indicate that if all the greasy film is not removed in the washing process the chlorine is ineffective. If all the film is removed, it is quite likely that practically all the bacteria have been removed mechanically. Experience has shown that operators will not leave glasses or dishes in chlorine solutions for the two minutes required for it to take effect. If they are allowed to rinse the residual chlorine off, it is generally done before the chlorine has had time to take effect. Otherwise, traces of

chlorine remain on the rims of glasses and produce an objectionable taste.

There appears to be a tendency for wetting agents used in detergents to have bactericidal properties. Furthermore, some investigators³ have reported favorably upon the use of industrial zephiran or roccal containing high molecular alkyl-dimethyl-benzyl-ammonium chloride as a chemical disinfectant for utensils. Our laboratory has not as yet tested this product. Our practice is to proceed slowly with new products until there is ample confirmation of results from unbiased sources. However, there appears to be a good possibility to secure a good disinfectant in this field for tavern and soda-fountain use.

Hot air should be a satisfactory disinfecting agent, provided sufficient time is allowed for the utensils to take on the heat. However, in one hot-air sterilizer tested, the manufacturer's recommendation was to keep the regulator set at 250 F. and leave the glasses in for five minutes. In checking temperatures after inserting a full tray of heavy glasses it developed that a temperature of only 99 F. had been reached at the end of a five-minute period. It took sixty-five minutes for the temperature to get back to 250 F.

Steam should be an effective sterilizing agent if properly applied. However, it is necessary to confine the steam in a cabinet and to provide a cold-air release to prevent a blanket of cold air from protecting the utensils from the steam.

The method most frequently found to be producing good results was immersion of utensils in hot water thermostatically maintained at 170 F. or higher. This treatment has the added advantage of providing an additional rinse with water that should be free from harmful bacteria because of the temperature. Dishes and glasses so treated will dry rapidly without toweling.

Properly designed wire baskets are essential for the immersion of dishes in hot water, as well as for the storage of glasses and cups. When immersing cups and glasses it is important that they be in such position that no air will be trapped in them, thus preventing the hot water from coming in contact with all of the inner surfaces. The glasses should be placed upside down in the rack so that they will be grasped by the bottom when removed, and the cups with the handles up so that they will be grasped by the handles instead of by the rims. This prevents finger contamination of surfaces with which the mouth or beverage may come in contact. A sufficient

number of wire racks should be provided in which to store glasses and cups until they are used. These racks are made to stack one on the other.

The observation that visually clean surfaces were usually free from bacteria led the Department to encourage the development of a device for determining whether or not glasses are visually clean. The General Electric Company has developed such a device for examining glasses. The observer gets a view of the glass under such light conditions similar to those in dark-field illumination and any film on the glass is visible. The use of a device like this should cut down the amount of laboratory work needed, since health officers will require that operators first get the glasses visually clean before they have laboratory tests made to determine freedom from bacteria.

The results of studies have convinced us that the most practical type of regulation is one setting a bacteriologic standard to be attained in the washing and disinfection of dishes, permitting the operator to select and use the method of his choice. Furthermore the most effective enforcement procedure is to check by visual and laboratory tests the results being obtained, followed by efforts to correct unsatisfactory conditions by persuasion if possible, but by coercion if necessary.

The New York State Sanitary Code now provides that "all eating, drinking, and cooking utensils shall be so cleansed and disinfected as to be free from bacilli of the coliform group and to have a total bacteria count of not more than 100 per utensil as determined by test in a laboratory approved for the purpose by the state commissioner of health." In approving the laboratories the commissioner prescribes the technic to be followed in making tests.

It has taken considerable time to build up the ground work for what we expect to be a good program in restaurant hygiene. However, once the underlying principles are generally understood and inexpensive, adequate equipment is available to make it easy to wash and disinfect dishes and glasses effectively, progress should be rapid.

Discussion

Dr. Paul B. Brooks, Albany, New York—Mr.

Tiedeman has pointed to the fact that the evidence of danger from the use of inadequately cleaned dishes and utensils in public eating places is rather limited. The fact is that it is largely circumstantial. We do not find records of epidemics traced to dirty dishes as we do to water, milk, and other foods and for reasons that are rather apparent when you give the matter a little thought.

The contaminated milk, for example, is consumed by a number of people at the same time and they develop symptoms of infection at about the same time. The discovery that the milk was the thing used in common gives the clue, and the milkman has a list of his customers. Eventually, the laboratory may be able to demonstrate the contamination in the milk. But when a customer with infected mouth secretions contaminates the edge of a glass (and I believe the drinking glasses probably are the greatest factor in the spread of infection), the next customer may be the only one exposed to the infection. He may develop scarlet fever or influenza or something else but there is practically no possibility of tracing the source of his infection.

We know that we have many sporadic cases of diseases transmissible through mouth secretions, and it is quite possible—in fact I would say rather probable—that some of them come from dirty eating and drinking utensils. I doubt, however, if the number is relatively great. The contaminated drinking glass might be compared to the clandestine prostitute; it is a source of danger but the number of people it is likely to infect is limited. So I believe the problem is, at least in part, one of esthetics—municipal housekeeping.

In the Department we have gotten in the habit of referring to the restaurant hygiene program as the "dishwashing" program. We have used this term facetiously but it is not so far off. As Mr. Tiedeman has brought out, the practical studies that have been made have demonstrated that practically all that is needed to get the degree of bacterial reduction set up as the standard is a good washing job—washing with hot water and soap or some other detergent, followed by rinsing with hot water.

I heard, a while ago, of a city health officer who was not pushing this "dishwashing" matter so far as the drinking places were concerned because the local ABC Board was opposed to it. They said these places had "trouble enough now." I recently heard of a bartender who made a vociferous protest because a customer questioned the adequacy of rinsing his glasses in cold water. If general reconstruction of equipment had been required, with the use of chlorine solutions, etc., as many at first thought was necessary, there might be some grounds for sympathy and protests. But I can see no reason why a place unwilling or unable to do an ordinarily good job of dishwashing should expect to be permitted

to impose on the public, regardless of the possible danger. If it cannot provide soap and hot water and someone capable of applying them, it should not be in the business.

Our practical problem, at the moment, is that of enforcement. A city of from 50,000 to 75,000 people, for example, has several hundred eating and drinking places. It has a limited inspection force and limited laboratory service available for this type of work. The smaller the community, the more limited the facilities, generally speaking. It would be unwise to take an inspector off from milk or other important work for any long period. To take swabbings for laboratory examinations in all places, with the amount of information required by the laboratory, would involve an amount of time and effort that would be prohibitive. So I believe the best procedure is to educate the public to expect and demand cleanliness and to do its own in-

specting. Our motion picture "Twixt the Cup and the Lip" represents an effort in this direction. The official inspectors, I believe (and I am quite sure Mr. Tiedeman agrees with me), should depend largely on visual inspections to see if proper facilities are provided and used; these should be followed up with the laboratory tests on the unsatisfactory places. If they get too recalcitrant, they should be taken to court. Westchester County recently reported a successful prosecution where the laboratory test was accepted as evidence. Sentence was suspended only because, before the case came to trial, the defendant had provided necessary equipment.

For some reason this restaurant hygiene program seems to have a special popular appeal. In allotting our time and effort relative values should be considered, but it is a good idea to "strike while the iron is hot."

MEETING—AMERICAN SOCIETY OF ANESTHETISTS, INC.

The regular meeting of the American Society of Anesthetists, Inc., was held in the Squibb Auditorium, 745 Fifth Avenue, New York City, on April 9 at 7:30 P.M. The scientific session was as follows:

1. "Possibilities and Limitations of Barbiturates in Anesthesia as Suggested by Experimental Work"
Henry K. Beecher, M.D., Door Professor of Research in Anesthesia, Harvard Medical School; Anesthetist-in-Chief, Massachusetts General Hospital, Boston
Discussant: Alfred Gilman, Ph.D., Assistant Professor of Pharmacology and Toxicology, Yale University School of Medicine, New Haven, Connecticut
2. "Refrigeration Anesthesia for Limb Operation"
Frederick M. Allen, M.D., Professor, Department of Internal Medicine, Polyclinic Hospital, New York City
Discussant: Lyman W. Crossman, M.D., Chief Surgeon, City Hospital, New York City
3. "Asphyxial Resuscitation—The Phenomenon and Its Mechanism"
Samuel A. Thompson, M.D., F.A.C.S., Associate Professor of Surgery, New York Medical College, New York City
"Comparison of Methods of Resuscitation"
George L. Birnbaum, M.D., F.A.C.S., Lecturer in Surgery, New York Medical College, New York City
Discussant: B. B. Sankey, M.D., Anesthetist, Huron Road Hospital, East Cleveland, Ohio

WHAT ONE SCHOOL DOES FOR GOOD HEALTH

The entire program of the Community School is built around the principle that "health must come first."

"Our children have from 2 to 2½ hours a day out-of-doors. We have a play period before school, in the middle of the morning, for half an hour before lunch, and for 45 minutes after school.

"Our children are served a hot lunch at school, the menus being checked by our school physician, Dr. Hugh McCulloch. Nine children and a teacher sit at a table. We don't talk about the right food—we serve it and eat it. The younger children have from 40 minutes to an hour of rest on cots after lunch. The older children have shop, art, music, or rest on cots if they need it.

"Fruit is served at school after the afternoon play period, so that children will not stop at the corner drug store.

"We feel that posture consists of good nutrition, plenty of big muscle activity, and joy in work, so we don't do anything with posture exercises as such, but we do all we can to make good posture possible.

"The follow-up of eye tests and physical examinations is very careful and thorough. The parent is contacted directly and reports back to the school what the child's own physician finds to be true. A record of all his information is kept on file. Children and teachers with colds are not allowed to be in school."

Community School, St. Louis, Mo., Federal Security Agency, U. S. Office of Education, Circular No. 191, p. 13.

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL
AND HOSPITAL, COLUMBIA UNIVERSITY

Date: February 17, 1942

Presiding: Dr. Irving S. Wright

History (Case J 61838)

DR. ROBERT McGRATH: This patient was a 41-year-old white man who was admitted to the New York Post-Graduate Hospital complaining of cough and fever of four months' duration. A sudden chill, followed by a rise in temperature to 104 F., and pain in the right side of the chest marked the onset of his illness. Strapping of the chest gave little relief. In a few days a nonproductive cough developed and he gradually improved. The patient, however, never regained his former good health and lost considerable weight. An x-ray of the chest made two months prior to admission indicated the presence of an unresolved pneumonia. One month prior to admission, he had a bout of fever and a severe chill for which he was admitted to another institution. There an x-ray examination of the chest revealed "extensive changes" in his right lung. He showed improvement after one week and was discharged. Six days before admission to the Post-Graduate Hospital the patient had an hemoptysis of 10 ounces of blood which was followed by further hemoptyses of smaller volumes. Weight loss up to this time was 16 pounds. Prior to this illness the patient denied having a chronic cough. There was an episode of questionable hematuria two years before admission.

On physical examination the patient was thin, pale, and looked seriously ill. Temperature was 100.8 F., pulse 100 per minute, and respiratory rate 20 per minute. The tongue was coated. The buccal membranes had many small, white areas with superficial ulcerations. The teeth were in poor condition. Dullness, fine moist rales, and diminished breath sounds were noted at the right base posteriorly. The apex beat was forceful and located in the fifth interspace at the nipple line. Moderately loud apical and basal systolic murmurs were heard. The apical murmur was transmitted to the axilla. Blood pressure was 110/70 mm. of Hg. Examina-

tion of the abdomen and rectum was negative. Neurologic examination revealed no significant findings.

Laboratory Data.—Urinalysis: specific gravity, 1.020, very faint trace of protein, negative for sugar and acetone; microscopic—10 to 12 white blood cells with occasional clumps. The erythrocytes numbered 4,010,000 per cubic mm. There were 6,800 leukocytes per cubic mm. and a differential count revealed 59 per cent neutrophils, 31 per cent lymphocytes, 5 per cent monocytes, and 5 per cent eosinophiles. Secretion from the right bronchus obtained through a bronchoscope was reported negative for tumor cells. Cultures showed a few colonies of green streptococci. Sputum examinations on several occasions were negative for tubercle bacilli and tumor cells.

While in the hospital, the patient continued to run a febrile course. Bronchoscopy revealed no bronchial obstruction. Therapy with sulfadiazine resulted in only slight improvement. Repeated x-ray examinations of the chest showed an increase of the infiltration in the right lower lobe progressing to atelectasis of the right lower lobe accompanied by a moderate exudate. A punch biopsy of the involved area done at the level of the ninth interspace was negative for tumor cells. A right pneumothorax was induced on the twenty-fourth day of hospitalization and was maintained by weekly injections of about 250 cc. of air. An exploratory thoracotomy was performed on the thirty-seventh day of hospitalization and sections of the 5th, 6th, and 7th ribs on the right side were removed. The right lower lobe was adherent to the posterior chest wall. No enlarged nodes were noted and the wound was closed. Following operation, bilateral bronchopneumonia developed from which the patient never rallied.

Discussion

DR. BENJAMIN I. ASHE: I am going to make my discussion as brief as possible so that we may have sufficient time for Dr. Richter's presentation.

We have a case of recurrent pneumonia with

complications, which in itself would make one suspect bronchiectasis or a malignancy. This might be all there is to the case. I should like to make one diagnosis that will cover all these symptoms including the record of hematuria. The essential picture is that of a young man who had right pleural inflammation with thickening, a mass in the right lower lobe of the lung, and hematuria two years previously.

We have physical signs suggesting possible malignancy of the lung and the x-rays make this appear more likely. I do not think that the primary lesion is in the lungs but rather that this is a case of hypernephroma with pulmonary metastasis. There was thought to be hematuria two years ago but otherwise renal function was normal. Hypernephromata occur more commonly in men and are frequently the origin of pulmonary metastases. Patients with hypernephroma may have a prolonged history of dyspnea usually associated with hematuria and good renal function. Because of the lack of renal signs and symptoms found in these cases, they are usually sent to the cardiac clinic because of the dyspnea or to the chest clinic because of the prominent chest symptoms. Sometimes they are even sent away to a tuberculosis sanatorium for several months.

Dr. Ashe's Diagnoses

Multiple attacks of pneumonia with bronchiectasis possibly secondary to hypernephroma with metastasis to lung. Bronchopneumonia.

DR. ALFRED LILIENFELD: Would you say then that the cough, dyspnea, and hemoptysis were all secondary to the hypernephroma?

DR. ASHE: In the last few years I have seen 4 cases presenting a diagnosis of hypernephroma—one a sixteen-year-old boy who had marked renal symptoms and cough; one who had dyspnea, a very large kidney, and an elevated diaphragm; one who had a cough for a long time; and one, a hospital superintendent, had chronic bronchitis. As you see, in all these cases the first signs that something was wrong occurred in the lungs and were in all 4 cases due to pulmonary metastases. Other than hematuria, there are very few renal signs with this disease. In cases of hypernephroma look for signs elsewhere, particularly in the lungs and bones.

DR. JAMES FLEXNER: How would you rule out bronchogenic carcinoma?

DR. ASHE: Bronchogenic carcinoma usually occurs in the upper part of the bronchus.

The bronchoscopic findings were also against bronchogenic carcinoma. Several cases of bronchogenic carcinoma which I have recently seen showed clubbing of the fingers quite early.

DR. WRIGHT: Any other diagnoses?

DR. VINCENT LARKIN: Lung abscess secondary to pneumonia.

DR. FLEXNER: Bronchogenic carcinoma.

DR. MAURICE N. RICHTER: What was the clinical diagnosis?

DR. WRIGHT: The clinical impression was carcinoma of the right lower lobe of the lung.

Pathology

DR. MAURICE N. RICHTER: I am not going into a discussion of hypernephroma because it was not present. The principal lesion is in the right lower lobe. Here, there is an abscess cavity 3 cm. in diameter, on the inner surface of which is a thin layer of fibrino-purulent material. The cavity communicates with one of the medium-sized bronchi. Around it is a zone of light gray, fibrotic material. There are small inflammatory areas in other parts of both lungs, often in relation to bronchi, which show distinct dilatation in all lobes. There are about 450 cc. of purulent, blood-tinged exudate in the right pleural cavity and about 200 cc. in the left. There are adhesions over the right lower lobe.

There is marked thickening and calcification of both mitral and aortic valves, producing stenosis at both orifices such as is caused by rheumatic fever.

An interesting finding, which has no bearing on the clinical aspects of the case, is a tumor in the medulla of the adrenal gland. The tumor of the adrenal proved on section to be a ganglioneuroma.

Sections through the abscess cavity in the right lower lobe show it to be merely an abscess cavity and not a tumor mass that has degenerated. Around the abscess cavity and in other parts of the lungs are some areas of inflammation.

With regard to the lung abscess, it is of interest to recall an article in the *Journal of Thoracic Surgery*¹ in which 4 cases were reported of inflammatory conditions in the lungs which simulated pleural tumors. In some ways I think these cases were similar to the one we have here. The cases appeared under other clinical diagnoses, including carcinoma of the lungs. An interesting feature of some of their cases was the fact that they also were

¹ Freedlander, S. O., and Wolpaw, S. E., Chronic Inflammatory Lesions of the Lung Simulating Bronchogenic Carcinoma, *J. Thoracic Surg.* 9: 530 (1940).

unable to differentiate between a lung abscess and other conditions and a carcinoma of the lung even during operation.

Pathological Diagnosis

Bronchiectasis, bilateral.
Abscess of lung, right lower lobe.
Lobular pneumonia, bilateral.
Operation—thoracotomy.
Rheumatic endocarditis of mitral and aortic valves, healed.

Mitral and aortic stenosis and regurgitation.
Chronic passive congestion of lungs and spleen.

Hydrothorax, bilateral.
Ganglioneuroma of adrenal gland, left.

Annual Meeting Prizes

At the 1942 Annual Meeting of the Medical Society of the State of New York two essayists received prizes and certain scientific exhibitors were given awards for merit.

The *Lucien Howe* prize went to Dr. Jacob Goldsmith, of New York, for his essay entitled "Original Studies on the Internal Dynamics of the Intracapsular Cataract Extraction."

The *Merrit H. Cash* prize went to Dr. Emanuel Goldberger, of the Bronx, for his essay entitled "The Use and Advantage of Augmented Unipolar Extremity Leads in the Electrocardiographic Diagnosis of Myocardial Infarction (Coronary Thrombosis) and Acute Coronary Insufficiency."

Among the many scientific exhibits the awards were as follows:

RESEARCH CLASS

First Award: Jacob Goldsmith, M.D., Mount Sinai Hospital, New York—"Recent Experimental Studies in Cataract Extraction."

Second Award: Hollis K. Russell, M.D., Robert C. Page, M.D., Zacharias Bercovitz, M.D., New York Post-Graduate Medical School and Hospital and St. Agnes Hospital, White Plains—"Simplified Prothrombin Clotting Time Determinations, Macro and Micro Methods."

Honorable Mention: James L. McCartney, M.D., and J. de Carvajal-Forero, B.S.S., Ph.B., roentgenologist, New York—"Radiography of Soft Tissues by Monochromatic X-Radiation."

CLINICAL APPLICATION

First Award: Lester J. Unger, M.D., and New York Post-Graduate Medical School and Hospital—"Blood Banks—Plasma Preparation and Storage."

Second Award: J. Eastman Sheehan, M.D., and New York Polyclinic Medical School and Hospital—"Plastic Reparative Surgery."

Honorable Mention: George Miller MacKee, M.D.; Anthony C. Cipollaro, M.D.; Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University, New York—"Cutaneous Manifestations of Tuberculosis."

SPECIAL CLASS

Medical Department of the United States Navy, Rear Admiral Harold W. Smith (MC) USN—"Medical Department of the United States Navy."

Medical Preparedness

Appointments in the Navy Open to Medical Students

APPPLICANTS for appointments as Acting Assistant Surgeon (intern) are required to be citizens of the United States, to have completed at least three years of medical education in a class A medical school, and to meet the physical and other requirements as set forth in the circular of information for appointment in the Medical Corps of the Navy. Circulars are obtainable upon request to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., or to the Director or Senior Medical Officer of Naval Officer Procurement, 33 Pine Street, New York City. Examinations for appointment as Acting Assistant Surgeon (intern) are held each year, usually during the months of June, October, and January, at all of the larger Naval hospitals and at the Naval Medical Center, Washington, D. C. Successful candidates from these examinations receive their appointments following the successful completion of their medical education.

Appointments as Acting Assistant Surgeon (intern) are for eighteen months' duration. An Acting Assistant Surgeon, after one year of Naval internship may apply for and take the

examination for Assistant Surgeon, U. S. Navy. Acting Assistant Surgeons (interns) serve a rotating internship in a Naval hospital accredited for intern training by the Council on Medical Education and Hospitals of the American Medical Association.

If an Acting Assistant Surgeon does not desire to qualify for appointment as Assistant Surgeon, U. S. Navy, after completion of one year of intern training, he may apply for appointment as Lieutenant (junior grade) MC-V(G), U. S. Naval Reserve, and continue on active duty as such during the present emergency.

Completed application forms, together with the required data, must be received in the Bureau of Medicine and Surgery at least three weeks prior to the date of examination.

Assistant Surgeons and Acting Assistant Surgeons while on active duty receive the pay and allowances of a Lieutenant (jg), which for officers without dependents is \$2,699 per year, and for officers with dependents is \$3,158 per year. On reporting for active duty, a uniform allowance of \$250 is granted.

Appointments in the Naval Reserve Open to Medical and Dental Students

Medical and dental students, premedical and preidental students are eligible for commissions as Ensigns, Hospital Corps. Volunteer Probationary, Class H-V(P) USNR. Age limits 19 to 30 years.

Requirements

Medical students of all classes of class A medical schools and premedical students who have been accepted as first-year students in medical schools accredited as class A by the Council on Medical Education and Hospitals of the American Medical Association.

Dental students of all classes of accredited dental schools and preidental students who have been accepted as first-year students in dental schools accredited as class A by the American Dental Association.

If the physical examination is made at any other activity than the Office of Naval Officer Procurement, 33 Pine Street, New York City, a report of it is forwarded to that office. Having passed the prescribed physical examination, application papers and instructions for appointment as Ensign H-V(P) USNR will be issued to candidates by the Director of Naval Officer Procurement.

Ensigns H-V(P) USNR upon graduation will be reappointed Lieutenants (junior grade), Medi-

cal Corps or Dental Corps, USNR, and those of the Medical Corps are not considered as available for active duty until the completion of at least a year's internship in an accredited hospital for intern training.

A statement from the Dean that a premedical or preidental student has been accepted for enrollment in the first coming semester, and for those already enrolled in medical or dental schools that the student is in good standing, is required.

Candidates are required to pass a physical examination by a Naval Medical Officer as the initial procedure in making an application. The physical examination may be made at any activity where a Naval Medical Officer is available: Office of Naval Officer Procurement, 33 Pine Street, New York City; Navy Recruiting Station, Albany, Buffalo, and Rochester, N. Y.; or New Haven, Conn.; and Marine Recruiting Station, Syracuse, N. Y.

Uniforms are not prescribed until ordered to active duty, when a uniform allowance of \$250 is granted. The pay for officers of the rank of Lieutenant (jg), USNR, when on active duty, is \$2,699 per year (without dependents), and \$3,158 per year (with dependents). Ten per cent increase in base pay is provided when an officer is on sea duty.

Appointment in the Naval Reserve Open to Medical Doctors

Volunteer General Service Class: An applicant must be a graduate of a medical school listed as class A by the Council on Medical Education and Hospitals of the American Medical Association

to be commissioned; otherwise he must demonstrate his professional qualifications by such written, oral, or practical examinations as may be prescribed by the Bureau of Medicine and

Surgery. An applicant must not be over 35 years of age, and must have been a citizen of the United States for ten years, and if a year's internship in an accredited hospital for intern training is not completed, active duty orders will be deferred until that date. The only rank open to applicants for Volunteer General Service Class is Lieutenant—Junior Grade.

Volunteer Special Service Class: An applicant, in addition to the professional qualifications for eligibility for Volunteer General Service Class, must demonstrate that he is a well-trained specialist in his field, by his training in his specialty, hospital and teaching positions, memberships and fellowships in medical or surgical associations, and contributions to medical literature. An applicant must be under 50 years of age and a citizen of the United States for ten years.

The rank based on age requirements for which one may apply is as follows:

Lieutenant Commander 37 to 49 years of age
Lieutenant—Senior Grade 33 to 44 years of age
Lieutenant—Junior Grade 27 to 38 years of age

Uniforms are not prescribed until ordered to active duty, when a uniform allowance of \$250 is granted. The pay for the officers of the rank of Lieutenant Commander, when on active duty, is \$3,936 per year (without dependents), \$4,348 per year (with dependents). Rank of Lieutenant is \$3,336 per year (without dependents) and \$3,792 per year (with dependents). Rank of Lieutenant—Junior Grade is \$2,699 per year (without dependents) and \$3,158 per year (with dependents). There is an increase in base

pay after each three-year period of service. Ten per cent increase in base pay is provided when an officer is on sea duty. Expense for traveling under orders at the rate of eight cents per mile is allowed. Officers and their dependents are eligible for free medical and hospital care in the Navy.

Candidates are required to pass a physical examination by a Naval Medical Officer as the initial procedure in making an application. The physical examination may be made at any activity where a Naval Medical Officer is available: Office of Naval Officer Procurement, 33 Pine Street, New York City; Navy Recruiting Station, Albany, Buffalo, and Rochester, N. Y.; or New Haven, Conn.; and Marine Recruiting Station, Syracuse, N. Y.

Having passed the prescribed physical examination and the report received in the Office of Naval Officer Procurement, application papers and instructions will be mailed to the candidate. When application papers are received in the Office of Naval Officer Procurement and found to be complete for forwarding to the Navy Department, Washington, D. C., a letter will be written to the applicant's Selective Service Board requesting deferment until final action is taken.

It is not necessary for candidates for commissions in the Navy Medical Corps Reserve to be cleared through the Procurement and Assignment Service before filing their applications.

If not convenient to come in for a personal interview, inquiries may be made by writing to the Director or Senior Medical Officer, Naval Officer Procurement, 33 Pine Street, New York City.

A REGIONAL MATERNAL AND CHILD WELFARE TEACHING DAY

... will be held at the Westchester Country Club, in Rye, New York, on Wednesday, May 20, under the auspices of Regional Maternal and Child Welfare Committees of Dutchess, Orange, Putnam, Rockland, and Westchester county medical societies; Division of Maternity, Infancy, and Child Hygiene of the State Department of Health; and the Medical Society of the State of New York.

The meeting will be called to order at 2:30 P.M. by Julian Hawthorne, M.D., regional chairman in obstetrics, Maternal and Child Welfare Committee of the Medical Society of the State of New York.

Complications of Pregnancy: Heart Disease, Tuberculosis, and Diabetes, by Vincent P. Mazzola, M.D., instructor in obstetrics and gynecology, Long Island College of Medicine, Brooklyn.

Newborn Apnea and Resuscitation: Causes, Treatment, After-Effects on Child, by Charles A. Weymuller, M.D., professor of pediatrics, Long Island College of Medicine, Brooklyn.

Procedure for Study of Maternal Deaths, by Charles A. Gordon, M.D., professor of clinical obstetrics and gynecology, Long Island College of Medicine, and director, obstetrics and gynecology, Kings County Hospital, Brooklyn.

Following each of these papers there will be a period for discussion.

A dinner will be held at 6:45 P.M. preceded by a social hour and cocktails at six o'clock. Dinner will be served at the Westchester Country Club. The price of the dinner is \$2.25 and dress is informal. The sponsoring agencies are very anxious to know how many plan to attend the sessions and the dinner. Dinner reservations must be made not later than May 18. Address communications to Julian Hawthorne, M.D., 131 Purchase Street, Rye, New York.

The chairman of the evening program is Reginald A. Higgons, M.D., regional chairman in pediatrics, Maternal and Child Welfare Committee of the Medical Society of the State of New York.

Importance of RH Factor in the Blood: Its Effects on Transfusion Reactions, Erythroblastosis, Miscarriages and Stillbirths, by Philip Levine, M.D., bacteriologist and serologist, Newark Beth Israel Hospital, Newark, New Jersey.

Chemotherapy, by William E. Studdiford, M.D., professor of obstetrics and gynecology, New York University College of Medicine, New York City.

CAMP
TRADE MARK

SACRO-ILIAC SUPPORTS

Front and back views of sacro-iliac support for patient of intermediate type-of-build. Single adjustment brings the belt well down around the pelvis, hooking buckles in front allow fractional adjustment. The belt is lined with flannel and comes equipped with permeal straps.

IN the conservative treatment of conditions affecting the sacro-iliac joint, such as sacro-iliac sprain or arthritis of the joint, Camp sacro-iliac supports, when prescribed by physicians and surgeons have proved valuable adjuncts.

Camp supports are easily applied and thus facilitate removal for heat, massage and other physical therapy routine.

Among the sacro-iliac supports for men, provision is made by Camp for all types of build and for many sizes in each type. Firm fabrics are used in their construction; they may be applied with or without pads as desired.

Camp supports are available at most surgical supply dealers from coast to coast where Camp-trained fitters qualify to meet the patients' requirements as recommended or prescribed by physicians and surgeons.

Accident and Health Insurance

A FEW weeks ago an interesting decision was handed down by the Appellate Division of the Supreme Court of this State, in which the subject under consideration was the interpretation of a policy of accident and health insurance held by a practicing physician.*

The plaintiff was a middle-aged physician whose practice was about 90 per cent surgery and the rest general medicine. On February 9, 1940, while walking from his garage to his house carrying two medical bags, he slipped on some ice and fell backward. He felt pain in the right arm and shoulder and in his breast and chest. When he was assisted to his feet he concluded the shoulder had been dislocated, but that it had gone back into place. His condition was painful during the night and he had difficulty in breathing. He stayed in bed the next morning and the next evening went to another physician for x-rays which were negative for fracture.

Plaintiff did not consult any other physician until February 26 when, because of continuance of pain in the chest, he had another x-ray which was negative. The doctor who had taken the x-rays suggested an electrocardiogram which led to a diagnosis of a cardiac ailment.

The day after the accident the plaintiff attended three of his own patients and subsequently in the next two weeks made a few other professional visits. He also at the end of February went to his office and prepared reports on certain of his cases.

The plaintiff carried a combined accident and health policy insuring him against loss "resulting directly and independently of all other causes, from bodily injuries . . . solely through external, violent and accidental means, and against disability from disease." The policy provided it should, first, cover accidental death, second, indemnity by weekly payments against total disability or partial disability, and, third, cover disability caused by disease. The insurance company had undertaken to pay \$50 for not more than 200 weeks of continuous disability "if such injuries shall wholly and continuously disable the insured from the date of the accident and prevent him from performing any and every duty pertaining to his occupation." The policy contained provisions that for disability caused by disease, the assured should receive \$50 weekly for house confinement and \$25 weekly for disability described as nonhouse confinement.

On March 1, 1940, plaintiff filed a notice of disability with the company, describing his condition as "luxation of right shoulder joint, traumatic neuritis, left ventricular preponderance and enlargement of the heart; that the injury to his shoulder occurred on February 9 and the heart condition on February 26, and that he had been confined to the house for twelve days, with eight days of nonhouse confinement,

and that the date he first returned to work was 'partial on different dates.'" He later filed further forms regarding his disability which showed only partial resumption of any of his professional work for a time after the accident, and showed that from that time on he had done no surgical work and had taken on no new cases. He established, and it was not at any time disputed by the insurance company, that from April 1, 1940, he was totally disabled.

The plaintiff brought suit against the company on two causes of action, the first to recover \$50 a week from April 1, 1940, for total disability caused by a dislocated shoulder, coronary thrombosis, and traumatic neuritis, resulting from the accident; and second, to recover for periods of disability after April 1, 1940, due to the disease of coronary thrombosis and neuritis, which it was alleged had its onset prior to that date.

The second of the two causes of action was discontinued upon the trial by the physician who elected to stand upon his cause of action to recover indemnity for disability through accident. He endeavored to establish chiefly that the disability was due to coronary thrombosis brought on by the fall. He called a heart specialist who testified that the accident was the competent, producing cause of coronary thrombosis, but qualified the statement by testifying that the presence of that condition implied pre-existing disease in the coronary arteries. The physician who took the electrocardiograms testified to finding the condition and that it caused plaintiff to discontinue his work indefinitely. The said witness also gave the opinion that the fall caused coronary thrombosis but also said "that in order to have coronary thrombosis of the coronary artery there has got to be a coronary sclerotic condition of the coronary artery and that such a condition is a disease and that if the plaintiff sustained a coronary thrombosis in February, 1940, at that time those coronary arteries were sclerosed." A third expert gave similar testimony for the plaintiff.

The trial resulted in a judgment in favor of the plaintiff, and the insurance company appealed, contending that the evidence showed that the requirements for recovery under the accident policy were nonexistent. The Appellate Division ruled that the judgment of the Trial Court should be reversed, and the complaint dismissed. In its opinion that Court said in part:

"The burden was upon the plaintiff to establish that his disability resulted from the accident exclusively and independently of all other causes and that it was not caused directly or indirectly, wholly or partly, by disease and that such injuries wholly and continuously disabled the plaintiff from the date of the accident and prevented him from performing any and every duty pertaining to his occupation.

"From the plaintiff's own testimony it

[Continued from page 1012]

must be found that the injuries suffered by the plaintiff on the 9th of February, 1940, did not wholly and continuously disable him from the date of the accident and prevent him from performing any and every duty pertaining to his occupation.

"The medical testimony is to the effect that coronary thrombosis could not occur without a previously existing disease of arteriosclerosis in the coronary arteries and that the fall was an aggravation of such existing diseased condition which produced the coronary thrombosis.

"Provisions such as those contained in this policy have been construed to mean exactly what they say, which is that unless the insured is totally disabled from the date of the accident there can be no recovery.

"The plaintiff was not totally disabled between February 9, 1940, and April 1, 1940. . . . He engaged in some of the duties of his profession during that period of time. A clause of the policy provides for indemnity for disability and it requires that the disability, independently of all other causes, shall wholly and continuously disable the insured from the date of the accident from performing any duties pertaining to his occupation. This language excludes indemnity suffered in a second period following one in which there has been no complete disability."

It should be noted that this cause was decided by the Appellate Division. It is possible that our highest Court, the Court of Appeals, may yet have occasion to finally pass upon this case.

Inquiries

YOUR Counsel recently received the following inquiry:

"Dear Sir:

Have I a legal right without violating the privileged communication between patient and physician to state for the defense that I treated the plaintiff years before the cause of action and that I saw her following the action? The plaintiff had an old chronic middle ear disease for which I saw her in 1936. In 1939 I was requested by her attending physician to examine her ear, with a history of having been struck on the head by a falling sign which was followed by noises in her head and vertigo.

She claimed to have had bleeding from the ear at that time.

What are my legal and ethical rights?

Very truly yours,"

Your Counsel's reply was as follows:

"Dear Doctor:

In your letter you inquire as to your legal rights to reveal information obtained by you in connection with the treatment of a patient in 1936, who was later examined by you in connection with the care of injuries claimed to have been sustained in an accident.

"The Statute with respect to confidential communications is found in Section 352 of the Civil Practice Act, which provides so far as material:

"Physicians and nurses not to disclose professional information. A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity."

"Under the prohibition contained in said statute, a physician may not reveal information acquired in attending a patient, unless by express consent of the patient, or unless there may be spelled out an implied waiver on the part of the patient. The Court, in the situation referred to by you, might very well hold that by bringing an action for damages for physical injuries, including injuries to the ear, the patient has waived the right to compel silence with respect to her condition in 1936, as well as in 1939. However, I do not feel that you should place yourself in the position of being the judge as to whether it is proper for you to give the testimony in question.

"I would suggest that if you are called to testify in the case by the defendant, that, when questioned as to treatment, you ask the Court for a ruling as to whether you are entitled to properly reveal your entire knowledge of the case. If the Court rules that you may so testify, the said ruling would serve to protect you from any claim that you had violated your confidential relation with the patient.

Very truly yours,"

OUTLOOK FOR MUMPS CONTROL IMPROVED

An outbreak of mumps in a military establishment may lead to serious consequences in the way of days lost through hospitalization, Conrad Wesselhoeft, M.D., late Captain, Medical Corps, United States Army, Boston, and Charles F. Walcott, M.D., Major, Medical Corps Reserve, United States Army, Cambridge, Mass., declare in the April issue of *War Medicine*, published by

the American Medical Association in cooperation with the Division of Medical Sciences of the National Research Council. Present-day basic knowledge of the nature of this disease and an understanding of how some of its manifestations can be alleviated and its spread prevented should enable one to cope with it more successfully than in the past, the two men say.

"TO PARENTS IN WARTIME"

The care of children in wartime is now gaining more attention as a result of a flood of inquiries from parents received by the United States Children's Bureau. Mostly, these inquiries were about handling the war emergency with respect to the younger members of the American families.

In answer, the Bureau has issued its pamphlet entitled "To Parents in Wartime." The information and advice given in the publication has been prepared by a group of distinguished specialists, and it may be found useful by physicians for distribution to parents of their child patients.

The principle suggestions are "prepare yourself for whatever may come" and "help your children to continue living their everyday lives."

Copies may be obtained from the Superintendent of Documents, Washington, D. C., at five cents each.

Does blood run uphill? A suggestion on technic for brushing the hair casually states "Hang your head down to get the blood into it." No reason is given for letting the blood run into the head—but it is a strong intimation that such an act must be beneficial. Not so many years ago children were warned against hanging with their heads down, yet today getting the head down below the level of the rest of the body serves as first-aid treatment in several instances. Come to think of it—we seldom get into such an unorthodox position as we mature. We sit and stand about sixteen hours a day with heads up and then sleep the balance of the day with head raised on a pillow. Can this be the reason why our faces and heads age quicker than other parts of the body? Why hair thins and falls out, skin wrinkles and eyesight dims? Maybe standing on the head once or twice a day wouldn't be such a bad prescription.

Armies still travel on their stomachs. We see and hear a great deal about food as an essential item in building and maintaining strong offensive armies. The American soldier (at least from our point of view) is probably the best fed in the world. The daily ration for our fighting men, costing about forty-two cents, is considered a triumph of nutritional science. While 5,000 calories are considered the daily requisite for a laborer, our soldier is fed 500 more, which probably accounts for an average gain of weight of from eight to sixteen pounds within a year of service.

Defeat of the Axis is not expected to materialize through starvation. The German soldier may not be receiving as palatable a diet as his American adversary but nutritionally it may be equally as good. He is fed largely a mixture called "bratling powder," composed of soybean, grain, milk, spices, herbs, vitamins, and minerals. Another ration is made up of powdered tomatoes, cheese, apples, and powdered jam—also candies containing dextrose, whey, and "Vitamin C." When there is a shortage of meat, germinating soybeans and rye are used as a substitute.

"Biting equipment" modified. Requirements for service in our armed forces formally stipulated that no man would be accepted unless he had at least 12 teeth—six masticating and six incisor teeth. A new ruling requires only that an applicant or selectee be able to eat and digest Army ration. In other words—now each man is his own Guinea Pig.

DIABETIC SUGAR TEST

Patients are Easily Taught this Simple Spot Test

No test tubes . . . no boiling apparatus . . . no measuring. Three good reasons why your patients will welcome Galatest . . . the convenient "spot test" for the detection of urine sugar. Obtainable in a handy, compact kit, Galatest permits diabetics to follow daily routine sugar tests regularly—wherever they may be.

Galatest is a dry bismuth reagent. One drop of urine on small amount of powder gives an immediate reaction . . . combines maximum selectivity with dependable accuracy.

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Cattaraugus. Twenty-six members attended a luncheon at Gowanda. Dr. Tomlinson took them through the State Institution. The auxiliary members and their husbands held a dinner at the country club at Olean. After the dinner, Dr. Peale of New York gave a lecture.

Cayuga. Dr. W. W. Bauer visited the auxiliary on April 14. He stressed "the part that women play in public health particularly in time of total war." Other outstanding statements made by Dr. Bauer were: "By keeping as well as possible and following a balanced schedule, we can all help to win the war. . . . For total war, we require a very high standard of physical and emotional soundness. . . . It is encouraging from the standpoint of public health to know that 50 per cent of our young men are deemed physically fit to meet the rigorous requirements of total war."

The annual meeting was held at the home of Mrs. Louis D. Burlington in Aurora. Dr. C. Weber of Wells College gave a talk on "Child Psychology." Mrs. Carleton Bullard presided, and after conducting the routine business turned over the gavel to the new president, Mrs. A. B. Chidester.

Officers elected were: first vice-president, Mrs. Everet H. Wood; second vice-president, Mrs. F. E. Barnes; recording secretary, Mrs. E. S. Platt; corresponding secretary, Mrs. A. Cimildora; treasurer, Mrs. H. M. Jones. Mrs. Everet H. Wood and Mrs. A. B. Chidester were elected delegates to the State Convention. Gifts were presented to Mrs. G. B. Adams, retiring president of the State Auxiliary and to Mrs. Bullard, retiring president of Cayuga County auxiliary.

Erie. A luncheon was given in conjunction with the Medical Society at the Hotel Statler. Mrs. Arthur F. Glaeser, president of the auxiliary, appointed the following committees: Mrs. Albert A. Gartner, chairman of organization, assisted by Mrs. James C. Sullivan, cochairman, and Mmes. Stuart L. Vaughan, Lewis F. McLean, and Ralph M. DeGraff; Mrs. William T. Clark, chairman of the ticket committee, assisted by Mrs. William A. Barr, cochairman, and Mmes. Harold F. Brown, Roland B. Carr, Frederick G. Stoesser, Joseph D. Godfrey, William M. Howard, and Edward S. Buffum; Mrs. Walter S. Goodale, head of the reservation committee, assisted by Mrs. Stephen G. DiPasquale, cochairman, and Mmes. Clarence J. Durshordew, Edward A. Sharp, Harold B. Johnson, John T. Donovon, Carlton E. Wertz, and Walter L. Machemer; chairman of the luncheon committee, Mrs. John B. Mulholland, with Mrs. Donald G. O'Connor, cochairman. Other members of this group are Mesdames Joseph A. Tripi, Arthur D. Hennessy, Hyatt Regester, and Robert J. Striegel.

Madison. Mrs. Lee S. Preston, president of the auxiliary, is also a member of the city defense nutrition committee. Mrs. Preston and Mrs. Otto Pfaff attended the executive board meeting

in Albany. Dr. W. W. Bauer of Chicago visited Madison County. Mrs. Preston arranged for Dr. Bauer's visit. Three addresses were given by Dr. Bauer. The first was delivered at a joint meeting of the Oneidas and Rotary clubs at Hotel Oneida. The topic was "Health Problems Today and Tomorrow." The second was given at a meeting in the high-school auditorium, with all of the high-school students present. The topic was "They Ask Us Questions." The third, "Health for Total War," was given at a general public meeting at the Hotel Oneida, following a dinner of the Madison County Medical Society and the auxiliary.

Montgomery. Mrs. Alfred Madden, state legislative chairman, was guest speaker at a meeting held at the Elks Club. Mrs. Edward A. Bogdan has been elected president for the coming year. The other officers elected were: Mrs. L. M. McGuigan, vice-president; Mrs. E. B. Kelly, secretary; Mrs. Raymond Wytrwal, corresponding secretary; Mrs. A. A. Casano, assistant corresponding secretary; Mrs. A. J. Townley, treasurer. Following the meeting a steak dinner was served. Mrs. S. L. Homrighouse, retiring president, was presented with a gift as a token of appreciation for her splendid work. The auxiliary members are urged to cooperate with the Amsterdam City Hospital and St. Mary's Hospital on Hospital Day.

Niagara. A most interesting first-hand account of air raids and duties of air raid wardens in England was given to members of the woman's auxiliary, when Mrs. Alexander Reid, of Kenmore, a former air raid warden in Liverpool, England, spoke after their luncheon meeting in the Delaware Hotel, Tonawanda. As a county organization, the auxiliary is doing all it can to aid County institutions. Samples of codliver oil, prepared cereals, and baby food have been turned over to the Wyndham Lawn Home for Children. Proceeds of \$110 from a book review made possible a series of twelve lessons in oral expression. A definite sum of money has been designated to buy magazine subscriptions for the inmates of the infirmary of the Old Folks Home at Lockport. Mrs. George B. Adams, State Auxiliary president, visited Niagara County. Mrs. Adams gave a very inspiring talk, stressing the idea that even in these busy times women should never be too busy to take part in any health project, as the health of the nation is just as important in wartime as in times of peace.

Rensselaer. At a recent meeting Dr. Frederick L. Patry, psychiatrist, of Albany, addressed the society. The members are registering for a first aid course. Rensselaer County is preparing for a possible food shortage. Miss Jessie Cole, senior nutritionist of the State Health Department, spoke on "Wartime Menu Planning." Miss Cole stated that there are 200 edible weeds in New York State, which could be prepared in appetizing ways.

"THUMB SUCKING"

Some light on child behavior, or at least on the parents' diagnosis of an offspring's queer antics, has been uncovered in a report of some 1,500 cases brought to the Children's Psychiatric Service at the Johns Hopkins Hospital.

From the Johns Hopkins study (Dr. Elliott Jaques in the April issue of *The American Journal of Orthopsychiatry*) it is apparent that a belief in "heredity" or "prenatal influence" accounted for tantrums, feeding difficulties or poor progress in school in the viewpoint of most of the parents. In many of the cases current as well as ancient scares, fads, and folklore were reflected.

According to Dr. Jaques' article, "There were parents who insisted on handing out large doses of laxative indiscriminately to their healthy children. Other parents gave patent medicines to their children weekly because they felt the children should get something." The home remedies administered for emotional difficulties are almost incredible.

Among the more common situations, parents worried because baby sucked its thumb. Considering present-day alarms over this particular form of infant behavior, Dr. Jaques remarks, "It is hard to believe that prior to 1870 the habit was regarded as so natural and harmless that it was never even mentioned in professional litera-

ture. In fact, the only evidence that anyone ever noticed it at all is to be found in the masterpieces of medieval painters who depicted little angels with thumbs in their mouths—to give them the appearance of happiness and tranquility."

That blissfully ignorant era ended fifty years ago with the warning of a Hungarian dentist on the danger of finger sucking. Freud's interpretation of the habit and later opinions of orthodontists that thumb sucking may cause a deformed jaw, combined to scare parents into the use of many "remedies" thrown on the market. Cuffs, muffs, and other "instruments of torture" have been popular as well as painting of bitter substances on the infant's fingers and tying the hands to the bedposts.

Remarks Dr. Jaques, "Of seventy-two cases, no less than thirty-four children had been restrained, scolded, beaten, shamed and otherwise punished—and had gone on sucking their thumbs."

In cases of "nervousness" or "St. Vitus" dance as some parents regarded it—sophisticated mothers wanted their children "psychoanalyzed" without knowing the nature of psychoanalysis, while unsophisticated mothers were resigned to "nerves" because "his grandfather was good for nothing."

FALKIRK IN THE RAMAPOS

A sanitarium devoted exclusively to the individual treatment of MENTAL CASES Falkirk has been recommended by the members of the medical profession for half a century.

REVIEWED

Clinical Aspects of the Electrocardiogram Including the Cardiac Arrhythmias. By Harold E. B. Pardee, M.D. Fourth edition. Octavo of 434 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$5.75.

The acid test of merit of a book on electrocardiography is to use it as a reference volume while reading electrocardiograms. This was done with Pardee's new volume, and it has stood the testing process well. Each day, as tracings were being read in the department of electrocardiography, points illustrated by the electrocardiograms were looked up. In every instance information was found on the matters under discussion. The chapter on the normal electrocardiogram was helpful in settling questions arising out of slight deviations from the normal in the child and the adult. Chapter VIII, "Variations of the Electrocardiogram Resulting From Disease and Other Abnormal Influences," was the most frequently consulted and proved to contain a mine of information. In reality it is a treatise on electrocardiographic patterns and their correlation with clinical disease entities. It is especially valuable because the curves obtained with multiple precordial leads are adequately depicted. This book contains up-to-the-minute information on recent advances in knowledge in electrocardiography. It should be valuable to electrocardiographer, teacher, and student.

EDWIN P. MAYNARD, JR.

Functional Pathology. By Leopold Lichtwitz, M.D. Octavo of 567 pages, illustrated. New York, Grune & Stratton, 1941. Cloth, \$8.75.

The short preface of this valuable publication practically outlines the scope of the book. It will undoubtedly rank with the classics of modern medicine. Dealing as it does with the mechanism of symptoms and signs of disease, a subject for which modern medical men thirst, it should be received with applause. Little that is known of functional pathology today is omitted from this volume. Beginning with the general subjects of endocrinology, regulation of heat, metabolism, and body water, the author follows with an excellent chapter on the pathology of intracellular oxidation which every physician should read. The functional pathology and mechanism of the common metabolic disturbances (the thyroid, arthritis, gout, obesity, skeletal and pluriglandular diseases), as well as the mechanism of defense, are then lucidly discussed. Those especially interested in hypertension, hepatic disorders, or blood dyscrasias will find the chapters dealing with these respective subjects full of interesting discussion and information.

The reader early senses the unorthodox opinions of the author in his interpretations of the various pathologic manifestations of some of the known diseases. However, these opinions are all based upon a profound knowledge of physiol-

ogy and an accumulation of thirty years of experience in trying to correlate bedside observations with laboratory findings. The author seems to have made a special effort to keep dogma out of his expositions, despite his wide knowledge of the subjects which he treats. Hence, the relative absence of the customary stereotyped description of diseases which the reader finds in the average comprehensive standard book on any phase of medicine.

The simplicity with which the reader is guided through the complex problems of function in order to comprehend the mechanisms involved in the less well understood diseases, will be found refreshing to the average practitioner, student, and specialist alike. Here is required the ability of the teacher to amplify his simple formulas and to make it applicable for diagnosis as well as treatment.

The text is well illustrated with pictures, plates, tables, charts, and photographs. The bibliography is quite comprehensive.

S. H. POLAYES

The Man Who Lived for Tomorrow. A Biography of William Hallock Park, M.D. By Wade W. Oliver. Octavo of 507 pages. New York, E. P. Dutton & Company, 1941. Cloth, \$3.75.

It is not an everyday experience to close the covers of a book just finished and feel reluctant to put it down and thus break the spell of reverie and reminiscence which enveloped one's mind during its perusal. That will be the experience of the vast majority of the readers of this charming narrative of the life and works of a great man in medicine.

To the delightful story is added a wealth of information on the application of the progressive steps of medicine to the welfare of a great community.

The ability to present the technical aspects of bacteriology and allied subjects in a manner that holds the interest of the lay, as well as the professional, reader is indeed rare; the biographer has done this.

The history of the progress of medicine since the turn of the century is outlined in panoramic form, giving most illuminating accounts of the great epidemics that visited New York. The more important are: epidemic meningitis in 1904-1906; poliomyelitis in 1916—the extent and seriousness of the epidemic is given by the number of cases, 8,928, and the number of deaths, 2,407. Then there was the epidemic of influenza, and the sporadic outbreaks of typhoid fever, etc.

In Chapter XXVI on "The Gospel of Diphtheria Prevention," the biographer epitomizes the fundamental character of his subject in the following statement: "His ever-active mind was not concerned with partial victories won but was ever projecting itself into the tomorrow within

HOW ADVERTISING HAS CHANGED!

Advertising copy for general commodities now sings a strange tune. The general theme seems to be "buy only what you need—take care of what you own!"

Not so long ago the same business establishment would have high-pressured "better buy a dozen at this price—while you can get them!" And it really meant it as it so sincerely asks us today to respect the wishes of our Government in preventing waste.

That's just another "American Way" of building prestige through sacrifice. No one, least of all Hitler & Company, would believe that American business could be so unselfish, and we haven't as yet appreciated this

fact ourselves to any great extent, but we will catch on one of these days.

While it is always smart to use judgment in buying and caring for things, there is greater need for such intelligent action now. But, remember, it isn't always just a question of quantity—more often it is quality that attains the objective now sought.

America's waste in the past resulted from "cheap" products that seldom outlived the purchase price as much as it did from purchasing things that were not needed.

This, we should remember, too.

[Continued from page 1018]

whose folds were hidden the promise of final conquest." And so the story continues for 471 pages, every one of which is of interest and exhibits a high degree of literary merit.

An unusual and commendable feature is the list of references pertaining to each chapter, and all this followed by a complete index.

The book ends with a letter written by the late Dr. Hans Zinsser to Dr. Park on the occasion of the official dedication of the William Hallock Park Laboratory. It is a fitting conclusion, for one closes the book with a feeling akin to what one felt at the end of Zinsser's *As I Remember Him*.

S. R. BLATTEIS

Operative Surgery Including Anesthesia, Pre- and Postoperative Treatment, Principles of Surgical Technic, Blood Transfusion, and Abdominal Surgery. Edited by Frederic W. Bancroft, M.D. Quarto of 1,102 pages, illustrated. New York, D. Appleton-Century Company, 1941. Cloth, \$10.

The purpose of this work is to present the surgical treatment of abdominal diseases. Symptomatology and diagnosis are included only when the differential diagnosis has a direct bearing upon the type of operation to be performed. For instance, a complete review of the etiology and differential diagnosis of the splenomegalies quite properly precedes the technic of splenectomy.

Thirty-four authors have written upon thirty-four subjects. Each subject is discussed by a man who is an outstanding authority upon it. Only the accepted operations or those that have proved to be of greatest value in the hands of the man describing them have been presented. All antiquated technics have been omitted. There are various important subjects discussed in this volume other than technic of operations—namely, a section on "Anesthesia," made up of six chapters, each written by an outstanding anesthetist. Another section deals with "Blood Transfusion," and "The Use of Blood Substitutes." About 30 pages are devoted to "Pre-operative and Postoperative Therapy," including a discussion "The Evaluation of the Patient," "Fluid and Electrolyte Disturbances," "Acid Alkalosis," "Hypoproteinemia," "Hypovitaminosis," "Shock," "Thrombosis," and "Embolism."

The reviewer was especially attracted by the section on "The Fundamental Principles of Surgical Technic." Each section is prefaced by sufficient anatomy, historical data, or surgical philosophy to put the recommended technic on a rational basis. The authors have spent a great deal of time in preparing and presenting the subjects assigned to them. Each section is really a complete treatise upon the subject rather than simply a recitation of procedure.

The book is sincerely recommended to everyone who is in any way interested in abdominal surgery.

MERRILL N. FOOTE

Essentials of Occupational Diseases. By Jewett V. Reed, M.D., and A. K. Harcourt, M.D. Octavo of 225 pages. Springfield, Charles C. Thomas, 1941. Cloth, \$4.50.

This book, which deals with the essentials of

occupational diseases, is divided into seven chapters: 1. Chemical Poisons; 2. Physical Agents; 3. Skin Lesions of Occupational Origin; 4. Occupational Diseases of the Lungs; 5. Malignant Disease Associated with Occupation; 6. Occupational Diseases Due to Infections; 7. Functional Disturbances Associated with Occupation.

The chapter on chemical poisons occupies approximately one-half of the book. In their discussion of each substance listed as a chemical poison the authors mention briefly the occurrence in industry, the symptoms, and the treatment.

There is an adequate bibliography.

IRVING GRAY

Surgical Diseases of the Spinal Cord, Membranes, and Nerve Roots. Symptoms, Diagnosis, and Treatment. By Charles A. Elsberg, M.D. Quarto of 598 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$14.

The present volume, although containing much of the material already published by the author in *Diseases of the Spinal Cord* (1916) and *Tumors of the Spinal Cord* (1925), is, however, more than a revised edition of his previous books. It contains the results of the considerable additional experience of the author with spinal cord diseases since his last volume on the subject, as well as two very erudite chapters on the roentgen-ray diagnosis and the pathologic anatomy of these lesions by Drs. Cornelius G. Dyke and Abner Wolf, respectively. One may thus turn to this 600-page tome for the latest as well as most authoritative views on the various aspects of the subject. The printing and the halftones are also excellent.

LEO M. DAVIDOFF

The Foot and Ankle: Their Injuries, Diseases, Deformities and Disabilities with Special Application to Military Practice. By Philip Lewin, M.D. Second edition. Octavo of 665 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$9.00.

The first edition of Dr. Lewin's book appeared in 1940. The fact that a second edition appears so soon attests to the reception of this work, and the place it has attained in medical literature.

Dr. Lewin states that world war conditions have led him to accentuate military aspects of the foot. Considerable space in this edition is devoted to injuries and wounds of the foot and their treatment as suffered in actual combat.

The second edition gives us a text fully up to the high character of the first edition. It should prove useful in military surgery.

J. C. RUSHMORE

Diseases of Women. By Harry S. Crossen, M.D., and Robert J. Crossen, M.D. Ninth edition. Quarto of 948 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$12.50.

This new ninth edition is on the same high plane as previous editions of this well-known book. As time goes on, the diagnosis and treatment of gynecologic disorders advance with the increased knowledge of their physiology and pathology. In this new book the authors have

Editorial

Emergency Medical Service

The long period of organizational work of the Medical Division of the Office of Civilian Defense has not received the full recognition and commendation it merits. Charged with the grave responsibility of the preparation of plans for emergency medical service and with the maintenance of liaison with other federal agencies concerned with public health and medical care, it has toiled unremittingly and with the benefit of the best skill and available advice to produce an organization that could be adapted to the use and necessities of every region of the United States.

Speaking before the 136th Annual Meeting of the Medical Society of the State of New York, H. van Zile Hyde, M.D., Senior Surgeon, U.S.P.H.S. (R), Medical Officer, Second Civilian Defense Region, said of the responsibilities of every physician in the state that no matter what his peacetime specialty may be, he is a doctor . . . able to do well those things which the public expects him to do well. There is placed upon physicians the necessity of correlating their activities, as physicians responsible for the care of casualties, with all other emergency services with which they must function. It means that they, as an essential part of the Citizens' Defense Corps, must, during action, place themselves under the orders of the local director of Civilian Defense, just as their colleagues in the Armed Forces must subject themselves to responsible au-

thority. This they can do freely because the local medical profession in each community has borne the responsibility for the organization of the Emergency Medical Service, and a representative of the local profession will guide and assist the director in conducting field operations during action.

Effective protection of the civilian population during such periods requires the full participation of every physician in the area under attack, as well as that of large numbers of physicians in related areas. The present situation, in which we do not know whether, where, or when such attacks may occur in this country, challenges the entire profession to prepare itself for any conceivable eventuality, Dr. Hyde said.

It is heartening to learn from the New York State Health Preparedness Commission, continued Dr. Hyde, that there are now 2,952 physicians, 4,392 trained nurses, and 3,415 auxiliary hospital-trained workers, or a total of 10,759 qualified persons, enrolled in the field casualty service in this state, and that there are 1,080 casualty stations now designated.

The commission reports also that this service is equipped with 1,069 kits of surgical instruments and supplies for field use, 8,332 stretchers, and—excluding New York City, for which all figures are not yet available—5,827 cots, 10,408 blankets, 792 ambulances, and 2,976 other vehicles. We can say, then, that in New

[Continued from page 1020]

presented these advances in a practical manner so that they may be used effectively and with understanding of the principles on which they rest.

Since the last edition was published in 1935, much has been learned about hormones and vitamins with their chemical and physical and vital reactions. This more or less recent knowledge has been clearly set forth in a chapter on the subject, and it is presented to the reader in a form that can be easily used in the treatment of gynecologic disorders.

Much of the text has been rearranged and revised. New additions have been made and many new illustrations have been added. In this edition of an old and standard gynecologic textbook, the authors have given us a book in which the latest thought is set forth in regard to etiology, physiology, pathology, and treatment of gynecologic disease.

This new edition excels those of previous years, and it is a high standard textbook for student and practitioner.

WM. SIDNEY SMITH

William Henry Welch and the Heroic Age of American Medicine. By Simon Flexner and James T. Flexner. Octavo of 539 pages. New York, The Viking Press, 1941. Cloth, \$3.75.

The present volume is one that will be eagerly read by most doctors since it presents the story of one of the most important figures in the history of American medicine, William H. Welch. The career of Welch is also the story of the first pathology laboratory, the beginning of the Johns Hopkins Hospital, and the establishment of the first Institute of the History of Medicine at Johns Hopkins University School of Medicine. On the whole the present volume is a satisfactory biography and is recommended to the medical reader.

GEORGE ROSEN

The Treatment of Burns. By A. B. Wallace, M.B. (Oxford War Manuals.) 16mo of 113 pages, illustrated. New York, Oxford University Press, 1941. Cloth, \$1.50.

This is the second of a proposed Oxford War Manuals of 1941. The first dealt with the *Early Treatment of Wounds*. A third will treat of *Wartime Psychiatry*. They appear in convenient pocket size, with a stiff cover and an adequate index.

In this book an attempt has been made to formulate an easily adaptable method to treat the various types of burns found in wartime in the civilian and military population. Shock and the toxemias of burns are fully considered, with the indications for appropriate treatment and the resulting improvement in mortality and morbidity. The limitations of the so-called "tanning treatment" are explained as are the methods of preventing the deformities that may follow the "major" burns. Reference to the use of certain products familiar to the English, such as eusol and albidic paste, may be a little confusing to the American doctor, but the context or the index offer a ready explanation. If other volumes are equally descriptive and instructive, the set should be made generally available.

JOSEPH RAPHAEL

Pre-eclamptic and Eclamptic Toxemia of Pregnancy. By Lewis Dexter, M.D., and Soma Weiss, M.D. Octavo of 415 pages, illustrated. Boston, Little, Brown & Company, 1941. Cloth, \$5.00.

This monograph discusses in detail the perplexing subject of toxemia of pregnancy. Strangely enough, it comes from the Department of Medicine at Harvard and not from the Department of Obstetrics. Soma Weiss, reviewing his experience as a medical consultant to the Obstetrical Service of the Boston City Hospital, has made a valuable contribution from the "Thorndike."

The authors believe that the evidence at present points to the placenta as the intra-uterine factor responsible. The mechanism is not known in detail, but a chemical (hormonal) mechanism is suspected.

All the possibilities of treatment are discussed—a few in detail. Here the authors are not on such firm ground, and one need not believe all that has been set down; yet this is a book of the utmost importance and quite the best book on this subject which has yet been written. The text is extraordinarily clear and simple, and obstetricians will admit that this thoughtful study by physicians interested in cardiovascular and renal disease is a distinct contribution. No one should fail to read it.

CHARLES A. GORDON

School Health Services. A Study of the Programs Developed by the Health Department in Six Tennessee Counties. By W. Frank Walker, Dr. P.H., and Carolina R. Randolph. Octavo of 172 pages. New York, The Commonwealth Fund, 1941. Cloth, \$1.50.

This book is devoted to a study of school health services analyzed from the point of view of administrative and technical practice and of the results obtained. The material used as a basis for the investigation was the school health department records of some 58,000 children in six representative counties of the state of Tennessee during the years 1930 to 1936. The uniformity in both procedure and recording used by this state in its school health work provided a suitable opportunity for this type of analysis.

The purpose underlying the study was to determine the effectiveness of the school health services so that suggestions for modification and improvement might be formulated. To this end the authors have subjected the large statistical data assembled to a remarkably well-directed analysis. The "longitudinal and cross-section views of child health" provide needed enlightenment on several aspects of a much disputed subject. On the findings the authors present, their deductions seem logical and should have a definite bearing on future planning in the field of school health service. Important emphasis is placed on the development of children free from defects at the time of their school entry by systematic attention to the earlier age groups rather than on the detection of these defects during the years of school life.

By this important study the Commonwealth Fund has again contributed to the furtherance of fundamentals for the health program of the future.

JOSEPH C. REGAN

Terry M. Townsend, M.D.

Dr. Terry Monroe Townsend died May 16, 1942, after a short illness of pneumonia, in the West Side Hospital and Dispensary in New York City of which he was a former president.

Active until shortly before his decease in his sixty-sixth year, he suddenly collapsed on May 14 after attending a meeting of the Committee on Grievances of the New York State Department of Education. Born November 2, 1876, at Jeffersonville, Indiana, of Elam Barsley Townsend and Eliza Rebecca Townsend (nee Terry) he was graduated from the University of Louisville, 1894, and took his medical degree in March, 1897. He practiced in Jeffersonville from 1897 to 1898. He then became a hospital steward in the Spanish-American War, serving until the end of that year. He moved to New York City in 1899, where he practiced urology until the time of his death.

He was a founder of the American Urological Association and was its treasurer for three years. Later, in 1911, he became president of the New York Urological Society. In 1930, he was

president of the New York Medico-Surgical Society, and in 1933 was elected president of the Medical Society of the County of New York.

He was president of the First District Branch of the Medical Society of the State of New York in 1936; trustee of the New York Physicians' Mutual Aid Association, 1927-1937; trustee of the Medical Society of the County of New York, 1934-1938; and became president of the Medical Society of the State of New York in 1939. His life was one of distinguished service to the medical profession.

A fellow of the American College of Surgeons and diplomate of the American Board of Urology, he was also a lover of the outdoors, devoting what time he could to hunting, fishing, and boating. His demise will be regretted by all who knew him in whatever capacity. Good friend and physician, a good fighter for the advancement of the interests of the medical profession, he has earned his rest.

*Home is the sailor, home from the sea,
And the hunter home from the hill.*

More Sweeping Changes

What is there about the practice of medicine that attracts the omniscience of the journalistic field marshals, the hair-trigger fire of the editorial emancipators, the fury for federalization of the reportorial pencil pushers? There must be something.

It appears that physicians, who only work at the practice of medicine, are apparently too close to it, in the opinion of Journalists, to know much about it. The same lack of perspective, the Journalists seem to feel, influences the county, state, and national medical societies. These societies are largely made up of

practicing physicians, which seems to be their chief fault.

On September 8, 1941, the New York Times prescribed expertly for American medicine. . . .¹ It called for "a sweeping change in the pattern of medical practice," along with a number of other proposals in a type of Rx which is known to the trade as a "shotgun prescription." Now, on April 22, 1941, P.M., an enterprising five-cent local paper, carried an article by Albert Deutsch, captioned "Medical Care," with the subhead "Sweeping Changes Required to Meet Wartime Needs." Apparently, many of our local editorial writers and feature scribes have been conditioned at some

¹ See New York State J. Med. 41: No. 20: 2007 (Oct. 15), 1941.

York State there is now an effective field casualty service ready and equipped to go into operation. There remains only the need for perfecting it through repeated drills and exercises.

The War Emergency Act, effective in

this state since the first of May, affords much needed assistance in forwarding the work of those who have toiled day and night to perfect the organization and effective training of the civilian protection service.

Now for Action

Possibly the most significant single action taken by the House of Delegates at the 136th Annual Meeting of the Medical Society of the State of New York was its unequivocal sponsorship of three organizations providing nonprofit medical expense indemnity insurance in this state.

By an overwhelming vote it was resolved "that the Medical Society of the State of New York now officially approve, sponsor, and support in every manner possible the three corporations which have conformed to the principles prescribed by organized medicine for the protection of the interests of both the public and the profession in the organization and operation of medical insurance, namely, The Western New York Medical Plan, Inc., of Buffalo; the Medical and Surgical Care, Inc., of Utica; and the Medical Expense Fund of New York, Inc., of Brooklyn . . . and that notice of this action of the House of Delegates be given to all county medical societies of the State of New York, and that each one be urged to cooperate in every practical manner toward the accomplishment of the successful operation of voluntary nonprofit cash indemnity insurance by these organizations, in order that a system of medical insurance under administrative control of the medical profession shall be developed and maintained."

Speaking at the Conference on Medical Service Plans in Chicago, on February 14, Mr. J. D. Laux, of the Michigan Medi-

cal Service, brought out the fact that there were in the United States thirty-three voluntary, nonprofit medical service plans operating in nine states, with a total enrollment in excess of 750,000 subscribers, and that in thirteen other states programs were well organized for the inauguration of medical service plans. This is surely a good beginning based on sound planning, careful financing, and the necessarily slow collection of sufficient actuarial data which, for medical expense prepayment insurance, did not exist until recently. Cumulative experience, however, now seems to justify a more rapid expansion of this type of medical service, at least in the State of New York, in the opinion of the representatives of the medical profession.

However, for all that whole-hearted support of the organized profession can mean to the furtherance of this kind of nonprofit medical service, a great deal remains for each individual physician to do. People must be informed that such prepaid medical service by these three voluntary nonprofit corporations is available, that each individual physician is a potential professional member of one of the corporations, and that the medical profession itself stands squarely behind them to assure the continuity and the quality of the medical service to be rendered the subscribers.

SCHIZOPHRENIC BRAIN METABOLISM IN THE COURSE OF INSULIN SHOCK TREATMENT*

With Special Reference to Blood CO_2 and the Tendency to Convulsions

JOSEPH WORTIS, M.D., and WALTER GOLDFARB, M.D., New York City

GLUCOSE is the chief fuel of the brain. In 1932 Gerard and Schachter¹ demonstrated that a fall in blood sugar causes a fall in the glucose uptake of the brain. Damashek and Myerson² later demonstrated that brain metabolism is diminished when the brain is deprived of its main foodstuff during insulin hypoglycemia. This observation was confirmed and elaborated by the studies of Himwich, Bowman, Wortis, and Fazekas³ on patients undergoing insulin shock treatment. The present communication presents the data of a large number of further observations on schizophrenic brain metabolism before and after a course of insulin treatment, as well as during insulin coma, with a discussion of some special questions that have arisen with regard to their significance.

Method

The metabolism of the brain was studied in 45 young male schizophrenic subjects before treatment with insulin,[†] during deep insulin coma (three and one-half to four and one-half hours after the insulin injection), and again after a series of thirty or more shocks. Simultaneous blood samples were taken from the brachial or femoral artery and from the internal jugular vein (Myerson, Halloran, and Hirsch⁴), and analyzed for glucose (Hagedorn and Jensen⁵), and oxygen and carbon dioxide (van Slyke and Neill⁶). The peripheral circulation time was estimated by the sodium cyanide method of Robb and Weiss.⁷ A number of observations were also made on the same patients on days in which no treatment was administered.

Results

The observations on blood oxygen are presented in Fig. 1. There are no significant differences between normal and schizophrenic subjects so far as the oxygen content of the arterial and the internal jugular blood samples

are concerned. It may be seen, however, that during insulin coma there is a marked reduction of the arteriovenous O_2 difference. Although there is a slight fall of the arterial oxygen content during coma, this reduced arteriovenous O_2 difference is principally due to a higher concentration of oxygen in the internal jugular vein during coma. The peripheral circulation time showed no significant change. After a course of thirty or more insulin treatments, the oxygen content of the arterial and internal jugular blood and the arteriovenous O_2 difference were found to be within normal limits.

Observations on the CO_2 content of the blood are presented in Fig. 2. It may be seen that approximately 75 per cent of the CO_2 values in the untreated schizophrenic patients are within normal limits, and the remaining values are much lower than normal. During coma there is a significant increase of the arterial CO_2 content. After a course of thirty or more shocks, the CO_2 content of the arterial and internal jugular blood was found to be within normal limits.

The course of the arterial CO_2 content during insulin hypoglycemia, both with and without convulsive seizures, is presented in Fig. 3. These curves are based on determinations made on several patients. It may be seen that the CO_2 content rises significantly shortly after the insulin injection, and in the absence of a seizure remains at a high level until the coma is terminated with glucose. In the cases that develop convulsive seizures, the CO_2 content was found to rise markedly immediately preceding the seizure. As the seizure subsides there is a period of hyperpnea which results in a marked fall of the CO_2 content.

A summary of the data is presented in Table 1. In 11 cases in which glucose determinations were made after a course of treatment with insulin, there was a diminution of glucose uptake (from 11 to 6 mg. per hundred cc.) but statistical analysis reveals that the change is of questionable significance.

Discussion

Estimation of Brain Metabolism from Arteriovenous Differences.—In order to estimate

time in their lives by employment, perhaps as broom salesmen, judging from the repetitious pattern of their proposals, or have been subjects for "occupational therapy" as broommakers. This occupation passes the time, we are informed, as well as any other—pleasantly, and it does not require an inordinately high I.Q. However, we digress.

"The top kicks of organized medicine [physicians to you]¹ are waging a desperate fight to retain the medical status quo, war or no war," says P.M. Why not, we ask? We have been through wars before, field marshals; they come and they go; when you are older and less excitable, you will know that, too. But don't forget, field marshals, that our usual responsibilities continue unabated, wars or no wars. True, wars accentuate them, increase them, but they do not alter them. We have only our experience to guide us of course, but, such as it is, it will have to serve. The medical status quo is very simple; it consists in maintaining the highest quality of medical service to the public of which the profession is capable. A little more difficult under war conditions, naturally, but the same old status quo, field marshals. Remember that when you write: "The answer is obvious . . . Medical care as presently organized is not geared to emergency needs." Do you really believe, field marshals of the press, that the President's proposal "that sickness and disability benefits for workers be added to the federal social security system" is the obvious answer? If physicians thought

so, why should they oppose it, field marshals? Do you think that federal supervision and subsidy of the press would aid in gearing journalism as presently organized to meet emergency needs? We should not presume to advocate it, even if you thought so, because our business is the practice of medicine, the practical business of providing the best medical service of which the profession is capable. It takes all of our time.

"Tens of thousands of doctors," says P.M., "are leaving civil practice to enter military service. The call has gone out for 50,000 more trained nurses for our armed forces." That is true. The loss to civilian practice of so many physicians and nurses is a serious matter. There never are a great number of either in the general population who are trained and able to produce the kind of medical service on which the profession, obstinately, if you will, insists.

In the opinion of organized medicine, field marshals of the press, these physicians and nurses are the only qualified personnel able to provide safe, competent medical service to the public. With all due respect to other opinion, is it reasonable or not that these physicians should be permitted to carry on in the way which they have found to work practically and safely in the public interest? Or shall the admitted difficulties of the proper performance of their work under war conditions be increased by submitting the sound and tested structure of their organization to the vagaries of untried, theoretically attractive but unproved, political management? You answer that one, field marshals. To us, it seems obvious.

¹ Our Note. The war is definitely altering the journalistic attitude toward everything.—Ed.

Registration of Diathermy Apparatus Ordered by Federal Communications Commission

All possessors of apparatus designed, constructed, or used for generating radio frequency energy for therapeutic purposes, described generally as diathermy apparatus, must register each such device with the Federal Communications Commission in Washington, D. C., by June 8, under Order No. 96, promulgated by the commission on May 18.—See *J.A.M.A.* 119: 354 (May 23) 1942.

FIG. 2. Carbon dioxide content of the blood in normal and in schizophrenic subjects.

vertebral veins, and since the diameter of these veins remains nearly constant, changes of the linear rate of internal jugular blood flow can be regarded as a reasonably safe measure of changes in volume and rate of flow through the brain, regardless of the many diverse influences to which this rate of flow may be exposed.

Thus, in actual practice, internal jugular blood flow and arteriovenous differences should suffice to give a fairly clear picture of the oxygen uptake of the brain. The slower or unchanged peripheral circulation rate, and the demonstrably unchanged or slower jugular blood flow, together with the markedly diminished oxygen uptake, support the conclusion that brain metabolism is markedly diminished in insulin coma. Diminution of the arteriovenous differences to less than half the normal value could be explained by a change of blood flow alone only if the rate of flow were doubled. There is no reason to assume so extraordinary an increase in brain blood flow during insulin coma, and all available evidence is against it.

The Diminished Brain Metabolism of Insulin Coma.—We have seldom found an arteriovenous oxygen difference exceeding 5 volumes per hundred cc. during insulin coma, and a value below 5 volumes per hundred cc. was

seldom observed after arousal. This value of 5 volumes per hundred cc. would thus seem to mark a critical level between coma and arousal.

The correlation between arterial blood sugar and the brain uptake of oxygen is made clear in Fig. 4. It should be emphasized, however, that this correlation applies only to the groups of cases studied in this and one previous report.¹² In certain other conditions, such as irreversible coma, the oxygen uptake of the brain remains low, in spite of abnormally high blood sugar levels.¹³ The correlation between oxygen uptake and blood sugar is much closer than that between glucose uptake and blood sugar, presumably because the brain tissue carries reserves of carbohydrate but not of oxygen. For possibly the same reason there is no intimate correlation between the oxygen and the glucose uptake of the brain, though the average glucose uptake in insulin coma amounts to about half the resting value.

Blood CO₂ and the Tendency to Seizures.—It will be noted that the uncompensated rise in arterial CO₂ occurs very early in the course of hypoglycemia, generally at least two hours before the development of coma, and long before the flushing, perspiration, twitchings, and dystonic movements characteristic of deep hypoglycemic shock appear. This apparent depression of the function of the medullary

the uptake or release by the brain of any blood constituent, it is necessary to determine not only the arterial and venous concentrations of that constituent, but also the rate of flow of a given volume of blood through the brain. The oxygen uptake, for example, thus becomes dependent on the three factors of arteriovenous difference, linear rate of flow, and total diameter of the blood vessels entering or leaving the brain, and should be expressed in units of gas volume per unit of time for the brain as a whole. Since the amount of brain tissue involved varies from case to case, this uptake per unit of time must also be correlated to the total weight of the brain before any conclusions regarding the metabolic activity of the brain tissue can be reached. Such accuracy is only possible in perfusion experiments in which rate and volume of flow can be regulated, and where the total weight of the brain can be determined. Under the experimental conditions in which our own observations were made, we would be entitled to conclude that brain metabolism is markedly diminished during insulin coma only if the other variable factors remained reasonably uniform.

Since patients from the same groups were

used as controls, brain weight can be assumed to be a constant. What data are available to indicate changes in the two remaining factors, blood flow and diameter of the afferent or efferent vessels? According to Loman and Myerson,⁸ blood flow through the internal jugular vein is unchanged or slightly diminished during insulin hypoglycemia. Leibel and Hall⁹ in animal experiments found no change in cerebral blood flow during hypoglycemia unless convulsions occurred. In collaboration with Drs. Himwich, Daly, Bowman, and Fazekas,¹⁰ we have made simultaneous observations of blood flow and arteriovenous O_2 difference in patients during insulin hypoglycemia. The arteriovenous O_2 difference invariably fell, while the blood flow showed a tendency to progressive slowing during coma. Since cerebral blood flow is mainly dependent on systemic blood pressure (Forbes and Cobb¹¹), these observations accord with what is known to be the typical effect of insulin shock on blood pressure, which generally shows lower diastolic and higher systolic values during coma.

Since, furthermore, all blood leaving the brain must pass through the internal jugular or

vertebral veins, and since the diameter of these veins remains nearly constant, changes of the linear rate of internal jugular blood flow can be regarded as a reasonably safe measure of changes in volume and rate of flow through the brain, regardless of the many diverse influences to which this rate of flow may be exposed.

Thus, in actual practice, internal jugular blood flow and arteriovenous differences should suffice to give a fairly clear picture of the oxygen uptake of the brain. The slower or unchanged peripheral circulation rate, and the demonstrably unchanged or slower jugular blood flow, together with the markedly diminished oxygen uptake, support the conclusion that brain metabolism is markedly diminished in insulin coma. Diminution of the arteriovenous differences to less than half the normal value could be explained by a change of blood flow alone only if the rate of flow were doubled. There is no reason to assume so extraordinary an increase in brain blood flow during insulin coma, and all available evidence is against it.

The Diminished Brain Metabolism of Insulin Coma.—We have seldom found an arteriovenous oxygen difference exceeding 5 volumes per hundred cc. during insulin coma, and a value below 5 volumes per hundred cc. was

seldom observed after arousal. This value of 5 volumes per hundred cc. would thus seem to mark a critical level between coma and arousal.

The correlation between arterial blood sugar and the brain uptake of oxygen is made clear in Fig. 4. It should be emphasized, however, that this correlation applies only to the groups of cases studied in this and one previous report.¹² In certain other conditions, such as irreversible coma, the oxygen uptake of the brain remains low, in spite of abnormally high blood sugar levels.¹³ The correlation between oxygen uptake and blood sugar is much closer than that between glucose uptake and blood sugar, presumably because the brain tissue carries reserves of carbohydrate but not of oxygen. For possibly the same reason there is no intimate correlation between the oxygen and the glucose uptake of the brain, though the average glucose uptake in insulin coma amounts to about half the resting value.

Blood CO₂ and the Tendency to Seizures.—It will be noted that the uncompensated rise in arterial CO₂ occurs very early in the course of hypoglycemia, generally at least two hours before the development of coma, and long before the flushing, perspiration, twitchings, and dystonic movements characteristic of deep hypoglycemic shock appear. This apparent depression of the function of the medullary

FIG. 3. Arterial carbon dioxide content during (a) a single insulin hypoglycemic coma and (b) hypoglycemic coma complicated by convulsive seizures. (Based on determinations made on several patients.)

respiratory center occurring early in the hypoglycemia does not accord with the widely held belief that the earlier symptoms of hypoglycemia may be attributed merely to cortical depression (Frostig¹⁴). The simultaneous occurrence of cortical and medullary depression suggests instead that the brain reacts as a unit to the hypoglycemia, with new constellations of symptoms appearing at each successive stage of hypoglycemia without reference to any anatomically circumscribed localization.

According to our data, the CO₂ of the blood not only rises during insulin coma but shows a rise after a course of insulin shock treatment as well. But whereas the rise during insulin coma is most marked in the arterial blood and

is associated with a diminished CO₂ exchange, the rise after a course of insulin treatment is more marked in the blood drawn from the internal jugular vein and is associated with a normal total brain metabolism. Inasmuch as the CO₂ content of internal jugular blood probably closely approximates the CO₂ content of the brain tissue, this change is of particular interest and importance. The data of Gibbs, Lennox, and Gibbs,¹⁵ as well as those of other workers, show that the CO₂ content of internal jugular blood of normal individuals fluctuates within fairly narrow limits ranging from 51 to 56 volumes per hundred cc. In comparison with other groups of cases we have studied, the average value of 51.5 per hundred

13 VOLUMES PER CENT OXYGEN UPTAKE

FIG. 4. Correlation of arteriovenous oxygen difference of the brain and arterial blood sugar. The single line represents the mean of observations with the Folin-Wu sugar method, and the double line represents observations with the Hagedorn-Jensen sugar method. This correlation applies to the patients studied in this report, in addition to a hyperglycemic group of chronic alcoholic patients. It does not apply to all clinical states.

cc. found in our schizophrenic subjects is definitely low; it is equaled only in our senile patients, and exceeded only in patients in acute alcoholic intoxication.¹² It is 1.7 per cent below the value found in our normal controls. Moreover, the distribution of the values is unusual, in so far as there is a large proportion of cases with normal values and a smaller but significant proportion with remarkably low values, ranging as low as 40 volumes per hundred cc. This type of distribution closely resembles that found by Gibbs *et al.*¹⁵ in patients suffering with petit mal. It should be emphasized, however, that there were no apparent correlations between the CO_2 values and clinical states, and that patients sometimes showed low and normal values, respectively, on successive days.

The CO_2 content of the blood leaving the brain through the internal jugular vein showed little variation as between the awakened and the comatose state, but the arterial CO_2 rose from the relatively low value of 46 volumes per hundred cc. to the abnormally high value of 54 volumes per hundred cc. during coma. Although the respiratory rate was unchanged during coma, the respirations were shallow and the volume of air exchanged per minute was reduced. The high arterial CO_2 levels prob-

ably resulted from this reduced air exchange in the lungs. The smaller arteriovenous difference of CO_2 is consistent with the lower brain metabolism.

In view of the hypoglycemic patient's tendency to fits and epileptoid twitchings, it is interesting to compare the distribution of CO_2 values in insulin coma with the significant changes observed by Gibbs *et al.* in epileptic subjects. In making this comparison it will be found that the arterial CO_2 of the patient in insulin coma tends to be even higher than that of the epileptic patients subject to grand mal seizures. In two of our subjects where the specimens were taken immediately (ten minutes and one minute, respectively) before the onset of typical and severe hypoglycemic seizures, the arterial CO_2 was unusually high and the oxygen uptake unusually low. The values in these cases were 54.7 volumes per hundred cc. at ten minutes, and 56.8 volumes per hundred cc. at one minute before the seizure. Arterial blood taken at the onset of the clonic phase of a seizure in another patient revealed an abnormally high value of 60 volumes per hundred cc. It would appear that these sharp rises in arterial CO_2 occur only a few minutes before the seizure. Gibbs *et al.* found that the arterial CO_2 of epileptic pa-

* The numbers in parentheses represent the number of observations on which the averages are based.

tients suffering from grand mal seizures rose over a period of several days preceding the seizure. Following the seizure there was a marked fall of the arterial CO_2 content, and a subsequent return to normal levels. The authors concluded that the time relations of the CO_2 curves and the seizures indicated a causal linkage between the rise of the CO_2 and the seizures. In the present study we have found a similar rise of CO_2 preceding the insulin hypoglycemic seizure. In these cases, however, the time interval is a matter of minutes rather than of several days.

The increased CO_2 content of both arterial and internal jugular blood should normally induce a compensatory hyperpnea by stimulation of the medullary respiratory center. The absence of any such adequate compensatory regulation and the diminution of O_2 content of the arterial blood indicate that the respiratory center shares in the general depression of brain function during insulin hypoglycemia and coma. A similar depression of the respiratory center occurs in other forms of narcosis (Seevers *et al.*¹⁶), as well as in normal sleep (Page¹⁷). Cheyne-Stokes breathing is not uncommon during insulin hypoglycemia. The relation of this depressed respiratory function to the development of seizures requires further elucidation.

Oxygen Utilization in the Course of Treatment.—Because of the demonstrable diminution of brain metabolism during insulin hypoglycemia, it was tempting to suspect, in the early days of the treatment, that after a series of insulin shocks there was a compensatory stimulation of brain metabolism. It is important to emphasize that the sustained effect of a long course of treatments may be quite different from the immediate effect of a single shock, and that even the end effect may be different in responsive and unresponsive cases. Loman¹⁸ has demonstrated that there is a slow revival from the depression of brain function immediately after insulin coma, but this would not in itself exclude the possibility that the end

result of treatment might be a stimulation of brain metabolism. However, all the data at present available indicate that the oxygen uptake of the schizophrenic brain is normal to start with, and does not need to be stimulated to normal values. Earlier work by Damashek and Myerson² showed normal values for the arteriovenous oxygen difference in a group of schizophrenic patients, and the present report confirms their findings. We have also found that the oxygen arteriovenous difference remained normal—no more and no less—after a course of thirty or more insulin treatments, so that it appears unlikely that the beneficial effects of insulin shock can be attributed to a merely quantitative stimulation of brain metabolism.

There still remains the possibility that there are significant quantitative changes of an order of magnitude too small for detection by this method. It is pertinent in this connection to report that even in patients with general paresis, where there can be no doubt of the existence of an organic brain lesion, we have not found any significant diminution of the total brain metabolism.

But the most important possibility remaining is that the changes in brain metabolism induced by insulin shock treatment are qualitative rather than quantitative. The regular increase in blood carbon dioxide content during insulin hypoglycemia, especially before a seizure, is an example of a significant qualitative change in brain metabolism. According to our data there is also a rise in the CO_2 content of internal jugular blood from the relatively low value of 51.5 volumes per hundred cc. preceding treatment to the relatively high figure of 55.4 volumes per hundred cc. after a course of treatment. We have also found—as Loman did—that the glucose uptake does not rise to normal values with the oxygen uptake, either after the termination of coma (Wortis and Goldfarb¹⁹), or after a full course of treatment. Since the respiratory quotient remains close to unity, it would seem that the low glu-

cose uptake is probably due to the oxidation of intracellular stores of carbohydrates. But further elucidation of these *qualitative* metabolic changes in the course of insulin shock treatment remains a task for the future.

Summary and Conclusions

The metabolism of the schizophrenic brain was studied before and during insulin hypoglycemic coma as well as before and after a series of treatments. The arteriovenous oxygen difference of the schizophrenic brain did not differ from the normal, and no change in the average arteriovenous oxygen difference was observed in a group of schizophrenic patients after a course of thirty or more shock treatments. During insulin coma the arteriovenous oxygen differences were regularly found to be markedly reduced. The arterial CO_2 content was elevated within one hour after the insulin injection, and returned to normal within half an hour after glucose administration. In cases which developed seizures, the arterial CO_2 was found to rise sharply preceding the onset of convulsions. During or following the postconvulsive period of hyperpnea very low CO_2 values were found. These results indicate that there is a depression of the respiratory center during insulin hypoglycemia which results in a decreased sensitivity to the normal stimulus of blood carbon di-

oxide. In those patients who showed abnormally low blood CO_2 values preceding treatment, the tendency of the treatment was to restore normal values.

PREMARITAL EXAMINATION LAWS

Details of operation of the thirty premarital examination laws now in effect in the United States, summarized in the *J.A.M.A.* for March 7 by George F. Foster, Ph.D., and Howard J. Shaughnessy, Ph.D., Chicago, illustrate, they say, "the difficulties which are in many cases imposed on those who cross state lines in order to marry. These difficulties arise chiefly from the lack of reciprocity in the acceptance of (1) laboratory reports from out-of-state laboratories and (2) examination certificates signed by out-of-state physicians."

Interstate marriages are common in normal times and are now considerably increased as a result of the translocation of many eligible young men in the army camps, they explain. The layman often does not understand that he can best secure authentic information about the procedure in another state from the health department of that state. The data presented by the two men in their article now make it possible for laymen to obtain authentic information from the thousands of physicians who receive the *Journal* as well as from health departments.

P. & S. ALUMNI DINNER

The annual American Medical Association dinner of the Alumni of the College of Physicians and Surgeons, Columbia University, will be held at the Hotel Claridge in Atlantic City, New Jersey, on Wednesday, June 10, 1942, at 7:00 p.m. The local committee in charge will be Dr. Robert B. Durham, '23, chairman, Dr. John S. Irvin, '12, and Dr. Clifford K. Murray, '25.

ALL CLASSIFIED

Visiting nurse: "How many in your family, madam?"

She (snappily): "Five—me, the old man, kid, cow, and cat."

Visiting nurse: "And the condition of your family?"

She: "I'm a Republican, the old man's Democrat, the kid's wet, the cow's dry, and the cat's a Mormon."

—*Medical Record*

TABLE 1.—SUMMARY OF DATA ON BRAIN METABOLISM

Diagnosis	No. Pa- tients	Oxygen			Carbon Dioxide		Arteriovenous Diff.		Circ. Time Sec.
		Vol. per 100 cc.			Vol. per 100 cc.		Mg. per 100 cc.	Circ. Time Sec.

After 30 insulin shocks	15	19.13 (22)	12.13 (15)	6.69 (15)	48.36 (22)	55.41 (15)	5.7 (11)		12.9 (16)

* The numbers in parentheses represent the number of observations on which the averages are based.

tients suffering from grand mal seizures rose over a period of several days preceding the seizure. Following the seizure there was a marked fall of the arterial CO₂ content, and a subsequent return to normal levels. The authors concluded that the time relations of the CO₂ curves and the seizures indicated a causal linkage between the rise of the CO₂ and the seizures. In the present study we have found a similar rise of CO₂ preceding the insulin hypoglycemic seizure. In these cases, however, the time interval is a matter of minutes rather than of several days.

The increased CO₂ content of both arterial and internal jugular blood should normally induce a compensatory hyperpnea by stimulation of the medullary respiratory center. The absence of any such adequate compensatory regulation and the diminution of O₂ content of the arterial blood indicate that the respiratory centers share in the general depression of brain function during insulin hypoglycemia and coma. A similar depression of the respiratory center occurs in other forms of narcosis (SeEVERS *et al.*¹⁶), as well as in normal sleep (Page¹⁷). Cheyne-Stokes breathing is not uncommon during insulin hypoglycemia. The relation of this depressed respiratory function to the development of seizures requires further elucidation.

Oxygen Utilization in the Course of Treatment.—Because of the demonstrable diminution of brain metabolism during insulin hypoglycemia, it was tempting to suspect, in the early days of the treatment, that after a series of insulin shocks there was a compensatory stimulation of brain metabolism. It is important to emphasize that the sustained effect of a long course of treatments may be quite different from the immediate effect of a single shock, and that even the end effect may be different in responsive and unresponsive cases. Loman¹⁸ has demonstrated that there is a slow revival from the depression of brain function immediately after insulin coma, but this would not in itself exclude the possibility that the end

result of treatment might be a stimulation of brain metabolism. However, all the data at present available indicate that the oxygen uptake of the schizophrenic brain is normal to start with, and does not need to be stimulated to normal values. Earlier work by Damashek and Myerson² showed normal values for the arteriovenous oxygen difference in a group of schizophrenic patients, and the present report confirms their findings. We have also found that the oxygen arteriovenous difference remained normal—no more and no less—after a course of thirty or more insulin treatments, so that it appears unlikely that the beneficial effects of insulin shock can be attributed to a merely quantitative stimulation of brain metabolism.

There still remains the possibility that there are significant quantitative changes of an order of magnitude too small for detection by this method. It is pertinent in this connection to report that even in patients with general paresis, where there can be no doubt of the existence of an organic brain lesion, we have not found any significant diminution of the total brain metabolism.

But the most important possibility remaining is that the changes in brain metabolism induced by insulin shock treatment are qualitative rather than quantitative. The regular increase in blood carbon dioxide content during insulin hypoglycemia, especially before a seizure, is an example of a significant qualitative change in brain metabolism. According to our data there is also a rise in the CO₂ content of internal jugular blood from the relatively low value of 51.5 volumes per hundred cc. preceding treatment to the relatively high figure of 55.4 volumes per hundred cc. after a course of treatment. We have also found—as Loman did—that the glucose uptake does not rise to normal values with the oxygen uptake, either after the termination of coma (Wortis and Goldfarb¹⁹), or after a full course of treatment. Since the respiratory quotient remains close to unity, it would seem that the low glu-

day, which is more than substantial for the average patient. The great majority of cases were maintained comfortably on doses ranging from 5 to 10 drops three times a day. The optimal dose for the individual patient was determined by a balance between the level of maximum response and that of avoidance of annoying reactions from the drug. The obese individuals were found to tolerate slightly larger amounts than the thin ones. In warm weather, it was found necessary to reduce the dose to about half the usual amount, because atropine inhibits perspiration and accelerates the heart, thereby adding to the circulatory strain caused by the heat.

The time interval between doses is of signal importance in this treatment, since it is desirable that most of the drug be eliminated before the succeeding dose is taken.^{15*} Hence particular care must be taken to stress this factor with the patient and definite hours set for the medication. A preferred schedule for those taking atropine three times a day is 8 A.M., 3 P.M., and 10 P.M. All patients should be started with treatment three times a day in order to gage their responses and individual needs. In the course of time, however, some patients may be changed to treatment twice a day, particularly if the dryness and blurring of vision lead to discomfort or interfere with work. After the initial trial period has established tolerance and response to the drug, a few patients have found it possible to carry on comfortably with treatment once a day, taken upon retiring.

The medicine is inexpensive, a month's supply costing only about 50 cents, hence atropine solutions should be discarded after a month, since some deterioration occurs. The patient should also be instructed to discard any mixture that he prepares in which by accident he has poured more than the prescribed number of drops. He should be advised to use one-half to a full glass of water for each dose of atropine, and since dryness almost always accompanies the treatment, little objection is met on this score.

Common and Unusual Reactions†

Every patient should be prepared to expect some degree of dryness of the mouth and blurring of vision. For the dryness, various mint

candies, chewing gum, and large amounts of water have been found helpful, and for the cycloplegic blurring some patients wear glasses; others make temporary use of a magnifying glass for close work, but the greater number of cases achieve natural visual adaptation as the tolerance for atropine improves.

There were but two instances of mild bladder inconvenience as a result of the moderate-dosage atropine treatment, hence a former practice of preparing patients, especially males, to anticipate bladder hesitancy and straining has been discontinued.

Nausea and vomiting were found to occur during the early stages of treatment in about one patient in 10, and because these reactions always imply an idiosyncrasy to the drug, and are viewed with some alarm by the patient and family, it became a routine practice to prepare every patient to expect that, in the event of the appearance of such symptoms, the medicine would be discontinued for a day or two, and resumed with smaller doses and a slower rate of increase until better tolerance was established. With these precautions, no difficulties were encountered on this score.

Mention is made in the literature, particularly by Meulen,¹⁰ of the dangers and violent reactions that accompany sudden withdrawal of massive doses of atropine. No such reactions were noted with moderate-dosage atropine, although in a few instances patients complained of a return of stiffness in the limbs, nervousness, and slight weakness upon the sudden discontinuance of treatment, but these symptoms found ready adjustment.

Other reactions and complaints that reach the doctor from time to time in the course of treatment are dryness of the skin, dysphagia due to throat dryness, loss of appetite, flushing of the face, sensation of body warmth, transient giddiness, constipation, etc. (see Table 1). These symptoms are of temporary nature, never serious, and are managed according to

TABLE 1.—TYPES OF REACTION WITH MODERATE-DOSAGE ATROPINE

Common and Unusual Reactions	No. of Cases	Percentage of Cases
Dryness of mouth	104	93

* Roemer¹ also states that Palewka at Tübingen Institute proved that atropine is not accumulated in the body, most of it being eliminated in eight hours.

† To date, since the writing of this paper, there have been no unfavorable reactions under the continued-treatment program.

MODERATE-DOSAGE ATROPINE TREATMENT OF THE PARKINSON SYNDROME

A Review of 112 Treated Cases

LEWIS J. DOSHAY, M.D., New York City, and THEODORE R. FORD, M.D., East Orange, New Jersey

THE atropine treatment of parkinsonism owes its origin to a discovery by Bremer,¹ in 1925, that Parkinson cases have a high tolerance for atropine. Not until several years later was the clinical application of this finding realized, when an elaborate system of therapeutic procedure was evolved at the Hirsau sanatorium, Württemberg, under the direction of Dr. Roemer,² who made a report on the massive-dosage atropine treatment in 1930.* Although the atropine therapy came into existence only ten years ago, a wealth of literature has accumulated on the subject, outstanding in which are the contributions of Kleeman,³ Stemmlinger,⁴ Marinesco and Facon,⁵ Read,⁶ Schachter,⁷ Meesen,⁸ Ehrenberg,⁹ Meulen,¹⁰ Adams and Hays,¹¹ and Hall.¹² The authors, with few exceptions, appraise highly the massive-dosage atropine treatment and its results,¹³ but make frequent reference to dangerous and disturbing reactions that accompany the treatment.

In a previous study by one of the present writers,¹⁴ devoted to ergographic estimations of rigidity, incidental and yet significant notations were made, in a small group of cases treated with massive dosage and moderate dosage, that excess atropine was devoid of special advantages, and that serious reactions accompanied the massive doses, with ensuing death of one patient during the summer. It seemed desirable to evaluate these observations further in a larger group. A moderate-dosage atropine routine was followed with 112 patients for periods ranging from several months to four years. Nineteen of these cases were seen in private practice, and the rest were under study and treatment at the Neurological Institute and the Vanderbilt Clinic. With the exception of 3, the cases were of the post-encephalitic type. The ages ranged from 14 to 56 years, with 75 per cent between the ages

of 25 and 42 years. With the exception of 4 cases, all the patients had had symptoms of parkinsonism for more than three years before moderate-dosage atropine treatment was started, and in 36 per cent of the cases the symptoms had existed for from eight to twenty years. The essential aims of the investigation were to establish whether moderate-dosage atropine treatment can retain the advantages of the massive-dosage program, and whether it can obviate the disturbing reactions of the latter treatment.

Moderate-Dosage Atropine Regimen

Roemer,² in his original program, employed increasing doses of $\frac{1}{4}$ per cent atropine sulfate solution. This was shortly after replaced by the $\frac{1}{2}$ per cent solution, because of the advantage of its requiring fewer drops per dose, and because it simplified the calculation of the amount of the drug per dose. Thus, each drop of the $\frac{1}{2}$ per cent solution is equivalent to $\frac{1}{200}$ grain of atropine, 5 drops to $\frac{1}{40}$ grain, 10 drops to $\frac{1}{20}$ grain, etc. The $\frac{1}{2}$ per cent atropine sulfate solution was regularly employed in this survey.

Every patient was provided with written specific instructions as to the number of drops to start with, the amount and frequency of increase of the dose, and the desired time interval between doses. The poor prospect was started with 1 drop of atropine solution, the average patient with 2 drops, and the robust patient with 3 drops, three times daily. The patients were regularly advised to use only a standardized dropper, measuring one minim to each drop of solution.

The rate of increase varied slightly with the patient, depending upon his tolerance and special idiosyncrasies. Various methods of safe and slow increase in dosage were utilized; a practice frequently employed was to increase by 1 drop three times a day, at intervals of three days, until 6-drop doses were reached, thereafter increasing at greater intervals and with greater caution, until the level of 10 drops three times daily was reached. Ten drops contain $\frac{1}{20}$ grain of atropine, and taken three times a day total about $\frac{1}{7}$ grain for the

From the Department of Neurology, College of Physicians and Surgeons, Columbia University, and the Neurological Institute of New York.

* Roemer is widely credited with initiating the massive-dosage atropine treatment at his sanatorium, despite the fact that a report on the treatment by Kleeman, one of his assistants, antedated Roemer's report by one year.

Fig. 2b. Case 2. Same patient three weeks later, following moderate-dosage atropine therapy. Note freer, livelier, and more youthful expression. Now working.

Illustrative cases in the series of the much-improved group are submitted for inspection as to the worth of the therapy. Occasionally one obtains seemingly remarkable results, such as will be noted in Cases 2, 5, and 10, although these may be but temporary phases.

Case Reports

Case 1.—In this man, aged 40, and married, signs of parkinsonism set in during 1932, with pronounced rigidity of the trunk and extremities, tremor, difficulty in swallowing, and uncontrollable laughing spells. He had received large doses of hyoscyne and injections of an unknown substance, but became progressively disabled, so that he had to be fed, dressed, and assisted in getting about. His body assumed a doubled-over posture. Because of the extreme burden of caring for him, he was compelled to live away from his family for over a year. Atropine treatment was commenced July 10, 1937, and within three weeks he had regained sufficient freedom and power in his limbs and body to take care of his personal needs, to get about with ease, and travel a great distance to the clinic alone. His improved condition made it possible for him to rejoin his family (see Figs. 1a

and 1b).^{*} He has continued to maintain his improvement to the present time on 5 to 8 drops of atropine, three times a day.

Case 2.—A woman, aged 25, single, at the age of seven, in 1919, suffered an acute attack of encephalitis following influenza. At 14, definite Parkinson symptoms appeared, and these increased in severity despite treatment with hyoscyne and tincture of stramonium. Examination in March, 1937, showed marked rigidity of the neck and extremities, tremors, oculogyric crises, a markedly somnolent appearance, with drooping lids, a gaping mouth, and drooling of saliva by day and night (see Fig. 2a). She was placed on moderate-dosage atropine and after three weeks there was a marked improvement in appearance (see Fig. 2b), the drooling and gaping of the mouth were entirely controlled, speech became freer, and the oculogyria was controlled. She regained interest in her personal needs, and began to work in a store, whereas prior to the treatment she had led a vegetative existence. She was maintained on 8 to 10 drops of atropine twice a day and, when re-

^{*} The graphs are copies of originals in a paper by one of the authors.¹⁴ Permission to use the graphs for this paper was granted by the editor of the *Journal of the Mount Sinai Hospital*.

FIG. 1a.

FIG. 1a. Case 1. Before treatment (July 10, 1937).

FIG. 1b.

the individual requirements and makeup of the patients. As a precaution against the possible development of glaucoma, all patients past 50 years of age were routinely checked by an ophthalmologist prior to the institution of the atropine therapy.

Under the moderate-dosage atropine regimen outlined above, no disturbing reactions developed among any of the 93 patients carried at the Neurological Institute and the Vanderbilt Clinic, nor among the 19 cases in private practice. Although treatment and observation of the patients under investigation ranged from several months to four years, it can safely be stated that there was not a single instance of any reaction among them to cause concern or anxiety.

Many patients, following the preparatory period of close guidance, acquire an almost uncanny skill in the regulation of the amount of atropine solution best suited to their individual symptoms and tolerance. Nevertheless it is requisite that every patient remain under at least periodic medical supervision throughout the duration of the atropine treatment.

Results of Moderate-Dosage Atropine Treatment

The results of the moderate-dosage atropine therapy appear in summarized form in Table 2, under the headings "much improved," "slightly improved," and "unimproved." Such classification seems better suited to describe the changes in a chronic progressive disease such as postencephalitic parkinsonism,

with its varying phases and symptoms, its stationary periods and relapses, than such classifications as "virtual cure," "symptomatic cure," "remarkably improved," "much improved," "moderately improved," "slightly improved," and "unimproved," as employed by other writers. Past experience with enthusiastic reports on vaccine therapy, massive-dosage atropine therapy, hyperthermia, etc., teaches that it is much safer to underestimate than to overestimate the effects of any therapy in this condition. For the purposes of this study, the "much improved" classification will cover cases of so-called "symptomatic cure," "virtual cure," and the markedly improved; the "slightly improved" classification will include the moderately and slightly improved.

Approximately 26 per cent of the treated patients were much improved by the moderate-dosage atropine technic. "Much improved," as employed in Table 2, signifies a pronounced change for the better in a patient's appearance, action, spirit, and special disabilities, while under treatment.

TABLE 2.—EFFECTS OF MODERATE-DOSAGE ATROPINE TREATMENT

the individual requirements and makeup of the patients. As a precaution against the possible development of glaucoma, all patients past 50 years of age were routinely checked by an ophthalmologist prior to the institution of the atropine therapy.

Under the moderate-dosage atropine regimen outlined above, no disturbing reactions developed among any of the 93 patients carried at the Neurological Institute and the Vanderbilt Clinic, nor among the 19 cases in private practice. Although treatment and observation of the patients under investigation ranged from several months to four years, it can safely be stated that there was not a single instance of any reaction among them to cause concern or anxiety.

Many patients, following the preparatory period of close guidance, acquire an almost uncanny skill in the regulation of the amount of atropine solution best suited to their individual symptoms and tolerance. Nevertheless it is requisite that every patient remain under at least periodic medical supervision throughout the duration of the atropine treatment.

Results of Moderate-Dosage Atropine Treatment

The results of the moderate-dosage atropine therapy appear in summarized form in Table 2, under the headings "much improved," "slightly improved," and "unimproved." Such classification seems better suited to describe the changes in a chronic progressive disease such as postencephalitic parkinsonism,

with its varying phases and symptoms, its stationary periods and relapses, than such classifications as "virtual cure," "symptomatic cure," "remarkably improved," "much improved," "moderately improved," "slightly improved," and "unimproved," as employed by other writers. Past experience with enthusiastic reports on vaccine therapy, massive-dosage atropine therapy, hyperthermia, etc., teaches that it is much safer to underestimate than to overestimate the effects of any therapy in this condition. For the purposes of this study, the "much improved" classification will cover cases of so-called "symptomatic cure," "virtual cure," and the markedly improved; the "slightly improved" classification will include the moderately and slightly improved.

Approximately 26 per cent of the treated patients were much improved by the moderate-dosage atropine technic. "Much improved," as employed in Table 2, signifies a pronounced change for the better in a patient's appearance, action, spirit, and special disabilities, while under treatment.

TABLE 2.—EFFECTS OF MODERATE-DOSAGE ATROPINE TREATMENT

Type of Result*	No. of Cases	Percentage of Cases
Much improved	29	25.9
Slightly improved	43	38.4
Unimproved	40	35.7
Totals	112	100.0

* Among the 19 cases in private practice, 4 were much improved, 6 slightly improved, and 9 unimproved.

Case 33.—Gait freer, tremor reduced, sialorrhoea controlled.

Case 35.—Formerly confined to bed, now walking without aid; tone brighter.

Case 40.—Rigidity reduced, working for first time in four years.

Case 49.—Dystonia of jaw lessened, tone brighter, doing simple work.

Case 53.—Oculogyria partly controlled, capable of better care of home and children.

Case 55.—Sialorrhoea controlled, speech improved, depression cleared.

Case 61.—Lethargy lessened, bradykinesia improved, tone more cheerful.

Case 67.—Spasticity lessened, somnolence less, working.

Atropine was found in this investigation to bring as much symptomatic relief to the Parkinson sufferer as any other known treatment. In addition to the physical improvements, the mental stimulation afforded by the drug serves to counteract feelings of depression and discouragement which are common by-effects of any long-standing illness. Many patients under moderate-dosage atropine regimen were found to perform generally better work, whether in the calling of a shopkeeper, laborer, or artist. The women reported finding it easier to care for their homes. Even the patients with very advanced symptoms were not infrequently made more comfortable, found it possible to get about with greater ease, and were better able to attend to their personal needs, thereby lessening the burden on their families. In some patients, pains in muscles and joints were relieved as rigidity was lessened; posture was improved; lethargy was lessened to a considerable degree; speech was improved through the reduction of saliva and buccolingual rigidity; oculogyric crises were remarkably controlled in some cases, and drooling was completely checked. In a number of the cases, mild and moderate tremors responded favorably to atropine in combination with hyoscine, but advanced tremors were not found to yield to any known therapy except in rare instances. The young and recent cases, as a group, responded much more favorably to the atropine regimen than the old and long-standing cases with advanced rigidity and contractures.

The classification "unimproved" in Table 2 covers 40 cases that were too far advanced to profit from the treatment—cases with marked contractures, cases that ceased treatment because of poor tolerance, and cases that were complicated by mental disturbances. Two of the latter required commitment to a

state hospital. Some of the patients were transferred to other types of medication, such as iodide injections, hyoscine, vaccine therapy, hyperthermia treatment, rabellon and bellabulgara, without achieving material advantage. It is of added interest to note that 15 per cent of the cases listed as "slightly improved" and "unimproved" were tried on massive doses of atropine solution, in the hope of achieving further gains. Some in this group were advanced to as high as 30 drops three times a day without deriving added improvement, with the exception of Case 76. This man, although responding with increasing benefit to the higher dosage, developed such violent reactions on 35 drops, taken before retiring, that he feared to return to this medicine, and has since remained on small doses of hyoscine. His improvement consists in a slightly greater control of oculogyria with hyoscine than had been possible before atropine therapy was started. However, the change is so slight that he is classified among the unimproved.

Only in exceptional instances is it necessary or desirable to pass beyond 10-drop doses for any length of time, and at no time does it seem justifiable to pass beyond the 15-drop level. It may be considered axiomatic that if a patient fails to respond to moderate doses of atropine, he will also fail on huge doses, and will uselessly be exposed to serious reactions. The solution of such a problem lies elsewhere than in dangerous increases of atropine.

Comments on Effects—Comparisons with Other Medication

The results with moderate-dosage atropine appear highly satisfactory as long as the patients remain under treatment. The much-improved cases totaled 26 per cent, and the slightly improved, 38 per cent. These results compare favorably with appraisals of the results of massive-dosage atropine treatment, such as recorded by Hall (40 per cent greatly or definitely improved),¹⁶ or the results of Stemplinger (42 per cent definitely benefited and 58 per cent not benefited).⁴ Furthermore, it is possible that the 26 per cent much-improved result obtained with moderate doses of atropine may actually represent no smaller ratio of much-improved cases than that in the compared citations, since various writers classify cases as greatly or definitely improved in a different sense, there being no standards to apply to such changes. Never-

examined on May 6, 1942, remarkable improvement was noted.

Case 5.—A man, aged 34, single, reported that in 1929 his movements had become slowed, his neck and extremities stiff, and his eyes had begun to roll upward periodically. The eye condition had become very distressing in the past three years, lasting as long as eight hours with each paroxysm. Hyoscine, tincture of stramonium, and other forms of medication brought no relief, and he was in serious danger of losing his employment with the police department. Moderate-dosage atropine treatment was commenced in March, 1937, and within two weeks he obtained moderate relief from his eye symptoms. Within another two weeks he reached 10-drop doses, and there was complete cessation of the oculogyric crises, and a freedom of body he had not enjoyed for years, as shown in his spontaneous remark, "Now I can turn my head, and I begin to notice all the pretty girls around me." He has remained on 10-drop doses three times a day for the past four years, has worked steadily with the police department, and has not had a recurrence of the troublesome oculogyric spasms.

Case 8.—In this man, aged 35, and married, Parkinson signs appeared in 1932, with rigidity of the extremities and a mild tremor of the left arm. His condition grew worse under iodide injections and hyoscine, and in 1935 daily oculogyric spasms forced him to stop work. In April, 1937, he was started on moderate doses of atropine, and within four weeks the oculogyria was under complete control, the rigidity at a minimum, and his facial fixity had disappeared. Within three months the tremor subsided, except for slight traces when under excitement. He has continued comfortably on 8-drop doses of atropine and cares for his home and children. He has made no effort to return to work because he claims that his wife holds a much more lucrative job than it would be possible for him to obtain.

Case 10.—A man, aged 34, single, began to suffer in 1934 with increasing rigidity of the extremities, tremor in both arms, drooling of saliva, gaping of the mouth, and almost daily oculogyric crises. Hyoscine reduced the gyric paroxysms to twice weekly, but brought little change in his other symptoms. He was placed on moderate-dosage atropine April 7, 1937, and the clinical and graphic rechecks on July 31, 1937, revealed remarkable changes. The rigidity and tremors had subsided, the drooling was controlled, and the oculogyric spells have remained in check from the first month of treatment to the present day. The patient is cheerful in spirit and bright in expression.

Case 20.—A woman, aged 28, single, had influenza at the age of 12, followed by lethargy, diplopia, and narcolepsy. In 1933, oculogyric spells appeared three and four times a week, with marked trembling of the lids, increasing rigidity on the right side, and photophobia. On Decem-

ber 10, 1937, she was considered an unsuitable case for vaccine therapy because her condition had been of too long duration. She was placed on hyoscine, and on January 14, 1938, while on this drug, she became nauseous and vomited projectively, became very weak and dizzy, and the oculogyria increased in severity. The hyoscine was stopped. On January 28, 1938, she was started on moderate doses of atropine and the eye paroxysms were successfully controlled, so that on May 18, 1938, she reported not having had a single attack in two months. She became brighter, more cheerful, and was helping her mother with housework. In November, 1938, she reported a mild oculogyric paroxysm at the time of menses. On September 22, 1939, she reported not being troubled with the eye spells unless she missed her medication, and that these were mild in character. She is continuing to help her mother at home and is planning to marry shortly.

Case 26.—A violinist, aged 35, single, who had formerly been in charge of the violin department of an institute of music in the Middle West and director of a music school in New York, found himself increasingly incapacitated in his work from 1933 on. Hyoscine and other forms of medication failed to provide sufficient relief from advancing rigidity, slowness of movement and thinking, and tremor of the right hand. The condition became more distressing in the early part of 1938, with the onset of blinking of the eyes and a fear of facing audiences. His violin playing depreciated markedly, and this was the more aggravating to him because he was planning to be married. He became very despondent. He obtained employment with the WPA and on October 3, 1938, he was placed on atropine. A month later, on 8-drop doses, satisfactory progress was noted, in that rigidity was lessened and bradykinesia corrected. He looked brighter and more cheerful. On December 27, 1938, he was much improved in body and spirit. On February 7, 1939, he reported that he could play his violin much more freely and faster than before. On November 20, 1939, he reported that he had made a successful concert appearance, that he had left the WPA and was working as leader of a band, and that he had married and was living happily with his wife. Of particular interest is his statement that he had found it possible to reduce the 10-drop doses of atropine to a minimum through special programs of physical exercise, and for the past three months he has been on no medication whatever.

The cases classified in Table 2 as "slightly improved" were not without definite favorable progress, as may be noted in the following instances:

Case 31.—Gaping mouth corrected, drooling stopped, speech clearer.

Case 32.—Walking easier, spasticity lessened, tone more cheerful.

treated cases as evidence of the efficacy of a particular remedy, is to be deplored. It would be more helpful if these were qualified as to nature and duration of the employment. While a few Parkinson patients under treatment find it possible to retain, or return to, their original employment, most of those reported as working occupy themselves with simple chores, such as gardening or peddling, arranged by the benevolence of relatives and friends. It is probable that the claims of massive-dosage proponents^{2,11} ten years ago, that 60 to 70 per cent of their treated cases were returned to effective work (but have never since been heard from), possessed no greater substance than the more recent reports of 60 per cent of cases rendered self-supporting through Bulgarian belladonna root treatment.¹⁷

While the results with moderate-dosage atropine may appear promising at first glance, it must still be understood that these effects are temporary. One cannot foretell the course of these patients in the future. It is known that if the treatment were interrupted or stopped, few lasting benefits would remain. It must be realized that we are dealing with a chronic inflammatory disease, hence there should not be too much enthusiasm in reporting results, no matter what type of therapy is employed. Hall¹² comments thus: "From time to time zealous enthusiasts, carried away by the real but temporary improvements so characteristic of this chronic disease, deceive themselves and raise false hopes in others."

Acknowledging these limitations, it may nevertheless be stated that, in view of present treatment opportunities available to these chronic sufferers, moderate-dosage atropine is among the best remedies, particularly since it is free from disturbing reactions. The fact of its effectiveness in the Parkinson condition is supported not only by routine clinical observations, but also by ergographic checks upon 23 of our cases before and after a period of medication, as well as by special clinical tests (to appear in a later paper), which were found to correlate closely with the ergographic procedures.

The action of atropine, an autonomic drug, on the somatic musculature of the eyes, face, neck, trunk, and extremities, is not entirely clear. Kuntz,²⁵ in his book, *The Autonomic Nervous System*, claims that he and other workers have demonstrated the existence of direct autonomic innervation of the skeletal muscles. The experimental work of Lang-

worthy²⁶ and others, however, contradicts this contention, and attributes the autonomic effects upon somatic musculature entirely to circulatory changes. Regardless of the manner of its action, there can be little surprise that atropine is of symptomatic help in the Parkinson syndrome, since this condition is largely a pathologically exaggerated vagotonic state, as reflected in the excessive salivation, bradykinesia, bradycardia, shallow respiration, lethargy, pallor of the skin, expressionless face, etc.

The moderate-dosage atropine treatment should be tried in every case of postencephalitic parkinsonism, unless contraindications such as cerebral arteriosclerosis, hypertension, menopausal state, or threatened glaucoma exist. The treatment is inexpensive, safe, easy to obtain, and simple to administer.

Hyoscine may be added in cases with marked tremor and excitement. Hyoscine, which is the same as U. S. P. scopolamine,²⁴ was added as a supplement to atropine in 60 per cent of the cases in this investigation, and was found to be helpful and well tolerated in 35 per cent. In 40 per cent of the 112 cases, efforts were made slowly to discontinue the atropine, while at the same time increasing the hyoscine. The patients reacted poorly to the experiment, complained of returning symptoms of stiffness, sluggishness, weakness, and dizziness, and either asked for or had to be returned to the atropine regimen, with the exception of three cases. Psychologic factors were carefully considered and discounted. Further evidence that hyoscine alone is not as effective as atropine is offered in the fact that 93 per cent of all the patients under study had been on hyoscine before they turned to atropine. Hyoscine is apparently incapable of reducing the rigidity of skeletal muscles and is depressing to the higher centers, whereas atropine is stimulating in effect. Hall,¹² who probably has had as much experience with hyoscine in parkinsonism as any of the writers on the subject, makes similar comment. While hyoscine is, therefore, a good supplementary drug, it cannot successfully replace atropine, except in rare instances, in the treatment of postencephalitic Parkinson cases. In cases of true paralysis agitans, however, hyoscine should be the drug of choice.

Benzedrine sulfate was found to be of supplementary value in 5 per cent of the cases,²⁷ but was not well tolerated by others,¹³ and in not a single case was it found effective enough to replace the atropine. Physiotherapy,

theless, since moderate-dosage atropine affords marked improvement in symptoms in one case out of 4, and slight to moderate improvement in another third of the cases, it is a treatment of definite value, particularly in view of the absence of any serious reactions, and the limited therapeutic facilities available to these chronic sufferers.

A number of cases under atropine treatment, such as Cases 2, 5, 10, and 26, might be considered as symptomatic cures, but this term is a misnomer in postencephalitic parkinsonism and its use should be discouraged. Reports appear in the literature^{17*} of "virtual cures" and "symptomatic cures" with Bulgarian belladonna root treatment, whereas it is known that such improvements almost invariably disappear upon the cessation of treatment.¹⁸ For example, one would not consider a psychoneurotic patient as symptomatically cured merely because his most disturbing symptom—insomnia—was controlled by the continued use of hypnotics.

Comparison of the results of the moderate-dosage atropine treatment with conservative reports of belladonna root therapy similarly appear favorable. Thus, Hill,¹⁸ in a carefully controlled study, showed that 71 per cent of cases treated with Bulgarian belladonna root were moderately and only temporarily improved, and 29 per cent unimproved. These compare with our data of 64 per cent so improved, and 36 per cent unimproved. He furthermore makes mention of severe reactions that were encountered among his cases treated with Bulgarian belladonna root, including delirium, confusion, restlessness, and odd behavior during sleep, necessitating close attendance upon the patients during treatment. He found the Bulgarian belladonna root in no way superior to the English belladonna root. Neuwall's data¹⁹ appear slightly more favorable to Bulgarian root therapy, with 52 per cent corresponding to our much improved cases, and 25 per cent slightly to moderately improved; 5 patients died in the course of the study, and the remaining 19 per cent were unimproved. Neuwall similarly found the English belladonna root as effective as the Bulgarian. Ferrannini²⁰ reported no advantage in the Bulgarian product above and beyond those of the Italian belladonna root.

Vollmer,²¹ in a study with American belladonna root, found 53 per cent of 26 treated

cases improved subjectively and objectively. He stated that the American belladonna root was just as effective as the Bulgarian. Gayle²² treated his patients with American belladonna root, but for odd reasons called his therapy the "Bulgarian" treatment. He reported that all the symptoms in every patient, upon withdrawal of the "Bulgarian" treatment, returned to as great a degree as formerly present. Neal and Dillenberg²³ found Bulgarian belladonna root therapy resulted in 31 per cent of the cases becoming much improved, 56 per cent slightly or moderately improved, and 13 per cent remaining unimproved, while with the American belladonna root only 15 per cent were much improved, 38 per cent slightly and moderately improved, and 47 per cent unimproved, clearly implying that the American belladonna root is much inferior to the Bulgarian.

Judged on the basis of these statistical results, it would seem that moderate-dosage atropine falls somewhere between the Bulgarian and the American belladonna root therapy in effectiveness for the Parkinson syndrome. In our experience, however, the moderate-dosage atropine treatment proved far superior, since in the course of our program more than 30 patients were treated with one or the other of the belladonna root preparations, and it was found that the toxic effects of these products more than offset any gains derived, so that without exception the patients asked to be returned to atropine, or atropine supplemented by hyoscyne. Moreover, since the ingredients of the Bulgarian and American belladonna roots consist of nothing more than hyoscyamine and traces of atropine and hyoscyne, and since, according to Sollman,²⁴ the isomer, levorotatory hyoscyamine, is not different in its action on the central nervous system from racemic atropine, and only twice as strong as atropine in its peripheral effect, it would seem that no great advantages should be expected from the belladonna root preparations, above and beyond those of atropine, supplemented by hyoscyne in indicated cases. Furthermore, since a dosage of 10 drops of atropine three times a day contains 10 mg. of atropine, this should approximate the effects of 10 tablets of the belladonna root, containing less than 5 mg. of hyoscyamine, which is definitely more than the amount of the latter contained in the average daily dose of belladonna root.

The practice of some writers, of offering summary employment statistics for their

* Panegrossi reports almost 100 per cent "virtual cures" in early Parkinson cases by means of Bulgarian belladonna root.

treated cases as evidence of the efficacy of a particular remedy, is to be deplored. It would be more helpful if these were qualified as to nature and duration of the employment. While a few Parkinson patients under treatment find it possible to retain, or return to, their original employment, most of those reported as working occupy themselves with simple chores, such as gardening or peddling, arranged by the benevolence of relatives and friends. It is probable that the claims of massive-dosage proponents^{2,11} ten years ago, that 60 to 70 per cent of their treated cases were returned to effective work (but have never since been heard from), possessed no greater substance than the more recent reports of 60 per cent of cases rendered self-supporting through Bulgarian belladonna root treatment.¹⁷

While the results with moderate-dosage atropine may appear promising at first glance, it must still be understood that these effects are temporary. One cannot foretell the course of these patients in the future. It is known that if the treatment were interrupted or stopped, few lasting benefits would remain. It must be realized that we are dealing with a chronic inflammatory disease, hence there should not be too much enthusiasm in reporting results, no matter what type of therapy is employed. Hall¹² comments thus: "From time to time zealous enthusiasts, carried away by the real but temporary improvements so characteristic of this chronic disease, deceive themselves and raise false hopes in others."

Acknowledging these limitations, it may nevertheless be stated that, in view of present treatment opportunities available to these chronic sufferers, moderate-dosage atropine is among the best remedies, particularly since it is free from disturbing reactions. The fact of its effectiveness in the Parkinson condition is supported not only by routine clinical observations, but also by ergographic checks upon 23 of our cases before and after a period of medication, as well as by special clinical tests (to appear in a later paper), which were found to correlate closely with the ergographic procedures.

The action of atropine, an autonomic drug, on the somatic musculature of the eyes, face, neck, trunk, and extremities, is not entirely clear. Kuntz,²⁵ in his book, *The Autonomic Nervous System*, claims that he and other workers have demonstrated the existence of direct autonomic innervation of the skeletal muscles. The experimental work of Lang-

worthy²⁶ and others, however, contradicts this contention, and attributes the autonomic effects upon somatic musculature entirely to circulatory changes. Regardless of the manner of its action, there can be little surprise that atropine is of symptomatic help in the Parkinson syndrome, since this condition is largely a pathologically exaggerated vagotonic state, as reflected in the excessive salivation, bradykinesia, bradycardia, shallow respiration, lethargy, pallor of the skin, expressionless face, etc.

The moderate-dosage atropine treatment should be tried in every case of postencephalitic parkinsonism, unless contraindications such as cerebral arteriosclerosis, hypertension, menopausal state, or threatened glaucoma exist. The treatment is inexpensive, safe, easy to obtain, and simple to administer.

Hyoscyne may be added in cases with marked tremor and excitement. Hyoscyne, which is the same as U. S. P. scopolamine,²⁴ was added as a supplement to atropine in 60 per cent of the cases in this investigation, and was found to be helpful and well tolerated in 35 per cent. In 40 per cent of the 112 cases, efforts were made slowly to discontinue the atropine, while at the same time increasing the hyoscyne. The patients reacted poorly to the experiment, complained of returning symptoms of stiffness, sluggishness, weakness, and dizziness, and either asked for or had to be returned to the atropine regimen, with the exception of three cases. Psychologic factors were carefully considered and discounted. Further evidence that hyoscyne alone is not as effective as atropine is offered in the fact that 93 per cent of all the patients under study had been on hyoscyne before they turned to atropine. Hyoscyne is apparently incapable of reducing the rigidity of skeletal muscles and is depressing to the higher centers, whereas atropine is stimulating in effect. Hall,¹² who probably has had as much experience with hyoscyne in parkinsonism as any of the writers on the subject, makes similar comment. While hyoscyne is, therefore, a good supplementary drug, it cannot successfully replace atropine, except in rare instances, in the treatment of postencephalitic Parkinson cases. In cases of true paralysis agitans, however, hyoscyne should be the drug of choice.

Benzedrine sulfate was found to be of supplementary value in 5 per cent of the cases,²⁷ but was not well tolerated by others,¹³ and in not a single case was it found effective enough to replace the atropine. Physiotherapy,

particularly passive and active exercise and massage, was found very helpful for the rigidity, as were high-calorie diets and calcium for the tremors. Ephedrine, nembital, gyn-ergen, phenobarbital, dilantin, bromides, thyroid, pituitary, and vitamin B₁ were tried, but not one of them added materially to the atropine factor.

Summary

The investigation sought to establish to what extent moderate-dosage atropine could obviate the violent reactions of the massive-dosage treatment, and yet retain the therapeutic advantages of the latter. Details of the method of administration, the common and unusual reactions, and the effects of the moderate-dosage atropine treatment are reviewed in a group of 112 Parkinson cases. Comparisons are also afforded between the results of this treatment and those of massive-dosage atropine treatment, as well as those obtained with the various preparations of belladonna root, hyoscine, etc.

The findings reveal that moderate-dosage atropine treatment is free from disturbing reactions, and its results compare favorably with those of massive-dosage atropine treatment and other forms of therapy.

Clinical observations indicated that 26 per cent of the 112 cases of Parkinson's syndrome were much improved, and 38 per cent slightly to moderately improved. The clinical impressions as to the effectiveness of the treatment were supported in 23 cases by ergographic records taken before and after atropine treatment, as well as by special clinical tests which were found to correlate in precision with the ergographic procedures. Atropine was found particularly helpful in the young and recent cases.

Moderate-dosage atropine is a desirable remedy in the armamentarium for the treatment of postencephalitic parkinsonism. It is inexpensive, effective, easy to obtain, safe to use, and simple to administer when the routine is comprehended. It is also of value as a replacement therapy in chronic encephalitis, when patients tire of years of sodium iodide injections, hyoscine, vaccine therapy, hyperthermia, etc. It is of greater help in 35 per cent of the cases when combined with hyoscine, and in 5 per cent of the cases when combined with benzedrine sulfate. Interrupting the treatment produces mild withdrawal reactions, and stopping the treatment leaves few lasting benefits.

Conclusions

1. The original Roemer treatment of parkinsonism with massive doses of atropine has been found unnecessary, dangerous, and of no special advantage.

2. Moderate-dosage atropine therapy is free from disturbing reactions, and its results compare favorably with those of massive-dosage atropine therapy, as well as those obtained with the various belladonna root preparations.

3. The moderate-dosage atropine regimen is a most economical, simple, and safe treatment to undertake, if reasonable precautions are taken.

4. Moderate-dosage atropine treatment should be the one of choice for Parkinson cases, supplemented by hyoscine in selected situations. Only in cases refractory to atropine should the more expensive, and apparently more toxic, proprietary belladonna root preparations be employed, since they possess no ingredients of structure or function above and beyond those of atropine and hyoscine. The use of massive-dosage atropine therapy is hardly justified at any time, in view of the violent reactions produced.

A COMPARISON OF SYNTHETIC AND NATURAL BELLADONNA ALKALOID COMPOUNDS IN THE TREATMENT OF PARKINSONISM

HERMANN VOLLMER, M.D., New York City

NEAL and Dillenberg¹ reported that their "results with bellabulgara were far superior to those with rabellon" in the treatment of chronic encephalitis: "furthermore, the toxic effects with rabellon were more frequent, more severe, and occurred with a smaller dosage."

Bellabulgara is a tablet containing 0.4 mg. of the total alkaloids extracted by white wine from selected roots of Bulgarian belladonna. Rabellon is a synthetic preparation containing 0.5 mg. of alkaloids per tablet in the following combination: hyoscyamine hydrobromide, 0.4507 mg.; atropine sulfate, 0.0372 mg.; and scopolamine hydrobromide, 0.0119 mg. In a previous publication² the theory, pharmacologic development, and clinical results obtained with this synthetic preparation were outlined. The latter are incompatible with the statements of Neal and Dillenberg.

Though previously² rabellon had been compared with and found at least equivalent to natural Bulgarian belladonna root extracts, a new comparative study of bellabulgara and rabellon was carried out by the author. A group of 15 patients who had been treated over a period of from three to twenty months with rabellon were shifted to the natural belladonna preparation as soon as they appeared dissatisfied with the therapeutic results of the former, or disappointed because no further improvement could be achieved. The patients were informed that they were to take bellabulgara, and in three cases vinobel, which is a similar natural belladonna preparation; these were prescribed as "new remedies which are supposed to be more effective than rabellon and therefore worth a trial." Since the considerably higher price of bellabulgara might have been a psychologic factor, I wish to mention that most of these patients who had to buy rabellon were furnished with free samples of the natural drugs. After a trial of from one to four weeks, the patients were first questioned as to their impressions and preferences for either one of the preparations, and subsequently examined. It was left entirely up to the individual patient which preparation he wanted to continue.

Table 1 contains the results of this comparative study. It is evident that bellabulgara did not prove superior to rabellon.

Fourteen of the 15 patients preferred rabellon, all 15 patients at their own request continued treatment with rabellon. There was no indication whatsoever that rabellon caused more side-effects. None of the patients was objectively improved by subsequent therapy with bellabulgara; most of them claimed to feel worse while taking the natural preparation.

Case 7 was particularly interesting. This was a woman, 50 years old, with chronic encephalitis of eight years' duration, who had been treated with bellabulgara since July, 1940. At first it seemed to help, but later it proved ineffective. This patient was first seen October 18, 1940, and was at this time taking 10 tablets of bellabulgara per day. She showed marked bilateral tremor, moderate rigidity, retropulsion and propulsion, and could not walk one block. She had slight dryness of the throat and slightly blurred vision. She had been unable to write for the past two years. A sample of her handwriting on October 18, 1940, is shown in Fig. 1. The patient was shifted to 9 tablets of rabellon. Eight days later her condition had definitely improved, the side-effects had decreased, she felt better, walked two blocks, and wrote considerably better (Fig. 2). On November 9, 1940, the dosage was increased to 10½ tablets of rabellon per day. She felt much better, had no side-effects, the rigidity had disappeared, the tremor was markedly relieved, she easily managed to walk six blocks without any propulsion, and her handwriting was practically normal (Fig. 3).

Discussion

The discrepancy between the results of Neal and Dillenberg and those reported here calls for an explanation. It is not merely a practical question of the superiority of one preparation over another, but a more fundamental pharmacologic question. To resort to the assumption that natural compounds are frequently more effective than synthetic preparations is not satisfactory. It is true that, for example, codliver oil, in some instances, as in relation to leg weakness of chickens is more effective than irradiated ergosterol. This is certainly not merely because codliver oil is a

Dr. H. Vollmer.
25 Central Park West
New York City

Nov. 9, 1940

Dear Dr. Vollmer.

I am well & pleased with the results from your treatment so far, and at your suggestion, you have my authority to use my signature for "scientific" purposes only, showing the improvement in my writing.

Very truly yours,

Helena M. Krueger.

FIG. 3. Handwriting of same patient, showing remarkable improvement twenty-two days after change of medication (at this time taking 10 1/2 tablets of rabellon per day).

natural compound, but because codliver oil contains mainly vitamin D₃, which is different from and more effective in chicken rickets than vitamin D₂. Thus advancing knowledge usually replaces mere speculation.

Therefore, if the observations of Neal and Dillenberg were to be confirmed by others, we should not necessarily have to explain such results on the basis of superiority of natural compounds. Pharmacodynamic synergism is

a pharmacologic fact. However, the natural and the synthetic preparations have a certain similarity and therefore would be expected to exert analogous synergisms. If, nevertheless, bellabulgar were superior to rabellon, we should resume the pharmacologic studies of belladonna roots and look for new and as yet unknown components. The traces of belladonnine and atropamine which may occasionally be present in belladonna roots certainly do not offer a convincing explanation for a superior effect. In fact, I could not confirm the results of Neal and Dillenberg. Furthermore, other investigators of this subject corroborated my findings in personal communications. Recently, Price and Merritt³ arrived at similar conclusions.

There are two clues to explain the observations of Neal and Dillenberg. First, Dillenberg, in his discussion remarks, which did not appear in the publication, indicated that the highest dose of rabellon given in the one group was 9 tablets per day, as compared with the maximum dose of 18 tablets of bellabulgar administered in the other group of patients. He further stated that higher doses of rabellon did not further improve and were not tolerated. This is in contrast to my observations. A considerable percentage of my patients tolerated and needed more than 9 tablets of rabellon to obtain optimum results. A daily dose of about 20 tablets was no exception and never caused toxic manifestations. Patients in an advanced stage of chronic encephalitis, as among those treated by Neal and Dillenberg, in general need larger doses than do mild cases of short duration. Consequently, doses of not more than 9 tablets of rabellon appear insufficient for many cases and less adequate than doses of up to 18 tablets of bellabulgar as administered in the comparative group of patients. The only conclusion permissible from the comparative study of Neal and Dillenberg, therefore, would be that bellabulgar in adequate dosage is more effective than rabellon in inadequate dosage.

A second factor has to be taken into consideration. An analysis of Table 1, and the observation in Case 7, would justify the conclusion that rabellon is superior to bellabulgar. I do not wish to commit myself to such a statement. Every student of chronic encephalitis knows to what extent some symptoms of parkinsonism, particularly the disturbance of initiating movements, can be influenced by psychotherapy. Drug therapy may veil or be a vehicle of such psychothera-

* After repeated change, rabellon was found to be better.

peutic influences. It is obvious that the efficacy of a drug on chronic encephalitis depends not only on its real pharmacologic effect but also, to a certain extent, on the attitude of the physician and the way he presents the drug to the patient. As between such similar preparations, the one that the individual physician believes in, and is more interested in, is apt to achieve the better clinical results. I certainly tried to eliminate this psychic factor in the present comparative study.

Finally, I believe that it will lead to more conclusive results if the symptomatic effects of two preparations are compared by interchanging these drugs in equivalent or optimum dosage in the same patients, instead of in the manner adopted by Neal and Dillenberg. These investigators placed their patients in two groups of similar age and severity of condition; they treated the one group with bellabulgar, the other with rabellon,

and compared the results in the groups respectively. This method of comparison seems to involve more possibilities of error.

Conclusion

In 15 patients with Parkinson's syndrome, a comparison of natural (bellabulgar) and synthetic (rabellon) belladonna alkaloid compounds did not reveal any appreciable difference in therapeutic value. In some cases, rabellon seemed to be superior.

Contradictory reports of Neal and Dillenberg are ascribed to a difference in dosage of the two preparations, and possibly to a psychologic factor.

In every mental institution, tuberculosis is a problem of the first order. Of the deaths from tuberculosis in the United States, 5.2 per cent occur in mental hospitals, while only 15.9 per cent are in tuberculosis hospitals.—M. Pollak, M.D., et al, in *Amer. Rev. Tub.*

A medical paper advances the theory that "man is slightly taller in the morning than he is in the evening." We have never tested this, but we have certainly noticed marked tendency to become "short" toward the end of the month. —The Mississippi Doctor

CLINICAL CONSIDERATIONS OF POISONINGS BY SOME OF THE CHLORINATED HYDROCARBONS

HENRY FIELD SMYTH, M.D., Dr.P.H., Philadelphia

IN THIS paper we shall limit our discussion to the more volatile members of the chlorinated hydrocarbon group and to those most usually met with in industrial exposures, where poisoning is principally due to inhalation of vapors or sprays. For the sake of reasonable brevity, we shall not consider the chlorinated naphthalenes or halowax group, which act primarily as skin irritants, but which are also capable of producing systemic poisonings. The effects of these materials have been fully reported by members of the New York State Department of Labor and the Harvard group.

Of the group to be considered here, the most important, from the standpoint of extent of use, is carbon tetrachloride or tetrachloromethane. Among the saturated compounds we must also consider methyl chloride (CH_3Cl), ethyl chloride ($\text{C}_2\text{H}_5\text{Cl}$), chloroform (CHCl_3) or trichloromethane (which is of more interest in medicine than in industry), tetrachloroethane ($\text{CHCl}_2\text{CHCl}_2$), and pentachlorethane ($\text{CCl}_3\text{CHCl}_2$), the last two being decidedly the most toxic of the entire group. We also at times meet with methylene dichloride or dichloromethane (CH_2Cl_2), and ethylene dichloride or dichlorethane ($\text{CH}_2\text{Cl}\text{CH}_2\text{Cl}$). Among the unsaturated compounds trichlorethylene (CHCl.CCl_2) and tetrachlorethylene (C_2Cl_4), or perchlorethylene as it is frequently called, are the most often used, although we also occasionally meet with dichlorethylene (CHCl.CHCl).

In the discussion of these materials we shall stress only the clinical features of poisonings, including prophylaxis, diagnosis, prognosis, and treatment, as the phases that are of particular interest to physicians in industry and to general practitioners. At the outset we wish to emphasize the importance of knowing in some detail the industrial exposures (not just *where* the man works, but especially *how*) possibly affecting workers who come to physicians for advice.

General Considerations

As a class, the gaseous hydrocarbons them-

Director, Smyth Laboratories, Philadelphia. Formerly professor of Industrial Hygiene, University of Pennsylvania.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 29, 1941.

selves usually act more or less specifically on nervous tissues, but the chlorinated hydrocarbons, especially the saturated compounds, act less specifically on nervous tissue and more definitely on the heart, respiratory tract, and glandular organs, especially the liver and kidneys, and at times the pancreas and adrenals. Continuing exposures produce cardiac muscle depression and degeneration of internal organs. The unsaturated compounds produce less of these organ degenerations and more of the specific nerve tissue changes characteristic of the effects of the unhalogenated compounds.

In high concentrations, almost all of the entire group are anesthetic in action and, if exposure continues, may produce pulmonary edema, coma, and cardiac death. Because of this action, the first consideration in poisonings from any chlorinated hydrocarbon is immediate and continued removal from further exposure, with fresh air and absolute rest.

It is also very important that where men are asked to work with these materials, pre-employment examinations should be insisted upon, and all workers with heart, circulatory, or respiratory defects, or damage to liver or kidneys, be excluded from such exposures. Since alcohol consumption increases the hazard, alcohol addicts, especially those indulging in acute excesses, should be excluded from exposure. For workers with the unsaturated compounds of the group, nervous stability, both central and peripheral, is also important.

Usually the chlorinated hydrocarbons have distinctive odors easily detectable by the average person. It is always best to determine the hazard by chemical measurements of vapor concentrations in working areas; but where such tests are not available, the average person, entering from a fresh atmosphere, can detect potential danger by the odor before other effects, such as dizziness, etc., need be felt.

Unsaturated Compounds

As already stated, the unsaturated compounds are less apt to act on glandular organs and heart muscle and so are less apt to produce easily recognizable chronic effects, although the idea that this necessarily makes them innocuous in any but very heavy acute expo-

tures is erroneous. My own personal experience with the chlorinated hydrocarbons is limited to trichlorethylene and perchlorethylene in the unsaturated group, and carbon tetrachloride in the saturated group.

Dichlorethylene.—Hamilton¹ reports a fatality in the case of a rubber worker entering a vat containing rubber dissolved in dichlorethylene. No details are given, and no other cases seem to have been reported in the literature.

Trichlorethylene.—This substance is very widely used as a degreasing agent in connection with metals, for the extraction of fats and oils, as a nonflammable dry cleaning agent, and in various ways. It may be used alone or in combination with other more or less toxic materials, especially in mixtures with trade names giving no true indication of their chemical compositions. As with all mixed chemical hazards, typical pictures may be much confused and not infrequently the combined action of two or more toxic materials may be greater than the additive total of the individual effects.

Most of the industrial poisonings from trichlorethylene have been acute and in many cases fatal, and some workers have implied that there is little or no danger from chronic poisoning when a reasonably pure material is used, as is the case in this country. We feel definitely that this is a mistaken idea, as various cases of chronic ill effects have been reported; and although trichlorethylene is undoubtedly less toxic, volume for volume, than are carbon tetrachloride and other saturated chlorinated hydrocarbons, the very fact that it does not usually produce much effect on the glandular organs, such as liver and kidneys, but acts principally on central and peripheral nervous tissue, makes its early effects less easily recognizable, the nervous manifestations being more easily overlooked in early stages or attributed to psychic or other causes. We therefore feel that it is especially important to protect workers from this potential harm, which is less apt to be recognized than is liver or kidney degeneration.

Because of its depressant action on cranial nerves, trichlorethylene has been used as a curative for trigeminal neuralgia as well as for angina pectoris. Its action is, however, in no sense curative, but merely palliative. For these conditions it has been given by inhalation, from 20 drops to 1 cc. at a time; but so used it is an edged tool. Isenschmid and Kunz² report such use of it for angina pectoris as causing a severe neuritis, papillary dis-

turbances, polyneuritis of all extremities with loss of reflexes, reduced skin sensitivity of a persistent nature, and permanently impaired vision. Eichert³ reports 3 cases of therapeutic poisoning with central nervous system disturbances, such as disorientation, confusion, amnesia, ataxia, and trigeminal area analgesia. Kunz and Isenschmid⁴ also report 7 cases of eye injury. Both acute and chronic injury may lead to prolonged after-effects of a general nature, with psychic and gastric disturbances, anemia, and poor vision due to retrolbulbar neuritis. Gerbis⁵ in 1930 reported 2 cases of angina pectoris occurring from inhalation during degreasing operations. The New York State Department of Labor and Industry *Bulletin* for November, 1937,⁶ reports three users complaining of fatigue, with gastrointestinal and central nervous symptoms, including fine tremors of eyelids and hands.

Although many more cases of acute poisonings (at times severe or fatal, but often with only temporary subjective symptoms) have been reported than of chronic poisonings, we feel that the report of Taylor⁷ in 1936, based on exposures of a limited number of rabbits and two dogs for up to six months to from 500 to 3,000 parts per million, and showing no effect on growth, and no degeneration of liver or kidneys, is rather misleading. He states that single exposures only are important, although he made no examinations to detect nerve damage. Lande, Derville, and Nun⁸ did produce hepatic and renal changes in animals.

McNally⁹ reports a case of alleged phosgene poisoning from inhalation of fumes from an open unventilated degreasing tank coming in contact with an open flame used to heat the tank. His patient had disturbed vision, chest symptoms, low blood pressure, and liver tenderness. Drinker,¹⁰ commenting on an abstract of this report, says that the phosgene factor was not proved, and I agree with him. It is known that both trichlorethylene and carbon tetrachloride will produce phosgene in the presence of an open flame, but in appreciable amounts only where the oxygen supply is limited and glowing hot metal surfaces are present, as is often the case when fire extinguishers are used in confined spaces. In these cases, toxic gases and fumes from incomplete combustion are also present and may predominate in the picture. Phosgene as a war gas was recognized as a very active corrosive irritant producing its effects locally in the lungs when, on coming in contact with lung

moisture, it breaks up to form nascent hydrochloric acid. It is in no sense a systemic poison, although it is a powerful destructive agent acting locally and leaving lasting or permanent damage.

Like almost any fat solvent, liquid trichlorethylene may produce a dermatitis on exposed surfaces or may act as a contributing cause in dermatitis produced by infective agents. Ramel¹¹ claims that trichlorethylene can have a specific catalytic action in the development of allergic dermatitis of bacterial origin. He reports such action in a case of hemolytic streptococcic infection. We have seen a case of obstinate dermatitis, in a dry cleaner using "trichlor," wrongly diagnosed by several dermatologists as a specific effect, while we found it, on careful examination, to be in reality a trichophytn eruption originating from a long-standing interdigital foot infection not directly connected with exposure and not looked for by previous examiners. This was naturally aggravated by constant wetting with the solvent. Indeed, in every outbreak of apparent industrial dermatitis the possible presence of a primary skin fungus or bacterial infection must be taken into consideration.

Jordi,¹² in Switzerland, calls attention to the habit-forming potentialities of this material in the case of youths using it for hypnotic purposes and developing a craving for it. Another potential harm from continuing exposure is shown by Kubo,¹³ in Japan, who injected rabbits with trichlorethylene, producing diminished typhoid agglutinin formation. This action, however, he found, was offset by glucose or levulose injections.

From what has been said, it will be evident that trichlorethylene workers should have pre-employment physical examinations to detect nervous pathology or weakness and circulatory disturbances. They should have an adequate carbohydrate diet, should be protected at work by adequate exhaust ventilation or closed processes to keep exposures within safe limits (below a 200 parts per million daily average for continuous work), and should be examined periodically to detect circulatory or nerve damage and damage in liver or kidneys, even though the latter is unusual.

Tetrachlorethylene.—We shall consider one more of the unsaturated compounds of the chlorinated hydrocarbons, namely, tetrachlorethylene, or perchlorethylene, recently coming into use in this country as a dry cleaner, as a constituent of dry cleaning soaps,

and as a rosin solvent for fabric and fiber impregnation. Its high boiling point, 121 to 122 C., makes it very effective as a degreasing agent.

This seems to be the least toxic compound among the entire group under consideration, although it likewise must not be considered as entirely free from menace. Unlike trichlorethylene, it has produced no nervous tissue manifestations, and, so far, no reported cases of chronic poisoning in man. Extended work by Carpenter,¹⁴ carried on at the University of Pennsylvania, showed that for animals no glandular lesions comparable to those observed with carbon tetrachloride were produced, even with exposures up to 470 parts per million for one hundred and fifty days—but only cloudy swelling of liver and kidney and splenic congestion, with increased pigment deposit. No blood changes were found, and no specific urine changes were observed.

In high concentrations, like others of the group, it is an anesthetic. Carpenter found that in human exposures, of volunteers from our staff, 4,600 parts per million produced mental fogging, dizziness, and fainting in five minutes; 2,000 parts per million, the same effects in seven minutes; 1,000 parts per million, light inebriation after one and a half hours; and 500 parts per million, no discomfort after two hours. When used as a defatting or degreasing agent it may cause dermatitis, or may exaggerate a skin infection already present. We found no evidence of toxic action in the dry cleaning industry, although in one plant where this material was being used in an antiquated machine we found a concentration of 280 parts per million during the 34-minute cycle, with a peak during a 1-minute unloading period of 4,636 parts per million. The operator had been employed there for two years and reported no ill effects, other than some discomfort on humid days. As a result of animal exposures, field observations, and experimental human exposures, we put the safe limit of concentration as somewhere between 100 and 500 parts per million, feeling that a closer approximation must await further human experience. We found no distinctive or pathognomonic signs or symptoms to indicate beginning poisoning, and so have no suggestion as to evidence of harm or as to specific treatment, other than, as with other compounds of the group, if harm is suspected, immediate removal from exposure and symptomatic treatment. We know of no reports of authentic cases of industrial poisoning from perchlorethylene.

Saturated Compounds

As previously stated, the saturated compounds are more likely to produce chronic poisoning, with evidence especially of hepatic or renal damage.

Methyl Chloride.—Methyl chloride, the simplest of this group, has been used principally as a refrigerating agent, and poisonings from it are mostly acute or subacute, and due to accidental leakage. On absorption this compound is decomposed to methanol and hydrochloric acid, and poisoning is due principally to the methanol formed. As methanol itself is nonreactive and very slowly eliminated, severe poisoning may develop from continuing exposure to small concentrations. Such poisoning is of slow development and recovery is slow. Gastrointestinal disturbances, as vomiting, diarrhea, and abdominal pain, may accompany excitement and even epileptiform convulsions. Most of the cases of methyl chloride poisoning reported in this country were in 1927 and 1929, in the making, installation, and use of multiple-unit refrigeration systems. Baker,¹⁵ in 1927, reported 27 cases with visual disturbances, ptosis, fine tremors, and staggering gait. Symptoms cleared up very slowly, but all recovered. In 1929 Kegel et al.¹⁶ reported 29 cases with 10 deaths, three of the nonfatal cases being industrial. Usually temperature, pulse, and respiration were increased; there was oliguria or complete suppression of urine for thirty-six to forty-eight hours. Evidence of acute nephritis was found in about half of the cases. Very few cases have been reported recently. Weinstein,¹⁷ in 1937, reported 2 cases with mild headache, fatigue, etc., with both recovery. Treatment in these cases should be symptomatic.

Ethyl Chloride.—Ethyl chloride, or monochlorethane, is used as an anesthetic and as a solvent and refrigerant. It is somewhat less toxic than methyl chloride, but its use as an anesthetic produces more excitement and restlessness. In the system it forms ethyl alcohol and hydrochloric acid. Action, therefore, is more rapid than in the case of methyl chloride and recovery is also more rapid. I have no record of industrial poisonings.

Methylene Dichloride.—Methylene dichloride, or dichlormethane, was formerly used as an anesthetic, but this has been discontinued because of fatalities. It has been used industrially as a solvent and paint remover, and in Europe, at least, in the artificial silk industry. As far as my records go, no cases of industrial methylene dichloride poisoning have been re-

ported in this country. Browning,¹⁸ in England, quotes Zernik to the effect that when free from impurities and used under conditions of good ventilation it is practically harmless, although Collier¹⁹ reports 2 cases with subjective symptoms only, as irregular but severe pains in legs and arms, hot flashes, headache, vertigo, mental dullness, clouded vision, anorexia, precordial pain, rapid pulse, etc.

Ethylene Dichloride.—We do find occasional reference to poisoning from ethylene dichloride, or dichlorethane, but although Lehmann classes it as more toxic than the higher members of the group and carbon tetrachloride, the cases of industrial poisonings from this material are very few. It has been used as a dry cleaning agent, as a solvent for crepe rubber, a perfume extractive, an insecticide, a refrigerating agent, and a solvent for cellulose acetate. Wirtschafter and Schwartz²⁰ report 3 cases of acute poisoning in workers cleaning knitting yarn with ethylene dichloride by dipping the yarn in an open vat and wringing it dry by hand. After four hours they developed dizziness, nausea, vomiting, muscular weakness, trembling, and epigastric cramps, followed by a severe dermatitis. They developed a leukocytosis, and showed a low blood sugar, suggesting liver damage. All recovered with calcium and carbohydrate therapy. All this is suggestive of carbon tetrachloride damage, although the limited animal work on record reports no liver or kidney degeneration. Browning²¹ states that it apparently has a specific irritating effect on the cornea in animals.

Chloroform.—Chloroform, or trichlormethane, is little used industrially in this country, and we have no record of industrial chloroform poisoning. Therefore we shall pass over discussion of it.

Carbon Tetrachloride.—This brings us to the consideration of carbon tetrachloride, or tetrachlormethane, the most widely used and most intensively studied of the chlorinated hydrocarbons. Because of its widespread use and because for some time it was used freely in open processes with no realization of its potential harmfulness and with no special effort to protect workers, it has been responsible for more cases of poisoning, some of them serious or even fatal, than has any other member of this group. The principal uses of this material are as a dry cleaner, as a degreasing agent, and as a fire extinguisher. Its great advantage over gasoline and naphtha in dry cleaning is its noninflammability. Even with careless and ignorant use of it resulting

moisture, it breaks up to form nascent hydrochloric acid. It is in no sense a systemic poison, although it is a powerful destructive agent acting locally and leaving lasting or permanent damage.

Like almost any fat solvent, liquid trichlorethylene may produce a dermatitis on exposed surfaces or may act as a contributing cause in dermatitis produced by infective agents. Ramel¹¹ claims that trichlorethylene can have a specific catalytic action in the development of allergic dermatitis of bacterial origin. He reports such action in a case of hemolytic streptococcic infection. We have seen a case of obstinate dermatitis, in a dry cleaner using "trichlor," wrongly diagnosed by several dermatologists as a specific effect, while we found it, on careful examination, to be in reality a trichophyton eruption originating from a long-standing interdigital foot infection not directly connected with exposure and not looked for by previous examiners. This was naturally aggravated by constant wetting with the solvent. Indeed, in every outbreak of apparent industrial dermatitis the possible presence of a primary skin fungus or bacterial infection must be taken into consideration.

Jordi,¹² in Switzerland, calls attention to the habit-forming potentialities of this material in the case of youths using it for hypnotic purposes and developing a craving for it. Another potential harm from continuing exposure is shown by Kubo,¹³ in Japan, who injected rabbits with trichlorethylene, producing diminished typhoid agglutinin formation. This action, however, he found, was offset by glucose or levulose injections.

From what has been said, it will be evident that trichlorethylene workers should have pre-employment physical examinations to detect nervous pathology or weakness and circulatory disturbances. They should have an adequate carbohydrate diet, should be protected at work by adequate exhaust ventilation or closed processes to keep exposures within safe limits (below a 200 parts per million daily average for continuous work), and should be examined periodically to detect circulatory or nerve damage and damage in liver or kidneys, even though the latter is unusual.

Tetrachlorethylene.—We shall consider one more of the unsaturated compounds of the chlorinated hydrocarbons, namely, tetrachlorethylene, or perchlorethylene, recently coming into use in this country as a dry cleaner, as a constituent of dry cleaning soaps,

and as a rosin solvent for fabric and fiber impregnation. Its high boiling point, 121 to 122 C., makes it very effective as a degreasing agent.

This seems to be the least toxic compound among the entire group under consideration, although it likewise must not be considered as entirely free from menace. Unlike trichlorethylene, it has produced no nervous tissue manifestations, and, so far, no reported cases of chronic poisoning in man. Extended work by Carpenter,¹⁴ carried on at the University of Pennsylvania, showed that for animals no glandular lesions comparable to those observed with carbon tetrachloride were produced, even with exposures up to 470 parts per million for one hundred and fifty days—but only cloudy swelling of liver and kidney and splenic congestion, with increased pigment deposit. No blood changes were found, and no specific urine changes were observed.

In high concentrations, like others of the group, it is an anesthetic. Carpenter found that in human exposures, of volunteers from our staff, 4,600 parts per million produced mental fogging, dizziness, and fainting in five minutes; 2,000 parts per million, the same effects in seven minutes; 1,000 parts per million, light inebriation after one and a half hours; and 500 parts per million, no discomfort after two hours. When used as a defatting or degreasing agent it may cause dermatitis, or may exaggerate a skin infection already present. We found no evidence of toxic action in the dry cleaning industry, although in one plant where this material was being used in an antiquated machine we found a concentration of 280 parts per million during the 34-minute cycle, with a peak during a 1-minute unloading period of 4,636 parts per million. The operator had been employed there for two years and reported no ill effects, other than some discomfort on humid days. As a result of animal exposures, field observations, and experimental human exposures, we put the safe limit of concentration as somewhere between 100 and 500 parts per million, feeling that a closer approximation must await further human experience. We found no distinctive or pathognomonic signs or symptoms to indicate beginning poisoning, and so have no suggestion as to evidence of harm or as to specific treatment, other than, as with other compounds of the group, if harm is suspected, immediate removal from exposure and symptomatic treatment. We know of no reports of authentic cases of industrial poisoning from perchlorethylene.

increased resistance. We have found no workers continuing in carbon tetrachloride work for over five years who showed any evidences of harmful effect. We have examined men working in the manufacture of this material for twenty years or more who gave histories of rather severe poisoning in the first years, necessitating temporary discontinuance of work, but who had had no symptoms for ten or fifteen years. This bears out our findings in animal exposures, where animals exposed for two months to concentrations producing severe hepatic and renal damage in other animals of the same group, were, after a two months' rest period, completely recovered, and were then little if at all affected by acute exposures severe enough to produce grave lesions in normal animals. We found that regeneration of damaged liver and renal tissue was the usual occurrence.

Severe, and in some cases fatal, poisonings have been associated with the use of carbon tetrachloride as a fire extinguisher, but almost always where use was in confined spaces. Under these conditions, with very limited air supply, in the presence of glowing metal surfaces, phosgene gas will be formed and will contribute to the picture of acute lung damage; but here there is, at the same time, production of carbon monoxide, chlorine, and hydrochloric acid fume, which also contributes to the total damage. We therefore feel that the danger of phosgene effect has been overrated, and in no sense can carbon tetrachloride poisoning be attributed to phosgene formation in the body. Phosgene can certainly be excluded as a cause of the hepatic and renal damage.

Diagnosis of chronic poisoning from carbon tetrachloride is based on the symptoms previously referred to, with the finding of a high icteric index (over 8), a high indirect van den Bergh test (over 0.2 mg. per hundred cubic centimeters), and a high blood nitrogen value. Domart feels that the degree of urea excretion following restoration of urinary secretion after the anuria of the renal types has a direct bearing on prognosis. If the urea accumulated in the anuric phase is rapidly eliminated, with early return of urinary urea to normal, the prognosis is always good.

Domart summarizes the symptoms of the hepatorenal forms as follows: general discomfort and headache preceding digestive disturbances; possible epistaxis; light jaundice; after forty-eight hours, nephritis with oliguria or anuria; headache, insomnia, and agitation, followed by torpor and prostration.

Edema is variable. Anuria may last from three to five days. With return of urinary secretion, albuminuria decreases rapidly, followed by decrease in urinary urea. With this development, prognosis is good. Pure hepatic forms without nephritic symptoms usually recover with no sequelae.

Prophylaxis consists in control of exposures, maintenance of a high carbohydrate and high calcium diet, and pre-employment physical examinations, with exclusion from work of alcoholics, those with cardiac weakness, and those with any evidence of hepatic or renal injury. Physical examinations should include tests for icteric index, indirect van den Bergh tests, and the usual blood and urine examinations.

Workers continually exposed to any but minimal concentrations should be examined at least semiannually, as above. They should be advised as to an adequate diet as indicated, and as to abstinence from alcoholic excess. Constipation should be avoided. Wirtschafter²⁴ has reported concentric constriction of visual fields as a sign of carbon tetrachloride poisoning, and our field tests seem to confirm this; therefore, this test might well be included in the periodic examination program.

Treatment should be based on maintenance of blood sugar and calcium. G. G. Davis²⁵ advises, in severe cases, the administration of intravenous glucose, as calcium gluconate, with pushing of carbohydrates by mouth when the stomach permits, absolute rest in bed, and liquid diet.

Domart advises, in the renal cases, hot compresses to the lumbar regions, or cupping, and a diet low in salt as a precaution against edema, which frequently develops. In pronounced oliguria he advises intravenous injections of 30 per cent calcium gluconate solution—possibly two daily injections of 100 cc. each—and warns against giving the usual diuretics. Ten to 20 Gm. of sodium bicarbonate by mouth may be given to restore a lowered alkali reserve.

One precaution is essential. In no case should adrenalin injections be given, as they may produce a fatal ventricular fibrillation. This reaction has been pointed out by Dautrebande²⁶ in cases of benzol poisoning.

Tetrachlorethane, Pentachlorethane.—Tetrachlorethane and pentachlorethane are without doubt the most toxic of the chlorinated hydrocarbons. The former produced numerous cases of severe poisoning and death at the time of World War I, due to use of it as a solvent for airplane wing dope, but at present it is

in severe or fatal poisonings, it has been responsible for far fewer fatalities than have petroleum products. As manufactured and marketed in this country, carbon tetrachloride is a remarkably pure product and we need give no consideration to the effects of impurities in it.

In high concentrations it is like all of the group, an anesthetic and cardiac depressant, and deaths from acute exposure are cardiac deaths. If the worker survives the acute exposure there may be a delayed toxic action, with pulmonary edema, cardiac depression, and nephritic symptoms with oliguria or even complete suppression of urine. In the case of lighter exposures the chest symptoms pass out of the picture and hepatic or renal symptoms predominate, either almost purely hepatic, hepatorenal, or purely renal in type.

Carbon tetrachloride is not readily decomposed in the system, and, as far as we know, it acts integrally when inhaled or ingested. It may also be absorbed through burned skin areas or open wounds, although the most usual cases of industrial carbon tetrachloride poisoning are due to fume inhalation. It has been used to a considerable degree as a vermifuge, as have trichlorethylene and tetrachlorethylene, but time does not permit of detailed reference to this use. Acute poisonings are usually recognized as such, and the victims are usually promptly removed from further exposure, but chronic poisoning may develop insidiously and severe damage occur before the cause is recognized.

Associated with chronic poisoning we find an increase of blood guanidine, to which some workers have attributed the liver damage; low blood sugar and blood calcium; an increased icteric index and indirect van den Bergh reaction as indication of liver damage; and at times the presence of bilirubin in the urine. An increase in blood lipoids has been demonstrated in exposed animals. McMahon and Weiss²² report the finding of a high percentage of fat in the heart blood of a fatal case with severe liver damage.

Personal susceptibility varies greatly, but as a result of a large number of animal exposures, and physical examinations of over a hundred workers, with 2,000 interferometer measurements of vapor concentrations to which the workers were exposed (measurements being taken through the entire working cycles), we have stated that 100 parts per million is a safe concentration for continuous exposure. Intermittent exposures averaging 100 parts per million are also safe. We be-

lieve that 1,000 parts per million is a safe peak concentration for not over one-half hour, with the average for the rest of the day not over the 100 parts per million level.

A saturation of 100 parts per million of carbon tetrachloride is noticed, by most people coming into the atmosphere from one free of carbon tetrachloride, as a barely perceptible odor. If the average nose recognizes more than a faint odor on entering a workroom, an increase in ventilation or a more complete inclosure of the process is called for.

Exposures to very high concentration of carbon tetrachloride may result in almost immediate unconsciousness and death, but such fatalities may be delayed, with death occurring up to twelve days after exposure. In these cases severe complaints may not begin for one or two days. Then the worker may complain of headache and nausea, with temperature rise. Pulmonary edema may develop, followed by pneumonia, as in a fatal case I saw, or tonic or clonic convulsions may appear, followed by unconsciousness. Later the patient becomes cyanosed, dyspneic, and covered with cold perspiration, and develops a weak and rapid pulse. Urine may be scanty, with high albumin content and presence of white and red cells, and the patient may die in uremic state. Brief exposures to high concentrations may result in temporary narcosis with recovery without evidence of hepatic or renal injury.

The most comprehensive clinical studies on carbon tetrachloride poisoning appear in a doctoral dissertation by André Domart²³ published in Paris in 1938. In addition to the fatalities from acute effects already referred to, which are not common, he recognizes hepatic, hepatorenal, and predominantly renal types, though in all cases there is more or less damage to both liver and kidneys.

In our experience and observation, patients surviving acute attacks usually progress to complete recovery. Hepatic cases present the picture of fatty degeneration of the liver which, if exposure continues, progresses to a picture of toxic hepatic cirrhosis. These cases start with nausea, vomiting, dizziness, gastrointestinal disturbance, jaundice, and hepatic tenderness with liver enlargement. Even with the clinical picture of hepatic cirrhosis, proper treatment, if continued, may lead to complete clinical recovery. In contrast to the effects of poisonings by many other industrial solvents, patients who recover from chronic carbon tetrachloride poisoning are often able to return to work with a definitely

ill effects result from a continued or intermittent condition of low-grade narcosis, of varying degrees of intensity, and, if so, precisely what these effects are and how they may be detected at an early stage, before clear-cut disease entities have made their appearance.

Our medical staff is wrestling with this problem at the present time. We are attempting to find a useful measuring stick for narcosis which would make possible the accumulation of just such data. While the approach to the problem is a theoretical one, its implications are highly practical for the control and prevention of occupational diseases. Perhaps some of the members of this audience will be sufficiently interested to work on it.

That a combination of toxic substances is apt to be more toxic than is the sum of its toxic components is a general principle which we hear reiterated from time to time. It apparently has a substantial basis in experience, both in the experimental toxicological laboratory and in industry. For this reason I should like to tell you briefly about an interesting case which came to our attention, where there was exposure to a combination of several of the chlorinated hydrocarbons we have been discussing.

This man, 26 years of age, was engaged in applying a paint remover in reconditioning elevators in buildings. Because of the nature of the work, no ventilation was provided. The paint remover contained carbon tetrachloride, chloroform, and a considerable number of the higher chlorinations of ethane, propane, butane, and pentane—the exact chemical components being unknown even to the producers because of the overlapping of boiling points.

The man worked with the paint remover for about a year and lost some 40 pounds in weight during this period. We have no knowledge of other elements in the clinical picture during this time because we learned of the case only after his death. About five days before admission to the hospital, however, he complained of severe abdominal pain with vomiting, and presented a general picture of surgical abdomen.

Examination of his blood in the hospital prior to operation showed that he had a white cell

count somewhat below 3,000 and a red cell count slightly above 3,000,000. There was a marked increase in bleeding and clotting time and platelets were greatly reduced. A laparotomy revealed necrotic ulcerations of the colon. The bleeding was such that nothing could be done. At autopsy he was found to have an aplastic anemia with a granulocytopenia, generalized purpura, toxic nephrosis and hepatosis, and necrotic ulcerations of the colon.

The combined injury to the hemopoietic system, liver, and kidneys presented by this case is of the greatest interest in view of the nature of the exposure. Even the necrotic ulcerations are of special interest because they are a frequent accompaniment of agranulocytosis, being found more often, however, in the mouth and throat than elsewhere. However that may be, and regardless of whether, in this particular case, the disease actually was caused by the paint remover, the clinical picture is so suggestive of what might be expected to occur under the circumstances that it is very impressive indeed. In fact, one would almost feel the need to invent such a case for teaching purposes if it did not exist.

Before closing, I should like to say one word about a fourth case we are about to report of poisoning from exposure to one of the chlorinated naphthalenes. It relates to an interesting question of therapy in these cases. As you know, it is customary to treat cases of toxic hepatitis with a high carbohydrate diet. The girl in question had been in the hospital for five weeks, running a steadily downhill course on this accepted therapy. Then one of the doctors suggested that because her serum protein continued to be very low, and she was excreting large amounts of albumin in her urine, an attempt be made to treat her with a high protein diet as one would treat the ordinary case of nephrosis. With the institution of this regimen the patient steadily improved and ultimately recovered. This interested us very much, because it is believed that a person suffering from a toxic hepatitis associated with a blood dyscrasia is apt to have a low serum protein.

LONGEVITY OF PHYSICIANS

Physicians always advise their patients how to live longer and better; they themselves often die prematurely of preventable or at least postponable causes. The prevalence of deaths from heart disease, particularly coronary disease, among relatively young physicians has in recent years increased sharply. Coronary disease has come to be known among physicians as "doctors' disease." Doctors favor health supervision without waiting for illness to appear. In 1922, the National Health Council and the American Medical Association declared themselves in favor of periodic health examinations of apparently healthy persons. The American Medical Association has published a manual¹ and a blank² in

the hope of stimulating medical interest in periodic health examinations, and several pamphlets³ intended to interpret the idea to the layman. Nevertheless, except for insurance-company and industrial periodic examinations, the idea has not become popular. . . .—J.A.M.A.

Discussion

Dr. May R. Mayers, *New York City*—Dr. Smyth has presented such a comprehensive discussion of the subject that I am afraid there is little I can add. However, we have had some first-hand experience with the halogenated hydrocarbons in New York State, and I may say a few words about some of the medical questions which have especially interested us recently and some of the investigative procedures they have suggested to us.

As Dr. Smyth has properly emphasized, this whole group of substances, even in relatively low concentrations, tend to have a somewhat narcotic effect upon persons exposed. Low-grade narcosis, such as one sees in workers exposed to trichlorethylene, for example, tends to make them drowsy, irritable, restless; and they are apt to complain of vague subjective gastrointestinal disturbances which are not easy to verify on physical examination. It has been our experience that, with everyone psychiatri-

cally minded nowadays, there is a tendency to look upon these people as cases presenting personality changes, and to refer them for study to a near-by psychiatric clinic, without stopping to investigate the occupational history. In fact, we have had ample experience to indicate that grave mental and neurologic changes, frequently indistinguishable clinically from true psychoneuroses, or even psychoses, may result from exposure to solvents of various sorts. I wish, therefore, to warn against a diagnosis of mental disease without careful investigation first of the occupational exposure of the patient.

Before leaving trichlorethylene, I should like to refer to an explosion which recently occurred during use of this supposedly nonexplosive substance, believed to have been due to using it in a degreasing tank located in close proximity to some welding operations, where unusually high temperatures were being generated. Particularly now, when welding operations are rapidly multiplying in industry, the possibility of such a contingency should at all times be borne in mind.

Carbon tetrachloride is the substance which continues to give us more compensation claims in New York State than do any of the other chlorinated hydrocarbons. This may be due to the fact that practicing physicians are, in general, unfamiliar with the toxicological properties of the other members of this group, but do more often than not recognize and correctly diagnose cases of liver damage due to carbon tetrachloride. We thus have no way, unfortunately, of appraising with any degree of accuracy the relative incidence of occupational diseases caused by the individual substances under consideration.

The question of maximum permissible limits always presents a fertile field for discussion. In the case of carbon tetrachloride, as you know, the accepted limit is 100 parts per million. You will be interested, therefore, in a recent experience we had in a plant using this substance to clean motion picture films. Despite the fact that the concentrations never exceeded 100 parts per million, and were usually 80 parts per million, all of the boys working in this atmosphere complained bitterly of drowsiness, fatigue, and in some cases of loss of appetite, nausea, and even vomiting. When, at our suggestion, the leaks in the drying room were repaired and ventilation improved so that the concentrations of the carbon tetrachloride were still further reduced, all symptoms disappeared. We are inclined, therefore, to drop the permissible limit for this substance below 100 parts per million.

Low-grade narcosis is a most interesting medical phenomenon about which we know far less than we should. We should like, for example, to be able to make up our minds as to precisely what degree of narcosis must be present before we say a person is "sick" or "disabled." We should also like to have sufficient data to enable us to determine more accurately than has been possible to date whether any permanent

ill effects result from a continued or intermittent condition of low-grade narcosis, of varying degrees of intensity, and, if so, precisely what these effects are and how they may be detected at an early stage, before clear-cut disease entities have made their appearance.

Our medical staff is wrestling with this problem at the present time. We are attempting to find a useful measuring stick for narcosis which would make possible the accumulation of just such data. While the approach to the problem is a theoretical one, its implications are highly practical for the control and prevention of occupational diseases. Perhaps some of the members of this audience will be sufficiently interested to work on it.

That a combination of toxic substances is apt to be more toxic than is the sum of its toxic components is a general principle which we hear reiterated from time to time. It apparently has a substantial basis in experience, both in the experimental toxicological laboratory and in industry. For this reason I should like to tell you briefly about an interesting case which came to our attention, where there was exposure to a combination of several of the chlorinated hydrocarbons we have been discussing.

This man, 26 years of age, was engaged in applying a paint remover in reconditioning elevators in buildings. Because of the nature of the work, no ventilation was provided. THE USE OF BOVINE ANTITOXIN FOR THE PROPHYLAXIS OF TETANUS

JEROME GLASER, M.D., Rochester, New York

APPROXIMATELY 50 per cent of all deaths from tetanus in the United States occur in children under 15 years of age, so that the prophylaxis of tetanus is at least as important to the pediatrician as to any other medical specialist. Toxoid would appear to be an ideal agent for the prophylaxis of tetanus but this procedure is not yet in general use. Because of my particular interest in allergy as related to pediatrics, the majority of my patients are either allergic themselves or members of families with major allergic diseases. My experience with horse serum tetanus antitoxin in treatment of these patients was consistently disagreeable. In 1933 it was brought to my attention that a bovine tetanus antitoxin was being made in this country, and since that time I have used no other preparation.*

Bovine antitoxin for the prophylaxis and treatment of tetanus and diphtheria was introduced by Kraus^{1,2,3,4} and his associates in Buenos Aires about 1921. They did this because a large experience in the therapeutics of typhus and human anthrax had shown marked freedom from reactions following the use of normal bovine serum. They demonstrated that bovine tetanus and diphtheria antitoxic serums were just as effective as similar equine preparations, while their use was to a large extent free from the disagreeable sequelae of horse serum.

Bovine tetanus antitoxin was introduced into this country in 1929. Since the original work of Kraus there has been very little pub-

lished on this subject, though in 1936 Glaser and Landau,⁵ in discussing the prophylaxis of allergic disease, advised the use of bovine tetanus antitoxin with particular reference to the avoidance of serum reactions and of sensitization to horse serum.

My experience with bovine tetanus antitoxin comprises 38 cases. The patients ranged in age from 1½ to 18 years, with an average age of 7. Although I have used the preparation in adult cases, none are included in this series; but it may be said that adults tolerate the serum fully as well as children. Time permits the reporting in detail of only two of the most interesting cases.

Case Reports

Case 1.—This boy was admitted to the emergency treatment room of the Genesee Hospital for treatment of numerous brush burns and scratches received in an automobile accident in which he had been dragged for a distance along the road. The attending physician advised tetanus antitoxin and the boy was given a routine intradermal test with horse serum diluted 1:10. Immediately following this he became cyanotic and unconscious, made convulsive movements, and appeared about to expire from immediate anaphylactic shock. However, he revived upon the subcutaneous injection of epinephrinehydrochloride, 1:1,000 solution, and with artificial respiration. He was kept in the hospital overnight and referred to the Allergy Clinic, where he appeared a few days later. At this time he was tested with 1:10 bovine serum intradermally, with negative results (following a negative scratch test to the same substance) and 1,500 units of bovine tetanus antitoxin were given in divided doses over a period of one hour, with no difficulty whatsoever. The boy was detained at the hospital for several hours before being sent home. Two weeks later he reappeared at the clinic and reported no symptoms which might be interpreted as a serum reaction. This was the only case which was not treated in private practice, and coming early in the series impressed upon all observers the value of bovine tetanus antitoxin.

Case 2.—This boy had had asthma since the age of 2. At the age of 8 he came under treatment, which was discontinued against advice at the age of 11. He had been completely free from attacks during the last year of treatment, except for two occasions, when adequate and easily avoidable exposure caused mild attacks. On

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

From the Department of Pediatrics, University of Rochester School of Medicine and Dentistry, and the Pediatric Services, Strong Memorial, Rochester Municipal, and Genesee hospitals, Rochester.

*All of the bovine tetanus antitoxin used by the author was purchased on the open market and was prepared by the Mulford Biological Laboratories, Sharp and Dohme Company, Philadelphia, Pennsylvania. As far as the author can determine, no other bovine tetanus antitoxin is prepared in the United States or Canada. Until the lyophil preparation (Lyovac), which has a five-year dating, became available in 1939, the conventional liquid serum was used. The lyophilized tetanus antitoxin (bovine) is available in 1,500-unit and 10,000-unit doses. Each package contains a 1 cc. ampule of normal bovine serum (diluted 1:10) as test and hyposensitizing material. If the preparation becomes outdated before use, it will be exchanged by the company without charge.

July 4, 1940, while he was visiting in a neighboring town, a firecracker exploded in his hands, severely lacerating the fingers and palms. The wounds were treated by a local physician, who also attempted to administer horse serum antitoxin, despite a strongly positive skin test. The patient was given two injections, of an unknown but small amount, at half-hour intervals. Half an hour after the second injection he experienced itching about the eyes, broke out with generalized urticarial wheals, and complained of abdominal pain and difficulty in breathing. The symptoms were relieved by the administration of epinephrine hydrochloride and the boy was brought back to Rochester.

The following day he was somewhat edematous and asthmatic and suffered from nausea and vomiting. A day later he was given a scratch test to bovine serum, and this was followed by a negative intradermal test to the same substance. Thereupon 1,500 units of bovine tetanus antitoxin were given in divided doses without difficulty. Two days later the patient experienced a severe delayed reaction to the previous injections of horse serum. This was evident because of severe local reactions at the site of the previous skin test to horse serum and at the two sites where the small amounts of horse serum had been injected. There was no reaction whatsoever at the sites of testing and injection of the bovine serum. He was uncomfortable for a number of days, and when the reaction cleared up about six days after the original injury, he was again given 1,500 units of bovine tetanus antitoxin, with no disturbing sequelae then or any time later.

In three instances, because of subsequent injuries occurring from weeks to months after the first injection of bovine tetanus antitoxin, it was necessary to repeat the injection. Disagreeable sequelae of any kind were not encountered.

The personal history of the patients was known in all but 1 case. Among the remaining 37 children there was a personal incidence of allergic disease to the extent of approximately 49 per cent. Certainly a series of this type should be suitable for testing the safety of the parenteral injection of a foreign protein.

Of the 38 patients in the series 15 cases (39.5 per cent) experienced some reaction to the bovine antitoxin, varying from a questionable itching at the site of injection of the serum to two instances of moderately severe serum sickness. The incidence of serum reaction was equally divided between the patients with a personal history of allergy and those who had no personal history of allergy. The usual reaction was the appearance of a few urticarial wheals lasting from a few minutes to a few hours. In no case in this series was there an immediate anaphylactic reaction to the bovine

tetanus antitoxin, and in only one instance was the serum sickness so severe that the parents desired the child to be seen by the physician.

The only published report on a series of reactions following the prophylactic injection of horse serum for tetanus in amounts comparable to those of bovine serum employed in my series is that of Lyall and Murdick.⁶ These authors published the results in a series of 1,000 cases of all ages. Of these, 15.2 per cent developed generalized reactions (of which only 0.2 per cent were alarming) as compared with two generalized reactions (neither of which was immediate nor alarming), or 5.1 per cent, in my series. The protein content of the horse serum averaged 9 per cent, that of the bovine serum 7 per cent. My series, however, is so small that this comparison with the series of Lyall and Murdick possesses only academic interest.

It is attractive to speculate that most individuals are relatively immune to bovine serum because the proteins of the serum are probably much the same chemically and immunologically as those of beef and milk, and that through the ages as man has used these substances for food he has built up an adequate mechanism for detoxifying these proteins. However, we know that this is not true because cow-milk sensitivity is the most common form of allergy encountered in infancy. The explanation doubtless lies in the observation of Wells and Osborne⁷ that animals fed with milk are not good subjects upon which to try anaphylaxis experiments with milk, as they may have acquired more or less of an immunity. Incidentally, this observation probably explains the rarity of acute anaphylaxis in man following the use of milk protein for nonspecific foreign protein therapy. I have had no experience as to what might happen if a milk- or beef-sensitive individual were given bovine serum.

Conclusions

1. Bovine tetanus antitoxin has been used with safety in selected cases known to give severe anaphylactic reactions to horse serum.

2. The only indication for the use of equine tetanus antitoxin is in those cases where the individual is known to be, or can be demonstrated to be, sensitive to the bovine but not to the equine preparation.

3. Individuals undergoing study for allergy should be tested routinely with equine and bovine serum. This should be done by the scratch method only, to avoid as far as

possible sensitizing the individual to the serum. If the individual is sensitive to both serums he should be immunized by means of tetanus toxoid.

"NIACIN" ADOPTED AS SYNONYM FOR NICOTINIC ACID

A synonym for nicotinic acid, the antipellagra factor in vitamin B₃, has been selected by a committee named for that purpose by the Food and Nutrition Board of the National Research Council, it is reported in the *J.A.M.A.* for March 7, 1942.

"Niacin" has been selected for nicotinic acid and "niacin amide" for nicotinic acid amide. The Council on Foods and Nutrition of the American Medical Association announces that it has approved these synonyms for preparations that come within its scope. Niacin is pronounced with a long *i* and a soft *c* (ni'a-sin).

Discussing the selection of these terms, an editorial in the same issue of the *Journal* says: "The choice of 'niacin' appears to be a happy one. The name is not therapeutically [from a treatment point of view] suggestive. Although 'niacin' is not altogether suitable from the purely chemical point of view, chemists and other scientists generally will continue to use the older terms, which to the initiated are unobjectionable. Whether the new names will overcome resistance to the greater use of enriched flour and enriched bread remains to be seen. They deserve to meet general approval."

Discussing the reasons for the selection of these synonyms, the editorial says:

"A poor name is a handicap to the promotion of a meritorious product. The name 'nicotinic acid' for the vitamin so important in the prevention of pellagra has been doubly unfortunate. To the general public the word 'nicotinic' implies

too strongly the relationship of this vitamin to nicotine, the chief alkaloid of tobacco often used as an insecticide. The term 'acid' denotes a corrosive substance such as the liquid used in automobile storage batteries. The vitamin called 'nicotinic acid' was first produced in the laboratory in 1867 by the oxidation of nicotine with potassium chromate and sulfuric acid. Later the compound was named nicotinic acid because it had been made from nicotine and it had the ability to form salts. As a laboratory curiosity, which it remained for over seventy years, nicotinic acid was adequately named. From the point of view of those interested in furthering the distribution of foods enriched with this dietary essential, the name has proved unsuitable.

"Following the announcement of proposed regulations for enriched bread by the Food and Drug Administration, a well-known trade publication announced the event with the heading, 'Tobacco in Your Bread,' because nicotinic acid happened to be one of the dietary essentials which is added to the product. Although nicotinic acid was first produced from nicotine, and even now a small proportion of this substance is being produced commercially in this manner, the implication that tobacco is contained in enriched bread is far from true. Most of the nicotinic acid of commerce is produced by the oxidation of beta-methylpyridine, a coal tar derivative. Although nicotine is a toxic substance, nicotinic acid is a vitamin essential to life."

VISITING PROFESSORSHIP PLAN

The Long Island College of Medicine is introducing an old idea in a new form through a series of visiting professorships, financed by a grant from the Commonwealth Fund of \$4,500 a year for three years. Proceeding on the idea that all departmental heads would like to strengthen some phases of their teaching program, the college is inviting scholars from other institutions for short periods to make specific contributions to the curriculum.

Dr. Thomas Addis, Stanford University School of Medicine, joined the Long Island faculty March 16, as the initial visitor under the new plan. He will remain for six weeks as the guest of Dr. Tasker Howard, professor of medicine. Dr. Wilson G. Smillie and members of his staff at Cornell University Medical College have ac-

cepted the invitation of Dr. Wade W. Oliver, professor of bacteriology, to give the spring trimester course in parasitology and tropical medicine to the second- and third-year classes.

"Because of war conditions with their drain upon our faculties, there will be need for great flexibility in the efficient use of available teaching resources. Though war conditions may make the application of the visiting professorship plan more difficult, the opportunity for selective strengthening of a medical faculty is especially inviting at a time when budgets lag behind the rapidly growing demands made upon them. Not all of the benefits should accrue to the host institution, for, if the plan justifies itself, it is to be hoped that it may be extended to other schools as well," writes the L. I. college.

RELATION OF A SPECIALIST TO THE GENERAL HOSPITAL AND ITS PERSONNEL

FRANK M. SULZMAN, M.D., Troy, New York

IF WE give thought to this subject, several factors will focus our attention, and in order to analyze the conditions properly, let us first divide our hospitals into three classes:

1. The general hospital in which a separate and distinct portion of building and personnel are turned over to the specialist, as for the work of the eye, ear, nose, and throat men: while part of a general hospital, this is a distinct unit in itself;

2. The general hospital that has on its staff men associated with our specialty, who are given ward and room privileges for their patients, and that also has rooms in the operating suite suitable for this particular work;

3. General hospitals that call specialists as consultants and have no attending staff, but depend on men from other places for this work.

As the first classification represents an almost ideal condition, let us stop for a time and contrast the situation of a man working in this type of hospital and that of men related to the two latter types.

The first man has the benefit of three important divisions, laboratory, x-ray, and nursing trained for special work, and, with a well-trained house staff sympathetic to the work, an apparently ideal setup is encountered. Unfortunately this is not the ideal condition that many of us work in.

Contrast this with the situation of a man who does clinic work one or two days a week. His patients are placed in general wards together with seriously injured or ill patients. This does not furnish the calm and reasonably quiet surroundings that a patient recovering from a major eye or ear operation requires. For those of us who are connected with so-called general hospitals, it has, I am sure, been increasingly difficult to overcome certain factors with which our colleagues who work in hospitals entirely devoted to our specialty are not confronted.

Let us consider the problems of staff and staff conferences, interns, nursing, and laboratory and working conditions. How can we increase interest in our work at the hospital conferences or county medical society meetings? It is common knowledge that to read a

paper dealing with one of the many problems in which we are interested is a waste of time and little appreciated by a mixed group, by whom our work plainly is not well understood. Papers dealing with subjects combining their work and ours seem to have value and interest for them, but papers on operative work, like cataract, strabismus, mastoid, etc., have little interest for them.

What can we do to make the position of the specialist less subject to criticism and opposition? Do certificates of the different boards help to solve this problem? Shall we endeavor to stop the widespread specialty work done by many general men?

Staff Appointment

In regard to specialists, what standards should be required as qualification for staff appointments? Certain questions arise that need clarifying by men classifying themselves as specialists. For instance: how often are we asked to recommend a man whom we know to have a meager training and such training, in many cases, of doubtful character and subnormal standing? If you refuse to sanction such a man, you are accused of being personal and afraid of him as a competitor. These unpleasant conditions are not rare, and I feel that some definite standard should be set before a man is eligible for a staff appointment.

A few personal thoughts on this may be of value. Should not a definite assistantship and internship, or residency in a well-recognized special hospital, or in a general hospital having a properly trained special department, be necessary? Regarding certification by one of the boards, we know that this is a debatable point, but the time is fast approaching when it will be necessary to settle this question. It will prevent much of the present handling by general men of tonsil and other operative work that properly belongs to a special department. Insistence that this work be done by men properly qualified will help to solve the difficulty and remove a source of friction and ill feeling among departments.

Each department should have a chief who by training and experience merits the confidence of his colleagues and who holds certi-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, May 1, 1941.

fication by one or more of the recognized American boards, and an active attending staff for the ward and clinic work. The latter should be made of mutual interest by weekly conferences on the material for operation and treatment.

House Staff

One member of its personnel should have a definite service and duties in a specialty department, to become familiar with the active cases. In emergency and night work he could do valuable service for both the patient and the attending men. Our work being somewhat limited, we usually have to share the time of the intern on our service with other special services. In many instances, one seldom sees a house man except when operating. It is well nigh impossible to train your house staff under such circumstances except in operative work. Valuable clinical experience, ward rounds, etc., are all mostly forgotten or omitted.

Nursing

A training school where adequate teaching is given, so that the procedure of treatment, preoperative, operative, and postoperative, will be properly carried out. It is the experience of many that graduate nurses from distant points present a difficult problem in nursing care, when their training has been of a quality not in conformity with modern methods and treatments.

Laboratory is another subject that may well be considered in a mixed meeting, as problems of mutual interest are bound to come up.

Since the specialist sees a limited number of cases, his x-ray and laboratory work are in many instances not taken with the seriousness or wholehearted cooperation needed to solve some of the difficult problems that too often occur. Unless the laboratory is specially trained, the cultures and smears will not get the detailed examination so necessary to arrive at a proper diagnosis.

One of the main difficulties in our x-ray work—with this many will agree—is proper position for mastoid and sinus pictures. It has been our experience to have sinus plates reported negative, while clinically and by operation we have found an antrum filled with pus—this by a man who really tries to furnish good pictures, but fails to compare his technique with that of colleagues in the same work and so keep abreast with new methods, so helpful in solving these difficult diagnostic problems.

In our monthly clinical meetings with the general staff, someone representing our specialty should be on the program committee, as we can thus arrange many of the meetings so that the program will be of mutual interest. For example, in relation to anesthesia, it will be found very valuable and of great general interest to invite some of the well-known men who specialize in this field to address us, so that new and better ways of using our older anesthetics will be developed, and interest in the newer ones stimulated.

X-ray

Many of our local men might talk on this subject, but it is well to have some new personality with different connections appear once or twice a year. It will add much practical information in an important field.

Diet

While this may seem foreign to my subject, a knowledge of present-day advances in this extensive field is highly desirable and useful. The marked advance in the knowledge of feeding infants is only a forerunner of what may be expected in other fields.

Allergy

This wide field, still in its infancy, can be a most profitable source of practical information for all.

General Medicine

I believe that a lot of valuable information is lost by not having the proper consultations between the different departments and the specialist. For instance, all diabetic, nephritic, and arteriosclerosis cases, and the so-called cardiorenal group, should be seen by the attending specialist and fundus changes noted at frequent intervals. This would give valuable data to have later for information. Regarding treatment and other factors influencing these cases, it would also be a source of excellent instruction for house staff members to use the ophthalmoscope under proper guidance.

General Surgery—Head Injuries

How can we best get our colleagues to refer head injuries for examination, even if no wound is observed near the organs of special sense? If consultations in all head injury cases were compulsory, we would be in a better position to make important observations now lost sight of in many cases. Changes in the ear, if any, could be included in the

useful information that would be obtained after these examinations, and help clear up some of the disputed points that arise later. I have in mind several cases that were not examined for fundus changes or otherwise, that left the hospital and came back later with severe intracranial symptoms that might have been anticipated had a previous examination of the fundus, etc., been made.

Pediatrics

Further information on the disputed points of ear conditions associated with gastrointestinal symptoms could be worked out. All strabismus cases should be referred by the pediatrician for eye examination. Many, if seen early, could be advised concerning treatment, even though they might have come into the hospital with conditions not associated with the eye. The same applies to routine nose and throat examinations. These cases should be examined by the attending staff in specialty departments, as laryngoscopy, and bronchoscopy in chest cases.

An arrangement such as we have outlined above will give opportunity for better service and allow us properly to arrange our time in the hospitals and elsewhere. It would also tend to safeguard against the pitfalls we now often encounter, in being asked to see a case that has been in the hospital several days and should have been referred for our examination after the admission examination. These examinations often conflict with prior engagements and do not allow us time to go into details which may be vitally important.

On the other hand many attending men in general hospitals give several hours weekly to attendance in clinics held on one or more days a week. At the end of the year this amounts to many hours of hard, thankless labor. It has become increasingly apparent that the poor, who we all agree should be taken care of, and for whom we all willingly and wholeheartedly give the best we have, are being crowded out of the average clinic. Nowadays we find in the free clinic many who could well afford to pay at least a moderate fee, but who for one reason or another seek the benefit of free services. Our eye clinics are largely made up now of refractive work that requires hours of labor to care for properly.

It is exasperating to spend one's time doing this work and find patients coming back in a week or two with expensive frames and fittings. Of course these may be purchased on credit, but more than likely are paid for. It is

disconcerting to see this, and it is not an infrequent occurrence.

The number of tonsil and adenoid cases reporting to the clinics for operation is steadily increasing. It is unpleasant to meet one of your colleagues after you have been working several hours in a clinic or operating room on service work, and be told that the individual you have just operated on as a charity case has this man for a regular family physician, and that he is paid. Cooperation should be obtained to prevent this violation of the principles of fair play, which in the end will work no good for either side. For only a little later the general man or surgeon will find a similar condition in regard to some of the cases upon which he operates.

Some years ago we tried out a system of cards, which were given to the patients at their first visit to the clinic, to hand to their family doctors to fill out. The card bore this simple question: "Do you think the patient eligible for free clinic work?" The family physician, of all parties concerned, should know the person's circumstances; yet, strange as it may seem, we received very little cooperation, and the expense of the cards, printing, etc., was considered too much for our county society to continue to bear. Yet it is of vital importance in overcoming any such nuisance that all should bear a fair share in eliminating the abuses.

The third major problem to confront is us the child or adult with impaired hearing. One is given a report that the child has impaired hearing, by a test conducted at his school. The average school doctor or nurse is not a specialist. These tests are made and a report is sent, and we are called upon to verify it.

This is a real job, in most cases requiring time and thought. It involves great social and economic responsibility and much depends on one's judgment. An increasing number of these cases present themselves each year, and, with the refractive work, take a major portion of one's clinic time. How far are we justified in going further with this work without some financial recompense, as it adds neither to one's experience or even interest but is just plain hard work? It is time that some more equitable distribution of public moneys be made, on the basis of compensation for work really done. I say this not in behalf of socialized medicine—far from it. But funds are allotted for nearly everything else, and it is manifestly unfair to ask that such work be continued longer on a charitable basis.

Conclusion

1. An opportunity exists to avail ourselves of material that may reveal important data on clinical subjects which are now seldom systematically examined by the specialist. These data could be made a research study of value not only to the specialist but to the different departments in a hospital.

2. Closer cooperation and active participation at clinical conferences and county society meetings will give evidence of our ability to meet present-day problems in our specialty.

3. Let us all endeavor to have some standard established for qualifying a man as a specialist, and thus prevent some of the mediocre work now permitted. By this we shall render a real service to the patient and place our department on a high standard. An appointment in a hospital having such standards would be considered an advancement and an honor.

4. Certain economic factors require study for correction of abuses now apparent to all doing clinical work. We must stop fault-finding as our only defense, develop a plan that can be made workable, revise it as its weaknesses become apparent—but in Heaven's name let us do something besides talk. An active public relations committee, in which our specialty will be represented, should be part of all hospital work. The public should be informed in an intelligent way of what is being done by the profession without any recompense. This would counteract the present freely expressed public opinion that we are being paid by public funds, which a large majority of our citizens still believe to be the case.

Discussion

Dr. Albert M. Rooker, *Niagara Falls, New York*—Dr. Sulzman is to be congratulated upon the thoroughness with which he has gone into the subject—so much so that there is little left to discuss. In our city, the hospitals come under his Class 2—i.e., general hospitals with ward and room privileges and separate nose and throat operating rooms. Fortunately, we have no organized clinics or outpatient departments, though we do have cases referred by city welfare physicians for operation.

Prior to October, 1940, neither of our hospitals, each of which has a bed capacity of 200, had a closed staff—i.e., they were open hospitals and anyone could do anything his conscience would permit. But this utopia (for physicians and surgeons) has come to an end, and we are now in the throes of organization—closing the staff. The problems are many and varied, as you can im-

agine when I say that we have eighty-eight physicians in the city and probably eighty of them aspire to be surgeons. Who or what group is to set itself up as a body to say who shall do this and who shall do that?

Everyone took out tonsils and adenoids; shall we specialists say where the line shall be drawn? Well, it was tried, and now some senior major surgeons who, themselves, never take out tonsils, stand by while associates do the operating. You who have always had a closed staff cannot appreciate the difficulties we are encountering.

I agree with Dr. Sulzman that standards should be set, and they are being established by the boards, colleges, etc. But that does not get them on a working basis in a situation such as we have in our city. Then, too, there is the chance for personal animosities to be injected into the situation, as they have been with us, so that we have a real problem, I can assure you, and one that will probably take a long time to solve. It would seem as though the public would become aware of such methods, but they go sublimely on, with confidence in their fellow-man, especially if he is a physician. How can they learn otherwise?

With regard to x-ray, I cannot agree with Dr. Sulzman, since I have had wholehearted cooperation from our roentgenologists. My only complaint would be that they find so much that is not corroborated by clinical findings that one is sometimes unduly influenced in his surgical judgment.

I agree that too many of our nurses have had inadequate training in our specialty, but with the acute shortage of nurses at present (when all those that were graduated from a training school, however ancient, are being called into service), I cannot see how this can be corrected.

There are many other problems far from solution, but I do believe that a paper such as Dr. Sulzman's will start us thinking of these things. It is extremely timely and worth while.

Dr. Wm. J. Hicks, *Middletown, New York*—Dr. Sulzman has raised a very timely question in regard to modern medical practice. The relationship of the specialist to the general hospital and its personnel is one that is now in process of being evolved, because the so-called specialist is a comparatively recent arrival on the medical scene. At some time during the process of stabilization it will be necessary to define the term "specialist." Considerable discussion has already taken place, not only within the profession, but also in lay groups, and even in legislative circles, as to just what a specialist is.

When the Advisory Board for Medical Specialties was organized in 1933-1934, and officially recognized by the American Medical Association at the Milwaukee Meeting of 1933,¹ organized

¹ The Council on Medical Education and Hospitals of the American Medical Association has representation on the Advisory Board for Medical Specialties.

medicine took a long step toward defining the term specialist. This board issued its first directory last year, and it contains the names of over 14,000 specialists certified by the various American boards. This publication is available to professional and lay groups alike. Many of the national societies now require board certification for all candidates, and an increasing number of hospitals require board certification for advancement and full hospital privileges in a given specialty.

The practice of medicine in this country has become a cooperative enterprise, with first of all a definite division of labor into various specialties or fields of practice, and, second, a coordination of these various departments by suitable consultations. Although the coordination still leaves much to be desired, I think most of us will agree that it is improving, particularly in hospital practice. The general hospital today, with its pathologic conferences, tumor clinics, discussion of deaths, and general encouragement of consultations, is rapidly evolving the system of medical practice of the future. It constitutes group practice from the clinical side, if not in a financial sense. If this cooperation is to run smoothly, the division of labor must be definite, and the qualifications and rules for practice in the various departments must be more definite than in times past. It would seem important that just as clinical methods of procedure are brought up to date from time to time, so the method of classifying hospital personnel should be periodically re-examined. The general hospital discharges a moral responsibility as well as a legal one when it classifies its medical personnel, because hospital rating is frequently used as a yardstick.

Dr. Sulzman's paper presents some very familiar problems, and this would seem a proper occasion for an exchange of personal experience and viewpoint.

The Horton Memorial Hospital is a 100-bed Class A hospital in a city of 22,000 and its Eye, Ear, Nose, and Throat division is one of five departments. The head of each department constitutes, with the superintendent and one member of the Board of Directors, a Medical Council which meets at luncheon twice a month to discuss Hospital problems and recommend Hospital policy. Our patients are treated in the general wards, although we have our own operating and clinic rooms. About six years ago our department recommended that major privileges in the Eye, Ear, Nose, and Throat Department be given only to those men who limited their practice to this field and who had passed either the American Board of Ophthalmology or Board of

Otolaryngology examination. This recommendation was accepted by the Medical Council and the Board, and a list of procedures regarded as major surgery was filed with the superintendent. We have therefore what is locally called a closed department, and though a myringotomy classed as minor surgery and may be done by anyone having hospital privileges, a pharyngeal abscess or a tonsil removal is regarded as major otolaryngology and may be done only by one meeting the qualifications above outlined. First assistants at major operations are generally chosen from the department concerned, in order to conform with the general principle that a first assistant at any major operation should be competent to finish that operation in the event of emergency.

There are three members of the Attending Staff in the Eye, Ear, Nose, and Throat division in the Horton Memorial Hospital, and we try to have at least one representative present at the weekly tumor clinic and at the monthly pathologic conference. It is my impression that in our experience the principle of limitation of practice in the various departments has made it possible for us to make demands on each other in a friendly way, of course—that we might not otherwise feel justified in making. We were for instance requested in the Eye, Ear, Nose, and Throat Department, about six years ago, to establish a service in bronchoscopy, and the necessary graduate study was done to make this possible. Likewise, when sinus x-rays became the subject of our own criticism, our full-time and otherwise well-trained radiologist was asked to do some special work in sinus radiology which he did very willingly and with excellent results.

Regarding the relationship of the department to the Resident Staff, we are not a teaching hospital, of course, and do not attempt to teach major surgery, and so the intern does not operate in clinic tonsil cases. We do try to emphasize the importance of being able to diagnose an acute ear or a pathologic fundus. It is my feeling that the teaching of surgery in any specialty should be limited to those institutions equipped to teach first the fundamentals of anatomy and pathology. How else can we ever approach desirable standards?

This limited discussion is offered as an illustration of how we are attempting to solve, in a town of 22,000, some of the problems presented in Dr. Sulzman's paper. We still have far to go, though we believe we are on the right track. We hope to receive valuable suggestions from meetings such as this.

A PEDIATRICIAN LOOKS AT SCHOOL HEALTH EXAMINATIONS

A. CLEMENT SILVERMAN, M.D., Syracuse, New York

ALMOST every time I consider one of the deficiencies of the school health examination, I can think of a corresponding fault or deficiency when the private physician—be he general practitioner or pediatrician—makes a periodic examination. Endeavoring to be fair and objective, I begin to see the need for a consideration of the basic principles and the inherent weaknesses of the system.

In the school health program in New York State, the health examination is now the central element. The law requires an annual examination of every school child, and instructions to this end have been carefully drawn up.¹ It is not unfair to say that until quite recently neither educators nor physicians had formulated a "philosophy" or guiding principles of school health work. The manual of instructions of the New York State Education Department contains everything to be desired, but it still fails to deal with the problem realistically. It speaks of continuous health supervision, of the key position of the teacher, of conferences between the teacher, school nurse, and school physician after observation of the pupils, but it does not consider how all this can be done while retaining the principle of compulsory annual health examination of every pupil, and neither has the education department given impetus or leadership to in-service training of teachers, nurses, physicians, and administrators to effectuate the objectives of the modern school health program.

Method of School Health Examination

The general method of the school examination is largely that of medical diagnosis. Whether we examine a sick child or one who is well, the method is essentially the same; if anything, it may at times be necessary to take more time with a well child than with a sick one. The examination, whether in school or in the doctor's office, makes use of physical methods chiefly. Nor are these to be despised. We need only think of the examination of immigrants in years gone by, when inspection alone was depended upon to sift out

undesirables. It surely is not necessary to make use of all possible diagnostic facilities when a patient presents himself. Neither is it necessary to overemphasize laboratory tests. There is no doubt that undue emphasis has been put on instrumental examination. Patients so often show more willingness to pay for x-rays and other special tests than for the skill necessary to arrive at a diagnosis. It is in line with the disparity between the fee paid the medical man for making a diagnosis of appendicitis and the surgeon who operates for it.

Essential to any examination is, of course, a careful history. Again, in the examination of the healthy child, it may be necessary to take more time to go into his hereditary and family background, his growth and development, his living conditions, his habits and behavior, his activities, food, and sleep. It cannot be denied that upon occasion a careful history will tell us as much or more than certain laboratory tests that we have come to depend upon. Similarly, we often gain more from mere inspection, provided it is backed up by the discernment of experience, than from elaborate but ill-considered examinations or tests.

Nevertheless, it must not be forgotten that there are a great many conditions that a physical examination will fail to reveal. A number of such conditions will occur to us readily: diabetes, epilepsy, kidney conditions, tuberculosis, syphilis, allergic conditions, milder types of endocrine disturbance, or milder forms of mental defect. In recent years, it has become an accepted fact that physical examination methods are inadequate for discovering early pulmonary tuberculosis or accurately determining its extent.

Perhaps the greatest difference between school examinations and those made by the pediatrician is that the latter usually has or obtains a careful background history, and inherently can and does make use of additional methods of investigation, whether by simple or complex laboratory tests, consultation, or further observation. Inherently, he takes the responsibility for following up the child and the parents expect him to assume that responsibility. At the school examination, the parent is rarely present, the child is at best but

¹Read at the Annual Meeting of the New York State Association of School Physicians, Saratoga, New York, June 23, 1941.

From the Department of Pediatrics, College of Medicine, Syracuse University.

partially stripped, and the examination is at best not even potentially complete.

Literature dealing with school medical service has had to give attention to the time devoted to each examination, and comparisons are often made between the time given by the school physician and that given by the private physician, usually to the disparagement of the former. On the other hand, the private practitioner often neglects to test vision and hearing, whereas these are specially dealt with by school physicians, and, though frequently these examinations may be made by nurses or teachers, they constitute part of the school health record. As in many other situations, it is not so much a matter of the time given, though a certain minimum time cannot be lessened, but rather how the time is utilized and to what extent certain elements are dealt with. Those who plead for more time or better examinations fail to appreciate that even with additional time the school examination is bound to be limited in scope. By its very manner, it cannot possibly serve to give a complete appraisal of the child and therefore cannot possibly take the place of good pediatric supervision. Nevertheless, if well performed, the school examination can, within its limitations, serve a very useful purpose when its limited objectives are recognized.

Objectives

The school health examination has a number of purposes and objectives: (1) to serve as a periodic check-up to determine the health status of the individual child; (2) to call attention to defects that might interfere with the child's education; and (3) to serve as a means to health education. These three objectives are obviously interrelated and logically should not be thought of as separate. It should be recalled, however, that school health service had its inception chiefly as a means for controlling communicable diseases. Later, mere inspection of school children gave place to some sort of examination, and still later the search for physical defects was emphasized. More recently, the educational value of the school examination has been stressed.^{2,3,4,5,6,7,8} For the two latter objectives, the importance of the attendance of parents is being strongly emphasized.* Let

* Since this paper was given, there has been published *School Health Services: A Study of the Program Developed by the Health Department in Six Tennessee Counties*, by W. Frank Walker and Caroline R. Randolph, New York, Commonwealth Fund, 1941, in which the role of the presence of parents at school examinations was studied.

us now consider to what extent these objectives are fulfilled.

School Health Examination as Periodic Check-up

There has been a tendency on the part of some to look upon periodic examinations as "the instrument of a hygienic millennium"; many regard it as at least "one of the most powerful instruments of preventive medicine."³ No doubt an occasional individual looks upon a periodic examination almost as a guarantee of good health until the next time. A great many must believe that, should any evidence of disease be discovered, it would certainly be possible to put into action the measures for correction. It is unfortunate that such notions are held too frequently by intelligent people. It is necessary to have an understanding of the limitations of a given procedure. It is perhaps natural enough when disease is encountered in its advanced stages to look back and speculate upon what might have been done toward an earlier diagnosis and earlier treatment; but on the other hand how frequently are we obliged to say that had we known all that we know now we could not have changed things. It is essential to have an appreciation of the human constitution and the hereditary factors involved. There are tendencies in individuals that may be entirely beyond our control. We may be helpful at times in showing people how to manage their lives more intelligently or how better to adjust themselves to their handicaps. Occasionally, too, the periodic health examination may reveal the early features of a remediable condition. It should not be necessary, however, to intimate unwarranted prospects of benefit to make its value apparent.^{9,10}

It is fair to say that the periodic examination tends to measure the health status of the individual at the time of the examination. In the case of a child it gives an appraisal of his condition; another check-up at a subsequent time, after a suitable interval, can give us a measure of his progress or development. I wish I could take the time to speak of Wetzel's work in this connection.¹¹ The periodic examination further provides an opportunity to talk over the habits and behavior of the individual, to investigate symptoms or signs that might have been noted recently or since the last examination, and to elicit knowledge of influences that might be having a deleterious effect.

About one school child in twenty gets ex-

tended to prior to the child's admission to school.

Obviously, no such program can be expected under present conditions from the school health service. The latter can hardly be expected to cover the preschool period. Proper supervision of the school child would still require a tremendously increased personnel with better preparation and a much greater budget than can now be considered. From a practical standpoint, however, a good deal of the job could well be passed on to private practitioners. It should be clear that the purpose here is not to make work for private physicians but rather to give the better type of supervision to those who can afford it and lighten the burden on the school health staff. The objection to the school examination as the central requirement is that it produces a great deal of time-consuming work without resulting benefit. If a considerable number of children could have their periodic examination outside of school, it would save the time of the school staff for those children who perforce must get their medical supervision from the school health service. If the school examinations were not emphasized, it would be possible to develop the idea that the school physician is responsible for general supervision of all school children during the time they are in school. The teacher, school nurse, and school physician could form a group whose job it would be to know as much as possible about each child and to call attention to those requiring special study. There is no reason why a child under the care of a private physician should not be under the observation of this group and their report sent on to the parents for the attention of the child's physician. In the case of a child that does not have his own physician, arrangements could be made for reference to clinics that would carry on the proper supervision with the cooperation of the school health personnel. Much more could then be expected on the educational side of the health service. Parents could be brought together in groups and the importance of various phases of school health pointed out to them and their interest en-

listed. They would know then that the health examination is as good as it can be made, but that it is at best a limited examination which does not necessarily cover all the needs, and that further study and attention may well be required.

Summary

The requirement of an examination of every school child each year has tended to defeat the purpose for which it is ordered. As done at the present time, it does not appear to serve as a periodic examination. It has not taken care sufficiently well of finding and correcting defects, and it appears to fail as an educational procedure. It would appear that the substitution of supervision of the school child as a cooperative effort on the part of the school teacher, nurse, and physician would serve the purpose better. The stimulation of examination and supervision by the child's own physician, in so far as that is feasible, would tend to relieve the burden on the school health personnel.

amined for school by his own physician or pediatrician. The objectives of the periodic examination are not fulfilled in the school health examination; and if time were taken to do so, it would be impossible for the personnel to give such service to each school child annually.

Finding and Correction of Defects

This phase of school health work probably needs the least discussion, because so much has been written on this subject.^{12,13} We might briefly recapitulate, starting out with what appears to be a self-evident truth, that physical defects must tend to handicap the child's schooling. Defects of vision and hearing come first to mind, and then handicaps of nutrition, teeth, tonsils, and the relatively infrequent cardiac trouble. In order of frequency, dental defect ranks first, tonsils second, nutrition third, and visual defect fourth. The objective is not to make a statistical analysis of all deviations from the normal, but to seek out those bodily defects that might have a relation to scholarship. For some of these, there are objective criteria, as for dental, visual, or auditory defects, but for conditions such as those of tonsils or nutrition, the criteria are largely subjective, and the personal equation plays a large part in the evaluation. There is hardly any need for referring to the New York study on tonsils.¹³ It should suffice to recall that in numerous instances a condition is recorded as a defect at one examination and as normal in the next examination. On the one hand, dental defects are so frequent that little purpose is served to repeat the examination; on the other hand, cardiac defects are so uncommon that it would seem uneconomical to continue routine examinations of all children.

Perhaps the most disturbing finding on this score is that whatever relationship there is between bodily perfection and scholarship is at most an indirect one. The anticipated results from correcting physical defects have generally not materialized. Even in so precise a field as visual defect, it has been shown that correction of such defects has not led to progress in reading.¹⁴

There is no intention here to disparage the large amount of good work done in finding and correcting defects. Certain fields of great promise have barely been tilled. The inference that it is desired to call attention to is that certain defects could probably be found almost as readily by screening devices that would consume less time. Furthermore,

greater results could probably be achieved if more attention were given to the children with the more serious defects, instead of spreading the program equally thinly over all school children.

School Health Examination as Educational Procedure

This objective has received more emphasis in recent years, and its purpose is obviously to tie in the school health work with the educational process. It is a safe assumption that almost any human experience is more or less an educational experience. Health teaching, especially with the younger children, is not a matter of didactic instruction, but of the utilization of classroom experiences in furthering health concepts. Obviously, an inspection in school or a physical examination has its educational aspects. It is further emphasized that, with this objective in mind, the parent should be present at the time of the examination, so that both parent and child may participate in the educational experience.

It would seem appropriate to raise a question at this point about the educational value of an inadequate examination. If the present method of school examination leaves much to be desired, if it has at best only a limited scope, might not the educational effect be quite different from what it is desired to be? The contrast between a good pediatric examination and one at school might prove rather "devastating." At the present time, a pernicious by-effect of the school health program is the notion that the school examination suffices to reveal any deviation from the normal, and that when no notice is received it is tantamount to certification of good health. No romantic notions of educational values should be allowed to becloud realities.

Discussion

It might be considered that we have been offering destructive criticism chiefly, that we have been finding fault with the school health procedures, though disclaiming such intention in the beginning. My thesis is that the objectives claimed for school health examinations are not fulfilled. The ideal that is desirable is continuing health supervision of the child from birth and through school, such as a well-trained, conscientious pediatrician might be prepared to give—not alone in the physical field, but also in relation to habits, behavior, and social adjustment. Were such a program feasible, it is very likely that correctable defects would in many instances have been at-

bed between hydrostatic pressure, which tends to force fluid out, and colloid osmotic pressure, which tends to draw fluid in from the tissues. Fluid passes from the arterial side of the capillary bed to the tissue inter-spaces because of a pressure differential favoring filtration by hydrostatic pressure. At the venous end of the capillary bed, hydrostatic pressure has fallen so that now the pressure differential favors the withdrawal of fluid from the tissue interspaces by colloid osmotic pressure. An equal exchange of fluid, first from the capillaries into the interstitial spaces and then back from the tissues into the capillaries, maintains the equilibrium of fluid and prevents both the accumulation of fluid in the tissues and tissue desiccation.

There are many means by which this equilibrium can be upset and edema produced. Any disturbance which produces venous engorgement increases hydrostatic pressure at the venous side of the capillary bed. Thus the differential between colloid osmotic and hydrostatic pressure is changed in a direction which tends to prevent the removal of fluid from the intercellular spaces.

When plasma protein (which accounts for the greater part of osmotic pressure of the plasma) is lost in amounts great enough to produce an appreciable fall in colloid osmotic pressure, insufficient restraint is exerted against the hydrostatic pressure. Thus, more fluid is filtered out of the capillaries at the arterial side and less is drawn back at the venous side of the capillary bed.

Damage to capillary endothelium increases its permeability and not only makes filtration by hydrostatic pressure far easier but also reduces the effective osmotic pressure of the plasma protein and diminishes the amount of fluid drawn back into the capillaries.

All three mechanisms may obtain in the development of cardiac edema. In cardiac failure there is an increase of venous pressure. The relative anoxemia which results from congestive failure may damage capillary endothelium. The malnutrition so often found in chronic heart failure may finally result in a low level of plasma protein.

Theoretically, diuresis may be produced in the presence of edema by mechanisms which are antagonistic to those which produced the edema. Thus, in edema produced by increased venous pressure, reduction of venous pressure will produce diuresis; where low plasma protein is the cause of edema, a transfusion, infusion of plasma or acacia, or proper diet may produce diuresis. The repair of

damaged capillary endothelium as a means of relieving edema remains entirely a theoretical consideration, however, since for this purpose we have no drug, except possibly oxygen, for the capillary damage produced by anoxia.

But the relief of edema may also be accomplished by means other than those which are directly antagonistic to the forces that produced the edema. Fixed base in the body binds water; thus, any drug that will mobilize sodium should also mobilize water and make it available for the kidneys and produce diuresis.

Finally, by a direct action on the kidneys it is theoretically possible to increase the rate of urine formation: (1) by an action on the glomeruli, increasing the amount of glomerular filtrate; (2) by an action on or in the renal tubule, decreasing tubular reabsorption of water.

So we have renal and extrarenal theoretical mechanisms for the relief of edema by the production of diuresis, and there are drugs available for some of those mentioned, except possibly for the repair of damaged endothelium and the increase of the glomerular filtrate.

The drug which statistically produces diuresis most often is probably digitalis. Digitalis produces this effect only in the presence of edema of cardiac origin. By increasing cardiac efficiency, digitalis relieves the mechanical factors which produced the edema. Venous engorgement and hydrostatic pressure at the venous end of the capillary bed are reduced, permitting the colloid osmotic tension to draw the edema fluid from the tissue.

Of the group of so-called "nonthreshold" diuretics, urea is the most important member. These substances are filtered by the glomeruli but reabsorbed only to a small extent or not at all by the tubules. A sufficient concentration of urea in the glomerular filtrate will therefore by its osmotic tension retain fluid and increase the amount of urine eliminated.

Then there is the group of "acid-forming" diuretics, of which ammonium chloride is perhaps the most popular member. As with any ammonium salt, in the body the ammonium is converted into urea, leaving free acid. The acid mobilizes tissue base, making tissue fluid available for elimination by the kidneys.

The xanthine diuretics form an important group of drugs. The mechanism of their action is still being debated. It has been stated by different observers that the xanthine diuretics act by increasing the number of functioning glomeruli, by increasing intra-

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the College and Hospital, students, and visitors. The next report will appear in the July 1 issue and will concern "Treatment of Ocular Syphilis."

The Use of Diuretics

DR. HARRY GOLD: The conference today is on the subject of diuretics.

We might find it more satisfactory, perhaps, to confine our discussions to the use of diuretics in the treatment of heart failure, although if anyone has some burning questions about the use of diuretics in conditions other than heart failure, we might be able to consider those as well.

The diuretics as an effective group of drugs represent a development of very recent years. I have put here a list of agents which I just learned alarmed Dr. Modell, who is going to discuss the pharmacology of the diuretics. They are:

Caffeine	Lithium
Squill	Turpentine
Cantharides	Uva ursi
Buchu	Cubebs

These appear under the heading "Diuretics" in a textbook which was published as late as 1925. It is called *Practical Therapeutics*.

When that was all we knew about diuretics, the patient with heart failure and congestion—let us take a typical case—the patient with luetic heart disease and aortic insufficiency, with edema and ascites, who failed to respond to digitalis, came into the hospital, and after receiving some of these choice remedies, had the fluid removed by means of paracentesis.

This same textbook—and I think it is fairly representative of a practice which prevailed not very long ago—in giving an account of how to treat dropsy of heart failure, states in substance the following: Give a dose of some drastic purgative, such as elaterin, $\frac{1}{20}$ grain by mouth, or compound jalap powder, or compound extract of colocynth. A good deal of emphasis is placed on the importance of purgatives in the treatment of cardiac dropsy. Digitalis is prescribed, and it is advised to have the prescription for powdered digitalis fortified with some powdered squill. The third item mentioned in this outline of treat-

ment is 1 cc. of pituitrin by mouth or by subcutaneous injection two or three times a day. Then it states: "The chief means of relief in cases of ascites is tapping."

That is the picture we had about fifteen or possibly twenty years ago. The patient with congestive heart failure, who no longer responded to digitalis, was doomed.

It is not so now. More than half of the patients with advanced congestive heart failure, in whom digitalis no longer is effective, can be relieved of ascites, hydrothorax, edema, and subjective symptoms in a dramatic fashion by the use of this relatively new group of diuretic agents. Some of them are not new but they have been put to use in much larger doses.

These agents are: (1) organic mercurials, (2) acid-forming diuretics, (3) xanthines, (4) urea, (5) bismuth sodium tartrate.

The xanthines have been in use as diuretics for over fifty years, but they were never very effective until the fear that they might produce dangerous renal irritation proved to be unfounded. The doses were then increased from $1\frac{1}{2}$ grains, once or twice a day, to 5, and even 10 grains, two or three times a day.

How do these newer diuretics act? Something of the pharmacologic background is to be given by Dr. Modell.

DR. WALTER MODELL: If we define as diuretics those substances which increase the rate of urine formation, we include some drugs which act only under the special circumstances found in particular diseases. It is therefore necessary in discussing the pharmacology of diuretics to consider the conditions under which the several diuretics will operate, and, further, to consider the various mechanisms of the production of edema, the specific symptom for which diuretics are used.

Fluid exchange between the capillaries and the interstitial spaces is normally maintained at equilibrium by a balance in the capillary

be kept free of the symptoms and signs of heart failure by the continued use of diuretics, whereas if he goes without them, they soon recur, regardless of other medication.

Finally, I think it should be made clear that treatment with diuretics is effective regardless of the etiology of the heart disease, of the age of the patient, and of the rhythm of the heart.

Unfortunately, in the treatment of ascites due to portal obstruction, the potent mercurial diuretics given intravenously are only occasionally useful. In a patient with massive ascites due to cirrhosis of the liver, it is almost impossible to remove the fluid completely by the use of mercurial diuretics alone. On the other hand, it is sometimes possible, after the ascites has been removed by abdominal paracentesis, to delay the recurrence of ascites and decrease the frequency of paracenteses by administering mercurials twice a week. Used in this fashion, a mercurial diuretic may be of real value in the treatment of portal obstruction.

The third class of patients in whom we use diuretics with good effect are those who suffer from the nephrotic stage of chronic glomerular nephritis with generalized anasarca. Here it should be emphasized that under no circumstances do we use these drugs if there is any evidence of active glomerular nephritis. The type of case in whom we most often use diuretics is one who is incapacitated by massive generalized anasarca resulting from hypoproteinemia, who shows no appreciable number of red blood cells in the urine and who has good renal function. To such a patient, urea or a mercurial may be given, often resulting in effective diuresis and marked reduction of edema. Here, too, the result is by no means so dramatic or so dependable as in the case of heart failure. When we use a mercurial in these patients, we follow them carefully, examining the urine and checking renal function frequently to determine whether the kidneys are being damaged. When we use urea as a diuretic, we check the blood urea nitrogen every two or three days to be sure that it is not being retained in the blood.

We have found that when these precautions are observed, the drugs may be used with safety, and that they are often valuable adjuncts to treatment. There is very good clinical evidence that patients with nephrosis may be given diuretics, including the mercurials, over a long period of time without any deleterious effect on the kidneys.

Urea appears to be a very safe drug to use in most patients, and we seldom see any very

marked accumulation of it in the blood stream as a consequence of using it, even in patients who exhibit some impairment of renal function.

A word about different drugs that we use as diuretics: First of all, there are the organic mercurial drugs such as salyrgan, mercupurin, and salyrgan with theophylline. These are the most potent diuretics we have. They are, as a rule, given intravenously, although intramuscular injections also induce diuresis. When a patient is given one of these drugs for the first time, it is wise to give an initial test dose of 0.5 cc. and then, if there is no untoward effect, to give the full dose of 2 cc. on the following day. We usually administer 2-cc. doses at intervals of two days and continue the injections either until diuresis fails to occur, indicating that the patient is free of edema fluid, or for some reason or other the drug is no longer effective in producing diuresis. Some patients who have received several hundred injections of the drug over a period of years still continue to respond very well and do not manifest any serious toxic effects.

In the twenty-four-hour period following the injection of 2 cc. of mercupurin or salyrgan, usually about 2,000 cc. of urine is voided. Occasionally, one sees patients who pass as much as 7,000 or 8,000 cc. of urine in twenty-four hours after the injection. In general, it appears that the degree of the diuresis is in a measure related to the amount of fluid that has accumulated in the body. A patient with congestive heart failure who has massive pleural effusion, ascites and a swollen liver, and edema of the extremities, may pass 4,000 or 5,000 cc. of urine following the first injection, and then as his symptoms and signs become less and less severe, the diuresis, which follows each injection, becomes progressively less.

One of the disadvantages of the mercurial diuretics is that they are effective only when given parenterally. Consequently, a patient that requires them must see the doctor for every injection. An attempt has been made to get away from this by using the drugs in the form of rectal suppositories. In that form they do provoke diuresis, but the effect is not so striking as when the drug is given parenterally. Moreover, they often produce rectal irritation, causing the patient such pain that he will no longer use them.

Toxic effects from the mercurial diuretics occur rather infrequently and are seldom very severe. A small percentage of patients be-

capsular filtration pressure in the glomeruli, by increasing glomerular filterability, by increasing renal blood flow, by decreasing tubular absorption, and by an extrarenal action that produces plasma dilution. It is definite, however, that the xanthine diuretics do have, to some extent, direct renal action. Diuresis can be induced by the xanthines in isolated kidneys. The importance of the circulatory action of the xanthine group in the mechanism of diuresis is not great, since diuresis appears before the circulatory action is in evidence and persists long after it has disappeared. It is probable that the xanthines exert a direct effect on the tubules to prevent fluid reabsorption.

The mercurial diuretics are about the most potent diuretics we have. Here there is less question about their mode of action. A direct renal action has been demonstrated on isolated kidneys, and *in vivo* by the injection of the diuretic into one renal artery, producing one-sided diuresis.

Both the mercurials and the xanthines increase the amount of chlorides and base excreted. The urinary chloride excreted is increased not only in total amount but also in actual concentration in the urine. Because of this, the production of massive or prolonged diuresis may drive the blood chlorides to low levels. It has been demonstrated that a normal or nearly normal blood chloride level is required for good results from these drugs. In patients who have ceased to respond after repeated administration of these drugs, blood chloride levels have been found to be exceedingly low in many instances. After the chloride levels of the blood were restored to normal, the diuretics again became effective.

In addition, some of the reactions such as nausea, dizziness, and weakness which have followed massive diuresis have been explained by the reduced level of blood chlorides and the loss of base. In some cases these symptoms may be easily relieved by the administration of salt.

The use of combinations of diuretics is very widely practiced. One very common combination is that of an "acid-forming" diuretic and a mercurial. It is an empirical observation that such a combination results in a synergism. In addition, the ammonium chloride supplies chlorides and prevents its depletion in the body.

It is common today to use a mixture of mercurial and xanthine diuretics—mercupurin or salyrgan-theophylline, rather than the

mercurial alone. It is well to remember that these mixtures contain only a small proportion of theophylline (3 to 5 per cent), whereas the amount of the mercurial is considerably greater. This mixture was introduced originally because it was thought that the combination of a xanthine (operating, as was believed, on the glomeruli) and a mercurial (acting on the tubule) would combine the best features of both. That this is what actually happens has not been proved.

DR. GOLD: Dr. Wheeler, will you discuss the clinical aspects of this problem?

DR. CHARLES H. WHEELER: The diuretic drugs are of use in three types of disease, the most important of which is congestive heart failure. They are far less dependable and effective in portal obstruction, with massive ascites such as occurs with cirrhosis of the liver; and the so-called nephrotic stage of chronic glomerular nephritis with generalized anasarca. Unfortunately, diuretics seem to be of little or no value in the treatment of exudates. For example, it is very unusual to see a good result from a diuretic drug in a patient suffering from tuberculous peritonitis with ascites, or in a patient who has a massive pleural effusion resulting from carcinomatosis of the pleura.

Patients who suffer from congestive heart failure are far and away the most favorable subjects for the use of diuretics. Yet it is surprising how many physicians neglect the diuretics. It is not uncommon to see patients with severe congestive heart failure who have been treated in very excellent fashion with digitalis, restriction of fluid, salt, and other measures, but who have been allowed to suffer for weeks and months from symptoms and signs that could have been completely relieved in a very short time by the use of diuretics.

A word should be said about the prophylactic use of diuretics in the treatment of congestive heart failure. They are often very useful in the treatment of patients who have symptoms of heart failure, such as severe dyspnea and orthopnea, or paroxysmal dyspnea, and in whom physical signs, such as rales at the lung bases or edema, have not yet appeared. In such patients treatment with diuretics will often bring about striking relief of symptoms and will sometimes greatly delay the appearance of the full-blown picture of congestive heart failure.

It is unwise, after relieving a patient with severe congestive heart failure of his symptoms and signs by the use of diuretics, to turn him loose and not to continue the use of these substances. Very often such a patient can

be kept free of the symptoms and signs of heart failure by the continued use of diuretics, whereas if he goes without them, they soon recur, regardless of other medication.

Finally, I think it should be made clear that treatment with diuretics is effective regardless of the etiology of the heart disease, of the age of the patient, and of the rhythm of the heart.

Unfortunately, in the treatment of ascites due to portal obstruction, the potent mercurial diuretics given intravenously are only occasionally useful. In a patient with massive ascites due to cirrhosis of the liver, it is almost impossible to remove the fluid completely by the use of mercurial diuretics alone. On the other hand, it is sometimes possible, after the ascites has been removed by abdominal paracentesis, to delay the recurrence of ascites and decrease the frequency of paracenteses by administering mercurials twice a week. Used in this fashion, a mercurial diuretic may be of real value in the treatment of portal obstruction.

The third class of patients in whom we use diuretics with good effect are those who suffer from the nephrotic stage of chronic glomerular nephritis with generalized anasarca. Here it should be emphasized that under no circumstances do we use these drugs if there is any evidence of active glomerular nephritis. The type of case in whom we most often use diuretics is one who is incapacitated by massive generalized anasarca resulting from hypoproteinemia, who shows no appreciable number of red blood cells in the urine and who has good renal function. To such a patient, urea or a mercurial may be given, often resulting in effective diuresis and marked reduction of edema. Here, too, the result is by no means so dramatic or so dependable as in the case of heart failure. When we use a mercurial in these patients, we follow them carefully, examining the urine and checking renal function frequently to determine whether the kidneys are being damaged. When we use urea as a diuretic, we check the blood urea nitrogen every two or three days to be sure that it is not being retained in the blood.

We have found that when these precautions are observed, the drugs may be used with safety, and that they are often valuable adjuncts to treatment. There is very good clinical evidence that patients with nephrosis may be given diuretics, including the mercurials, over a long period of time without any deleterious effect on the kidneys.

Urea appears to be a very safe drug to use in most patients, and we seldom see any very

marked accumulation of it in the blood stream as a consequence of using it, even in patients who exhibit some impairment of renal function.

A word about different drugs that we use as diuretics: First of all, there are the organic mercurial drugs such as salyrgan, mercupurin, and salyrgan with theophylline. These are the most potent diuretics we have. They are, as a rule, given intravenously, although intramuscular injections also induce diuresis. When a patient is given one of these drugs for the first time, it is wise to give an initial test dose of 0.5 cc. and then, if there is no untoward effect, to give the full dose of 2 cc. on the following day. We usually administer 2-cc. doses at intervals of two days and continue the injections either until diuresis fails to occur, indicating that the patient is free of edema fluid, or for some reason or other the drug is no longer effective in producing diuresis. Some patients who have received several hundred injections of the drug over a period of years still continue to respond very well and do not manifest any serious toxic effects.

In the twenty-four-hour period following the injection of 2 cc. of mercupurin or salyrgan, usually about 2,000 cc. of urine is voided. Occasionally, one sees patients who pass as much as 7,000 or 8,000 cc. of urine in twenty-four hours after the injection. In general, it appears that the degree of the diuresis is in a measure related to the amount of fluid that has accumulated in the body. A patient with congestive heart failure who has massive pleural effusion, ascites and a swollen liver, and edema of the extremities, may pass 4,000 or 5,000 cc. of urine following the first injection, and then as his symptoms and signs become less and less severe, the diuresis, which follows each injection, becomes progressively less.

One of the disadvantages of the mercurial diuretics is that they are effective only when given parenterally. Consequently, a patient that requires them must see the doctor for every injection. An attempt has been made to get away from this by using the drugs in the form of rectal suppositories. In that form they do provoke diuresis, but the effect is not so striking as when the drug is given parenterally. Moreover, they often produce rectal irritation, causing the patient such pain that he will no longer use them.

Toxic effects from the mercurial diuretics occur rather infrequently and are seldom very severe. A small percentage of patients be-

come nauseated and vomit after intravenous injections and a few have diarrhea, but rarely are these severe enough to contraindicate the use of the drug. All of the mercurial diuretics produce severe local pain if even small paravenous injections are made. Salyrgan may actually produce a slough under such circumstances, but mercupurin rarely does this. Similarly, salyrgan may produce a thrombosis of the vein into which it is repeatedly injected, but this also seldom occurs with mercupurin. For these reasons, mercupurin is perhaps to be preferred over salyrgan.

In addition to the mercurials, there are available the xanthine diuretics. Those used most commonly are aminophylline, various salts of theobromine, and theocalcin. Physicians vary greatly in their preference for one or another of these substances, although it is difficult to find any evidence that any one is superior. In this hospital, for some reason, we favor theocalcin, probably more on the basis of prejudice than on any real evidence. It is taken in divided doses, usually 1 or 1.5 Gm. four times a day by mouth. These drugs are, however, quite expensive, and a patient of small means often cannot afford them. Another disadvantage is that their effect varies greatly with different patients: some will respond most dramatically and pass 1,000 or 2,000 cc. of urine daily as long as the drug is taken, while others will not have any diuresis at all.

The toxic effects that follow the use of the xanthines are quite inconsequential. Nausea, occasionally with vomiting, is the reaction commonly encountered, and this is seldom severe enough to necessitate stopping the drug.

Finally, a word about urea: Urea, like the xanthines, is taken in divided doses. We usually prescribe 30 cc. of a 50 per cent solution of urea three times a day. It produces the same sort of moderate daily increase in the volume of urine that the xanthines do. Urea is a very good diuretic in the opinion of most people who have used it, and it often succeeds in patients in whom the xanthines have failed. Urea is very cheap, but an important disadvantage is its horrible taste. Some patients cannot take the solution. Attempts are made to disguise the taste, and many people find that grape juice is a particularly effective vehicle. Toxic effects from the administration of urea are unusual, but we have spoken previously of the necessity of following the blood urea nitrogen in order that the occa-

sional occurrence of marked retention of the drug may be avoided.

I agree with Dr. Modell about the use of these diuretics in combination. I think you would find, for example, that most of the patients with congestive heart failure being treated on the wards of this hospital are receiving at the same time daily doses of a xanthine diuretic such as theocalcin, injections of mercupurin every two or three days, and also daily doses of ammonium chloride. The latter is given not only because it has some diuretic effect, but also because in some way it seems to enhance the effect of the mercupurin or the other mercurial diuretics.

DR. GOLD: Well, you have heard a lot of statements about the diuretics. Would you like to take exception to anything that was said? Are there any questions?

DR. MCKEEN CATTELL: Dr. Gold, you have not said anything about the last item in the list of newer diuretics.

DR. WHEELER: Dr. Gold, I should like to ask you a question, if I may. It is stated in the literature that a patient with massive edema who has been digitalized and then receives a dose of a mercurial diuretic, as a result of which he may put out 5,000 or 6,000 cc. of urine, may redigitalize himself by mobilization of digitalis in the edema fluid. As a result he will develop symptoms and signs of digitalis intoxication following diuresis. Personally, I have never seen that nor heard of it in this hospital. I wonder what your views are.

DR. GOLD: There are then two questions: One is about the preparation, bismuth sodium tartrate. This was introduced as a diuretic way back in 1928, and the reports at that time were extremely favorable. A dose of 30 mg. of sodium tartrate of bismuth injected intramuscularly produced an effective diuresis in the patients that were then studied. The effect lasted with diminishing intensity for a period of four or five days. Some years after that another study was made on humans, in which the same general conclusion was reached—that sodium bismuth tartrate is very effective as a diuretic and sometimes causes diuresis when the organic mercurials have ceased to be effective. I understand the hospital in which this was first introduced, Leland Stanford, has used it extensively. Strange as it may seem, no one around here seems to have had any experience with it.

DR. WHEELER: So far as I know we have never used it here.

DR. GOLD: It is something we ought to look

into. It is apparently an effective diuretic.

With respect to digitalis poisoning after massive diuresis, there are a few studies in the literature suggesting that if a patient with marked ascites or hydrothorax and marked edema has been heavily digitalized, a copious diuresis after a mercurial will mobilize the digitalis glucoside which is stored up in this fluid and in that way redigitalize the patient. The evidence leaves something to be desired. I have never seen a case that I could be sure was due to that sort of change. We have all encountered patients who after a very vigorous diuresis develop symptoms—weakness, cramps in the muscles, prostration, and sometimes even nausea and vomiting. There are so many factors that might be responsible for these symptoms. The loss of large quantities of sodium base gives rise to prostration. Also, shift of the acid-base equilibrium toward the base side because of chloride loss may lead to symptoms of alkalosis, with nausea and vomiting.

DR. JANET TRAVELL: I once asked Dr. Eggleston about that and he said he never saw a case of redigitalization following profound diuresis.

DR. WHEELER: I should like to ask Dr. Modell whether there is any pharmacologic evidence indicating which of the xanthines is the most effective diuretic.

DR. MODELL: Of the xanthines, caffeine is least used because of the central stimulation produced by diuretic doses, but I think it is more of an individual and clinical than a pharmacologic problem to discover which of the xanthines would be most effective in a particular case.

DR. WHEELER: There is no evidence that aminophylline is a more effective diuretic than theobromine sodium salicylate?

DR. MODELL: I do not think there is any significant difference.

DR. GOLD: I do not think there is much evidence to justify a choice. It is a problem as old as the problem of dosage.

DR. WHEELER: Then it is impossible to make a rational choice?

DR. MODELL: Theocalcin is stated to produce less nausea.

DR. WHEELER: I think that nausea is just as common following theocalcin as following theobromine. On the other hand, since we use so much more of the theocalcin, it is hard to be sure.

DR. GOLD: That surprises me, for the general statement about theocalcin is that it produces less nausea and vomiting in effective

doses. That was one of the reasons why the manufacturers introduced it. At one time that idea was prevalent about these parts, but apparently that has changed with more experience in its use.

There is not much choice between theophylline and the double salts of theophylline, and theobromine and the double salts of theobromine. Each of these compounds was introduced with some statement regarding lesser irritant action on the gastrointestinal tract. I think Dr. Wheeler said that with the xanthines they are not troubled much by gastrointestinal symptoms.

DR. WHEELER: They occur, but they are not very severe as a rule. If they are severe, we discontinue the drug.

DR. GOLD: Let us hear whether you would agree with this statement: In the endeavor to produce effective diuresis with any of the xanthines, nausea and vomiting or other gastrointestinal symptoms are produced in about 50 or 60 per cent of the cases.

DR. WHEELER: I would say nausea in about 50 per cent of the cases, but not vomiting.

DR. GOLD: It is very difficult to give effective doses without irritating the gastrointestinal tract. These drugs irritate the gastrointestinal tract in animals too, and large doses given to dogs produce ulceration in the stomach and bowel.

DR. MODELL: I should like to mention that the organic mercurials are excreted almost quantitatively in the urine, and as long as there is good diuresis the excretion is fairly complete—80 to 90 per cent in twenty-four hours—but special caution must be taken when the organic mercurials do not produce diuresis. Then there may be retention of mercury in the body, and cumulation with repeated doses.

DR. CATTELL: The same thing applies to other diuretics.

DR. MODELL: Yes, but the feeling is strong about mercurials because the metal itself is so toxic. If the "acid-forming" diuretics are not excreted because of renal insufficiency, eventually the pH of the blood is reduced, and acidemia instead of acid urine is produced.

DR. GOLD: With regard to urea, it has been shown that there are patients who do not excrete urea very quickly, and after doses of the order of 2 or 3 ounces of urea a day the blood urea levels can go up to 250 milligrams per cent; and when they do the patients sometimes become very drowsy. It is not dangerous, but it is an important symptom,

Urea produces in animals and in man symptoms similar to those produced by the barbiturates, in which urea is one of the basic groupings.

DR. TRAVELL: If you give 2 cc. of organic mercurials in the initial dose, do you not sometimes encounter toxic reactions due to idiosyncrasies to these substances?

DR. GOLD: That dose seems rather high.

DR. WHEELER: For four or five years and to hundreds of patients we have given an initial dose of 1 cc. just to be sure they would not get into trouble, but we never saw patients who reacted unfavorably to that dose, and so consequently the tendency now is to give a dose of 2 cc. initially.

DR. GOLD: I would like to warn against it. There are individuals who pass 5 or 6 liters of urine a day after 0.5 cc. A large dose would result in more massive diureses, which could hardly take place without undue strain and distressing symptoms. Of course, a great many patients require larger doses, but one ought to test their tolerance with smaller ones.

Let me tell you about one patient who had an idiosyncrasy. The patient received 1 cc. of mercupurin and nearly died. She developed symptoms of shock within a few hours. Her temperature rose to 103 F. She vomited. She spent the next two weeks recovering from an ulcerative stomatitis. A dose of 1 cc. did a great deal of damage. We then gave doses of the order of 0.05 cc. Even these small doses produced sore gums. We wondered whether this response applied to other mercurial diuretics. Subsequently, we discovered that she could tolerate a dose of 2 cc. of salyrgan without any trouble. Such cases are rare, but they occur.

DR. MODELL: I wonder whether Dr. Wheeler has noticed any difference between the effects of salyrgan and salyrgan-theophylline?

DR. WHEELER: I have not used enough of salyrgan-theophylline to have any opinion about it.

DR. MODELL: How do you feel about the usefulness of the small amount of theophylline—intravenously—which these mixtures contain?

DR. GOLD: The amount of theophylline in any of these compounds is so very small. In the 1-cc. solution of mercupurin, it is only 35 mg. Whatever the reason for the introduction of the theophylline into the compound, it is a fact that the xanthines reduce the local irritant effect of mercury. Mix some bi-

chloride of mercury with a xanthine and inject it subcutaneously; the local effect will be negligible, whereas the same amount of bi-chloride of mercury injected subcutaneously without the xanthine will produce pronounced irritation. The diminished irritant action may be related to the fact, shown by DeGraff and his coworkers recently, that the xanthine promotes the absorption of the mercury from the site of injection.

There is a general trend now to put up organic mercurials in combination with the xanthine, even for intravenous injection. If any of the material is spilled into the subcutaneous tissues, all that results, instead of a slough, is a sensation of pinching, which lasts an hour or two, and disappears without any untoward effects.

STUDENT: If one fails to induce a diuresis with the first few doses of an organic mercurial, how long should one continue to give it?

DR. GOLD: Would you like to answer that, Dr. Wheeler?

DR. WHEELER: There is an important point that I should like to make in this connection. We occasionally do see patients who come into the hospital in severe congestive heart failure and who fail to show diuresis following injections of the mercurial diuretics given during the first few days after admission, who, after several days of rest and other forms of treatment, respond with a marked diuresis to a dose of a mercurial. Now to answer the question more specifically, I should think that if you have given two injections to a patient who was not in severe congestive failure and had observed no diuresis from either, there would be little likelihood that any further doses would be effective, and the further use of the mercurials should be attended with caution.

STUDENT: How rapidly would you say it is safe to remove a massive anasarca from the patient by the use of diuretics?

DR. WHEELER: We remove it as rapidly as possible with theocalcin, ammonium chloride, and mercupurin all at the same time, in addition to whatever other medication, such as digitalis, is being given. As Dr. Gold says, one occasionally sees untoward effects. In addition, many patients may be considerably fatigued by the passage of 6,000 or 7,000 cc. of urine in one day. However, it is our feeling that this may be disregarded when there is urgent need of relieving severe failure. There are a number of reasons why it appears important to reduce the degree of severe cardiac

decompensation as rapidly as possible. For example, a patient with severe passive congestion of the lungs is particularly susceptible to bronchopneumonia, and the risk of this serious complication may be lessened by a rapid reduction in the degree of congestion.

DR. GOLD: I am afraid we have time only for a summary by Dr. Modell.

DR. MODELL: I think that you summed up for us in your introduction, Dr. Gold.

When effective diuretics were added to the list of useful drugs, the lives of many cardiacs who no longer were being benefited by digitalis were prolonged and made tolerable. This is not to be underestimated since, as has been pointed out, patients may respond to hundreds of doses of effective diuretics given regularly over a period of many years. Unfortunately, however, only the cardiac patient can depend on this type of relief.

The choice of a particular diuretic depends on how urgent the need for relief is, whether renal damage is present, whether the patient can conveniently appear at the doctor's office for frequent injections, whether he can bear

the taste of urea, and whether in him the xanthines produce gastric distress.

The mercurials are dependable and, especially in combination with an "acid-forming" diuretic, may induce profound diuresis and dramatic relief of congestive heart failure. On the other hand, the mercurials should be used with caution since, aside from the danger of the mercury, profound diuresis, itself, may cause unpleasant symptoms. There may be a tendency in medical circles today to use appreciably larger doses of the mercurials than are actually needed to induce an adequate flow of urine.

The xanthine diuretics, although quite effective when administered orally, unfortunately produce gastric distress in so many patients that a relatively large proportion refuse to take them; nevertheless, they should be tried.

Urea is still one of our most effective diuretics, and despite its decidedly unpleasant taste, which is its only real disadvantage, it should be used much more widely. It is perhaps the safest of the diuretics.

PSYCHOANALYST ON STAGE EARNS DOCTORS' PRAISE

Probably the most unusual collection of fan letters ever received by an actor is owned by Donald Randolph, the man who has been psychoanalyzing Gertrude Lawrence for more than a year in *Lady in the Dark*. The value of this collection, according to Randolph, is to be measured not by volume but rather by its content and authors. They are letters of praise, criticism, or analysis of Randolph's performance from many of the seventy accredited psychoanalysts practicing in New York City.

As Dr. Brooks, the psychiatrist to whom Miss Lawrence, as Liza Elliott, unburdens her soul, Randolph is the first actor to portray a psychoanalyst at work. Never having been psychoanalyzed himself, not knowing anyone who had been, and never having seen even a reasonable facsimile of an analyst at work on the stage, Randolph approached his role, one might say, as a man in the dark. One of Randolph's nightmares is prompted by his imagining the type of letters he might have received if he had not been guided through rehearsals by Moss Hart, director as well as author of *Lady in the Dark*, who had had considerable experience with psychoanalysis and was able to suggest the proper approach. "I have been called to task by several well-known psychiatrists for minor breaches of psychoanalytical technique and etiquette. Some of the boys are pretty finicky about the fine points of their profession. There's one thing I do which nearly

all of my correspondents have pointed out is unorthodox. Here is a passage from one of these letters: 'It's a rare pleasure to be afforded so splendid an opportunity for identification with an actor on the stage as is furnished to psychoanalysts by the role you portray. The medical doctor, the surgeon and even the veterinarian has seen himself portrayed over and over again on the stage and screen, but never before the psychoanalyst. Perhaps for that very reason I cannot refrain from calling your attention to an incident during the course of your psychoanalysis of Gertrude Lawrence which would never take place at that stage of the analysis. I refer to the scene in which you permit the patient to rise from the recumbent position on the couch and wander about the room while she relates her fantasies and dreams. This happens during what purports to be the first week of the analysis. Such a thing never would be permitted in an actual case. Not until a patient is well on his way to being cured—which usually is not before a year—would a doctor permit a patient to rise from the couch and talk directly to him. Please do not regard this as a serious criticism of either your performance or the play. It is not intended as such. I thought you might be interested in knowing the one point at which you and the character you play veer from strict authenticity.'"

Medical Preparedness

The information printed below with reference to the Blood and Plasma Bank Program of the Medical Division of the Office of Civilian Defense was received from George Baehr, M.D., Chief Medical Officer. The regulations governing grants to hospitals were contained in a release from the U. S. Public Health Service.

Blood and Blood Plasma Bank Program

REGULATIONS for the administration of the Blood and Plasma Bank Program of the Medical Division of the United States Office of Civilian Defense have now been prescribed, and funds are available for grants to assist approved hospitals in establishing blood and plasma banks. Only hospitals within 300 miles of the Atlantic, Pacific, or Gulf coasts are eligible for such grants. After July 1, 1942, these geographical restrictions may be modified, so that grants may be made to inland hospitals. Applications should be addressed to the Chief Medical Officer, United States Office of Civilian Defense, Washington, D. C.

Technical manuals on blood and plasma banks, prepared by the Subcommittee on Blood Substitutes of the Division of Medical Sciences, National Research Council, are now available for distribution on request of any hospital to the Chief Medical Officer, Office of Civilian Defense.

The Red Cross has established eighteen donor centers in various parts of the country, which are successful in obtaining an adequate supply of blood donors for military purposes. Blood for the production of dried plasma for Civilian Defense purposes will also be obtained from these sources.

Hospitals which establish their own blood and plasma banks with the financial assistance of the Office of Civilian Defense are advised to build up their reserves of blood and plasma by expanding blood collection from relatives and friends of patients who are to receive transfusions. A public campaign for volunteer donors that might compete with the work of the Red Cross should be avoided if possible. If public solicitation is necessary, hospitals should appeal to the local chapters of the American Red Cross for assistance in recruiting hospital donors. Blood donor campaigns by agencies other than the Red Cross will tend to confuse the public and may interfere with the blood collection by the Red Cross for the armed forces.

Regulations Governing Grants to Hospitals for Establishing Reserves of Blood Plasma

On April 11, 1942, there was allotted from the "Emergency Fund for the President" to the United States Public Health Service the amount of \$292,500, "to be expended by said Public Health Service in connection with emergencies affecting the national security and defense for procuring and establishing either independently or, subject to regulations to be promulgated by the Surgeon General, by grants to public and private hospitals located not more than 300 miles from ocean or Gulf Coast, reserves of liquid, frozen, or dry blood plasma or serum albumin for the treatment of casualties resulting from enemy action." The following regu-

lations are promulgated to govern the administration of this allotment:

Section I. Eligibility for Grants.—Preference shall be given to hospitals serving communities whose geographical locations imply a likelihood of civilian casualties from enemy action, and which are inadequately equipped to handle such casualties.

To be eligible for a grant, a public or private hospital located not more than 300 miles from ocean or Gulf Coast* shall:

1. Have a capacity of not less than 200 beds, exclusive of bassinets, provided that two or more smaller hospitals totaling 200 beds may submit a cooperative project designating one of the participating hospitals as the grantee.

2. Be on the approved list of the American College of Surgeons and the Hospital Register of the American Medical Association.

3. Have on the professional staff a physician whose qualifications are the equivalent of those required by the American Board of Pathology for its diplomates.

Section II. Approval of Plans.—A grant shall cover a period of not more than twelve months following the approval of the plan, or not beyond June 30, 1943, and may be used only for the purpose of equipment necessary for the preparation of liquid or frozen plasma, reconditioning or minor alterations of existing quarters, necessary travel and subsistence allowance of \$6.00 a day to cover a training period, if required, of not more than one week, for the physician directing the blood plasma project, and temporary salaries of personnel necessary for the establishment of a blood and plasma project.

The maximum grant for one hospital is \$2,000.

A hospital desiring to receive a grant shall submit a plan to the Chief Medical Officer, Office of Civilian Defense, who is authorized to receive such plans on behalf of the Surgeon General of the United States Public Health Service. A plan shall contain the following information:

1. The number of hospital beds, classified according to use.

2. The name and qualifications of the physician who will direct the plasma project.

3. Description of present blood and plasma project, if any.

4. The type and amount of plasma reserves which the institution desires to prepare.

5. The delivered price of equipment necessary to complete the existing facilities for preparing such plasma—such items to be numbered and described in accordance with the equipment inventory in "A Manual on Citrated Normal

* The Appropriation Act for the fiscal year 1943 may not limit grants to hospitals within this geographical area.

Human Blood Plasma," issued by the Office of Civilian Defense—or equivalent approved substitute equipment.

6. The materials or labor, if any, needed for adapting existing quarters to the needs of the blood plasma project.

7. The salaries, if any, to be paid additional personnel until the plasma reserve has been prepared. Salary items shall also show the proposed periods of employment for each individual and the proposed monthly rates of pay.

When a plan is recommended by the Chief Medical Officer of the Office of Civilian Defense for the approval of the Surgeon General, the hospital will be furnished a budget and acceptance form to be signed, notarized, and returned to the Chief Medical Officer, Office of Civilian Defense.

Section III. Conditions of Grants.—1. The hospital shall agree to build up a plasma reserve of at least one unit per bed within three months after delivery of the necessary equipment. A unit of plasma is that amount derived from 500 cc. of citrated whole blood, consisting of about 250 cc. of liquid plasma.

2. The agreed amount of plasma reserve shall be maintained for use without charge and only for treatment of casualties caused by enemy action. The reserve shall be released for use in other local hospitals for this purpose on order of the local Chief of Emergency Medical Service and for transfer within the state on order of the State Chief of Emergency Medical Service, or transferred from one state to another on the order of the Regional Medical Officer, Office of Civilian Defense.

3. Liquid plasma shall be kept from being outdated by replacement of older by newer plasma. Replaced units may be utilized for current needs of the hospital in the treatment of its regular patients, provided the plasma reserve shall not be allowed to fall below the stated minimum.

4. All plasma shall be prepared in accordance with manuals of the Office of Civilian Defense prepared by the Subcommittee on Blood Substitutes of the National Research Council.

5. The hospital shall agree to continue the plasma project for its current needs after the expiration of the Federal Grant and to maintain for the duration of the war the minimum stated reserve; thereafter the reserve may be used by the hospital without restriction.

6. A record shall be kept of all blood donors,

including their blood types, to expedite obtaining donors for emergencies.

7. No funds made available under the grant shall be used for the payment of blood donors.

8. Any blood plasma project under this program shall be subject to inspection by authorized representatives of the Surgeon General of the Public Health Service.

Section IV. Method of Payment.—Payments will be made on a reimbursement basis for expenditures made in accordance with the approved budget. Applications for reimbursement shall be notarized and addressed to the Chief Medical Officer, Office of Civilian Defense. The procedure for payment will be as follows:

1. Payments from the allotment to cover the purchases of nonexpendable equipment aggregating \$300 or more will be paid upon receipt from the authorized administrative head and accounting officer of the hospital of an itemized statement of the purchases, supported by invoices showing the date of delivery of such equipment.

2. Payment will be made for the authorized training expenses of the physician who is to direct the blood plasma project, whenever the hospital presents a notarized claim itemizing the travel and per diem allowance incident to the training.

3. Reimbursement for other items of the approved budget will begin only after actual production of blood plasma is started. During the first three months of production, reimbursement will be made on a monthly basis, and quarterly thereafter, for the duration of the grant. Such reimbursement will be made only upon receipt of a report form prescribed by the Surgeon General from the institution showing expenditures incurred during the period, total plasma prepared during the month, and the total reserve on hand to date.

4. Payments may be withheld, and plasma produced as part of this project may be transferred by the Surgeon General from any hospital which fails to meet the conditions of the grant or to comply with the regulations.

5. Each hospital shall submit monthly reports during the period of the grant, showing the amounts of plasma on hand and used; thereafter, for the duration of the war, the hospital shall submit such reports quarterly on its use of the plasma.

6. Hospitals shall submit promptly reports including clinical abstracts of any untoward experiences encountered in the use of plasma, for the duration of the war.

N. Y. U. OFFERS SPECIAL COURSES

In order to meet the national emergency and to enable graduate students to obtain basic training of value in support of the war effort, the Graduate School of Arts and Science, New York University, is offering the following courses as part of their regular twelve weeks Summer Session, June 29 to September 18:

Haematology and Micro-Technique (Biology)

Biochemistry and Nutrition (Biology)
Advanced Laboratory Techniques (Physics)
Semi-Microqualitative Organic Analysis (Chemistry)
Organic Synthesis (Chemistry)

All of the above courses may be applied as credit toward an advanced degree.

Postgraduate Medical Education

Programs arranged by the Council Committee on Public Health and Education of the Medical Society of the State of New York will henceforth be published in this section of the JOURNAL. Members of the committee are Oliver W. H. Mitchell, M.D., chairman (428 Greenwood Place, Syracuse); George Baehr, M.D.; and Charles D. Post, M.D.

Cancer Teaching Day

A Cancer Teaching Day will be held in Buffalo on Thursday, June 18, at 2:00 P.M., in the Hotel Statler.

Participating organizations will be the Erie County Medical Society, the University of Buffalo School of Medicine, the Eighth District Branch of the New York State Medical Society, the Medical Society of the State of New York, and the New York State Department of Health, Division of Cancer Control.

The following program will be given:

Cancer of the Larynx—Early Diagnosis and Criteria for the Selection of Methods of Treatment. (Illustrated by motion pictures and lantern slides.)

Dr. Chevalier L. Jackson, professor of clinical bronchoscopy and esophagoscopy, School of Medicine, Temple University, Philadelphia.

Hematuria and Cancer of the Genitourinary Tract.

Dr. George F. Cahill, professor of urology, College of Physicians and Surgeons, Columbia University, New York City.

Carcinoma of the Breast—Diagnosis, Treatment, and Results.

Dr. Frank E. Adair, executive officer, Memorial Hospital, New York City.

Surgery and Radiation in the Treatment of Malignancies of the Colon and Rectum.

Dr. Thomas E. Jones, surgeon, Cleveland Clinic, Cleveland, Ohio.

Recent Studies in the Production of Cancer by Chemical Compounds, the Conditioned Deficiency as a Mechanism.

Dr. Cornelius P. Rhoads, director, Memorial Hospital, New York City.

A dinner will be held at 6:30 P.M., followed by the last talk. Dinner tickets may be secured at the Registration Desk.

On May 14, Dr. Haven Emerson, of The De Lamar Institute of Public Health, Columbia University, College of Physicians and Surgeons, spoke at a meeting of the St. Lawrence County Medical Society at Ogdensburg. His subject was "The Private Physician's Place in Public Health."

AMBULANCE UNIT DOING GOOD WORK

To the Editor of The New York Times:

I should like to refer to the report sent by Harrison Forman from Chungking concerning the work of the Friends Ambulance Unit in China and Burma. I have just arrived in this country from China, having spent some five months as a member of this unit, and I think it should be pointed out that many of the trucks and ambulances used in evacuating the medical supplies from Burma were a gift from the British-American Ambulance Corps.

The unit in China is composed of British, American, and Chinese representatives and has been generously financed by the United China Relief. I feel that the work of the unit is especially significant, because it represents a joint American and British effort of cooperation and sympathy with the Chinese people.

The FAU is doing two types of work in China. One is purely medical, in which our five doctors are using the mobile hospital unit which was sent

out from this country, and doing a great deal of major surgery. The other—and this is the chief relief problem in China today—is in distributing medical supplies to hospitals all over the country. We have organized a convoy system, by which we are transporting drugs and other supplies for the International Relief Committee, the National Health Administration, and the Chinese Red Cross. Of great help in keeping the trucks in good condition is the mobile repair shop, which also was built in this country.

Although the Burma Road has now been cut, thus drastically limiting the supplies of gasoline that can be taken into China, the work can still continue. It is possible to convert trucks from gasoline-burning to charcoal-burning, and several of our trucks have already been converted and are performing well.

Why let a busy mother upset your formula balance?

THE OPTIMAL NUTRITION which your baby feeding prescriptions provide... may be lost through errors in formula preparation.

For even the best-intentioned mothers may make mistakes in measuring. Or leave out important supplements. Or fail to follow instructions completely.

Biolac makes such formula errors all but impossible, because:

1. Formulas are made by simply diluting Biolac with water.
2. Biolac provides completely for *all* the nutritional requirements of early infancy except for vitamin C.
3. No supplementary formula ingredients are necessary.

Biolac is prepared from whole milk, skim milk, lactose, vitamin B₁, concentrate of vitamins A and D from cod liver oil, and ferric citrate. It is evaporated, homogenized, and sterilized.

4. The adequate carbohydrate content of Biolac is processed in the milk, is in equilibrium and is sterile.

5. The nutritional completeness of Biolac is guaranteed by strict laboratory control of manufacturing operations and assays of product composition which are recognized in its A.M.A. Council acceptance.

Thus in prescribing Biolac you have these extra assurances that your babies will actually receive in their formulas the optimal nutrition you prescribe.

Biolac nutritional values equal or exceed recognized standards. For complete information, write Borden's Prescription Products Division, 350 Madison Ave., New York, N. Y.

Medical News

We Thank the County Society Secretaries

... who sent in news of their county activities in answer to the memorandum of May 8. We want to hear from all of you regularly. The deadline dates for copy are the twenty-eighth and thirtieth of each month, respectively. Even though many of the regular society meetings have adjourned for the summer there is still much local news of great interest. We again urge you to forward it to us, and we should appreciate your having the copy typed double spaced.—*Editors.*

County News

Albany County

At the March meeting of the county society, held on the twenty-fifth in the auditorium of the Albany College of Pharmacy, Dr. Arthur J. Bedell, of Albany, spoke on "Ophthalmoscopy and the Conservation of Health."

A comprehensive demonstration of kodachrome slides stressed the diagnosis and prognosis of diabetes, tuberculosis, syphilis, nephritis, and hypertension. The extreme importance of ophthalmoscopy was explained, new photographs were presented, and questions were answered.

Because of the increasing interest in diseases of the Far East, Dr. Bedell showed some of his unusual pictures of leprosy.

Discussion was by Dr. James F. Rooney, Dr. R. J. Erickson, and Dr. Rudolph Reudemann, Jr.

Luncheon was served by the Woman's Auxiliary, following the meeting.

At the meeting of the county society on April 22, Dr. David M. Bosworth, of New York City, spoke on "Shoulder Lesions," illustrating his talk with colored slides and colored movies.

Discussion was by Dr. Philip L. Forster and Dr. Thomas J. O'Donnell.

At a special observance of Mother's Day in Albany, officers of the Albany County Medical Society pointed out that the city of Albany is tied for second place for the lowest maternal death rate among American cities, and that figures reveal the Albany birth rate to be steadily increasing.*

Among four persons awarded honorary degrees by Rensselaer Polytechnic Institute, Troy, at Commencement on May 17, was Dr. John A. Sampson, Albany County surgeon and professor of gynecology at Albany Medical College, as well as senior gynecologist at Albany Hospital.*

Broome County

The March meeting of the county society was held at the Nurses Residence, Charles S. Wilson Memorial Hospital, Johnson City. The members of the society were dinner guests of the medical department of the Endicott-Johnson Corporation.

The speaker of the evening was Dr. Reginald Fitz, of Boston, whose subject was "Clinical Aspects of Jaundice."

At this meeting the following motion was passed: "Resolved that the treasurer of the Broome County Medical Society be and hereby

is empowered to withdraw from the society's savings or interest account a sum sufficient to purchase one \$1,000 Government Defense Bond, Series G."

At the meeting on April 14, Dr. Philip D. Allen, attending surgeon, Knickerbocker and Bellevue hospitals, New York City, presented "Photochrome Photographs of Fresh Surgical Material."

The meeting on May 12 was held in the auditorium of the Binghamton City Hospital. Dr. Henry C. Marble, assistant professor of surgery, Harvard University, spoke on "Trauma of the Hand." Dr. Marble stressed particularly the care of wounds under war conditions, where the surgeon is limited in his choice of procedures. He also noted the great progress that has been made in the care of the wounded since the last war, particularly in the use of sulfa drugs in open wounds.

A short course in First-Aid instruction was given for members of the society on March 20 and 27 at Phelps Hall, Binghamton City Hospital. The course was given by Dr. John R. Montgomery, formerly a Red Cross physician.

Dr. William Creighton Garvin, superintendent of the Binghamton State Hospital for eighteen years, died March 3, after a long illness. Dr. Garvin was born on November 30, 1873, in Philadelphia. He was widely known in eastern medical circles. He was a student of psychiatry and a well-known figure in the health and hygiene field in New York State. After he was graduated from the College of Physicians and Surgeons of Columbia University in 1903, he served as an intern in the City, the Lying-In, and the Foundling hospitals in New York City. He became junior physician at the Manhattan State Hospital, Ward's Island, New York City, and in 1915 was appointed to the King's Park Hospital. In 1918, he became superintendent of this institution and remained there until his appointment as superintendent of the Binghamton State Hospital in 1924.

Dr. Henry C. Smith, 29 Riverside Drive, Binghamton, has entered active service in the Navy Medical Corps, with the rank of Lieutenant-Commander. Dr. Smith is at present stationed at the Chelsea Naval Base Hospital, Chelsea, Massachusetts.—*H. Jackson King, M.D., Secretary.*

Bronx County

At the regular meeting of the county society on March 18, there was a symposium on "Pe-

Presenting the "KOROMEX SET COMPLETE"

*Koromex Set Complete** provides the long expressed need for a compact unit containing the three important items used for approved contraceptive technique. This attractive and strongly built case is identified by an easily removed label, convenient for dispensing or prescription purposes. To order or prescribe, merely write, "*Koromex Set Complete. Diaphragm Size_____*".

KOROMEX DIAPHRAGM—The outstanding, most durable diaphragm made. Backed by the most extensive record in clinical use ever attained by any diaphragm. In special sanitary pouch.

KOROMEX TRIP RELEASE INTRODUCER—The latest development in introducers. Swivel tip facilitates usage.

KOROMEX JELLY and H-R EMULSION CREAM—Both preparations have equally high spermicidal value, but differ greatly in the amount of lubrication afforded. A tube of each is here offered so the patient may determine for herself which type of preparation better meets her aesthetic requirements and her personal preferences.

* Price of the Koromex Set Complete is only that of the Koromex Diaphragm and the Koromex Trip Release Introducer.

Holland-Rantos
Company, Inc.

[Continued from page 1106]

ripheral Vascular Diseases": "Medical Aspects of Peripheral Vascular Disease," by Dr. Irving Sherwood Wright; "Surgical Aspects of Peripheral Vascular Disease," by Dr. Beverly Chew Smith; and discussion, by Dr. Gamliel Saland and Dr. Thomas J. O'Kane.

Following the executive session at the meeting on April 15, Dr. John J. Moorhead, of New York City, spoke on "Surgical Methods During the Pearl Harbor Attack," followed by Dr. Morris Fishbein, whose subject was "The Procurement and Assignment Service."

Dr. Hugh H. Young, of Baltimore, was the speaker at the county society meeting on May 20. He talked on "Hypertrophy and Cancer of the Prostate." Discussion was led by Dr. Benjamin Barringer and Dr. Isidor Palais.

Dr. Frederick W. Williams, vice-president, presided in the absence of Dr. Abner Stern who reported for active duty in the Army on May 14.

Cayuga County

Dr. John M. Swan, of Rochester, executive secretary of the New York State Committee of the American Society for the Control of Cancer, was the guest speaker at a public meeting held at the Chamber of Commerce in Auburn on May 6. His subject was "The Prevention and Control of Cancer." The meeting was sponsored by the Cayuga County Medical Society, the Cayuga Health Association, and the Auburn Community Council. Dr. Harry S. Bull, chairman of the Cayuga County Committee of the American Society for the Control of Cancer, presided.*

Chautauqua County

"The Emergency Medical Service is rapidly gaining completion here under the capable supervision of Dr. George W. Cottis as chief. No less than 104 medical professionals are identified with the unit, including every doctor in the city, with Dr. W. Gifford Hayward as vice chief," says the *Jamestown Post Journal*, May 7.

Chemung County

The regular March business meeting of the county society, together with the annual meeting of the Health and Credit Service, Inc. (the Doctor's Business Bureau) was held on March 25 at the Arnot-Ogden Memorial Hospital.

A special meeting of the county society was held on May 8, in the society rooms at the Arnot-Ogden Memorial Hospital.—*H. L. Walker, M.D., Secretary.*

At this meeting the society took the position that deferment from U. S. service should not be asked for physically fit doctors under 45 years of age if they are needed in the armed services or other governmental work.*

The *Elmira Advertiser*, of May 5, carried this news:

"Dr. H. Curtis Bowser and Dr. Earle G. Ridall will leave May 14 for active duty with the U. S. Army Medical Reserve Corps.

"Dr. Bowser, who has been practicing medicine here for about two and one-half years, has received a first lieutenant's commission and will be assigned to Chanute Field, Rantoul, Illinois.

"Dr. Ridall has been commissioned a captain

and has been assigned to Barksdale Field, Shreveport, Louisiana. He has been associated with Dr. Arthur C. Smith since 1937.

"In line with the Army's calling into service of younger physicians, Dr. Ross E. Hobler expects to be commissioned and called to duty soon."

Dutchess County

Dr. John J. Moorhead spoke on his surgical experiences at Pearl Harbor at the regular meeting of the county medical society held on March 13 at the Amrita Club, Poughkeepsie.

The society had as its speaker at the April meeting, Dr. Howard W. Neail, assistant medical examiner of the City of New York (Queens County), who spoke on his work.

At the regular meeting of the society on May 13 a technicolor motion picture with sound was shown on "Sex Hormones, Physiology, Diagnosis, and Therapy," through the courtesy of Parke, Davis and Company.

Erie County

At the meeting of the county society held on March 24, Dr. Harold F. R. Brown, chairman of the General Practitioners' Program Committee, introduced the guest speaker of the evening, Dr. William D. Stroud, of Philadelphia, a well-known cardiologist, whose subject was "Coronary Disease." In speaking to the general practitioners, whom Dr. Stroud called the "real doctors," he said that he would take the practical side of the subject, namely, treatment, including also points in diagnosis, says the *Bulletin*.

Dr. Stroud stressed many times in his talk the importance of the physician taking a more optimistic and reassuring attitude toward the patient with cardiovascular disease, to avoid the damage done through fear and apprehension. He said that heart disease as a cause of death was given too much publicity through the press in reporting deaths, whereas cancer, tuberculosis, and the other common causes of death were always omitted from obituaries, and that this naturally had a very bad effect on the patient who knew he was suffering from a cardiovascular disease.

He also brought out forcibly that in treating hypertension and coronary disease, the physician should be especially careful not to generalize too much in the matter of diet.

At the stated meeting of the society on April 21, the guest speaker was the Honorable George L. Grobe, United States District Attorney.

A Cancer Teaching Day will be held on Thursday, June 18, at 2:00 p.m. in the Terrace Room, Hotel Statler in Buffalo.

Fulton County

The county society held a regular monthly meeting on April 16, at the Eccentric Club, Gloversville. There were twenty-five members present. Mr. John Lafabregue, vice-president of the local County Bank, addressed the society on the subscription of Defense Bonds on a monthly basis. He said that the banks would deduct the necessary amounts regularly from the checking accounts of purchasers.

[Continued on page 1110]

[Continued from page 1108]

Dr. Philip D. Allen, associate surgeon at Bellevue Hospital, New York City, showed some excellent kodachrome pictures of a wide variety of surgical, pathologic specimens.

The following members of the Fulton County Medical Society are now with the Armed Forces: Drs. A. F. Goodwin, Robert S. Kunkel, F. C. Crump, W. H. Raymond, and Morris Alpert. —*Louis Tremante, M.D., Secretary.*

Genesee County

The *Batavia News*, of May 5, carried the following item:

"Commissioned a first lieutenant in the United Army Air Corps, Medical Division, Dr. Alfred L. George, of Oakfield, is to report for active duty at Manchester, New Hampshire, air base on May 18 and thus become the first Genesee County physician to answer the call to the colors since war was declared. On May 7, Dr. Robert H. Reddick, of Gowanda, is to assume Dr. George's practice."

Jefferson County

The second meeting of the course in "Arteriosclerosis and Ageing" was held at the Black River Valley Club on April 16, with dinner at 6:30 p.m.

The subject was "Pathological Aspects," by Dr. Sigmund L. Wilens, associate professor of pathology, New York University, College of Medicine.

The series of broadcasts sponsored by the county medical society came to a close on May 11 when Dr. V. T. Rear spoke on "Mental Hygiene." The talk on May 4 was by Dr. J. L. Crossley and his subject was "Maternal Health."*

Kings County

Lt.-Col. William E. Lippold, M.D., then Medical Executive Officer, Second Military Area (now president, Medical Dept. Officer Recruiting Service, Newark, New Jersey), spoke to the county society at its regular March meeting. His subject was "Medical Service in the Army." Colonel Lippold was formerly a Brooklyn gynecologist.

Another speaker at this meeting was Dr. William F. Braasch, who is the chief consulting urologist at the Mayo Clinic, Rochester, Minnesota. His subject was "Recent Progress in the Treatment of Disease Involving the Urinary Tract."

At the regular meeting in April, Dr. William Thalheimer, who is in the Division of Health Research, New York City, spoke to the society on "Shock and Infections in Wartime and Their Treatment with Human Convalescent Serum and Blood Substitutes."

Dr. Herman N. Bundesen, president of the Health Department of the city of Chicago, spoke on "Prematurity."

The Pediatric Section of the county society had as its speaker in March Dr. Arthur M. Yudkin, of New Haven, Connecticut, whose subject was "Diseases of the Eye in Infancy and Childhood." At the April meeting, Drs. M. Murray Peshkin and Raphael Schillinger, of New York City, spoke on "Sinusitis in Childhood."

Livingston County

The Emergency Medical Services for Livingston County, under the direction of Dr. Gerald E. Murphy, of Mount Morris, have been organized and drilled. Equipment is rapidly being acquired for the First-Aid teams and will be complete by June 1. Casualty stations have been established throughout the county.

A dinner in honor of Dr. F. R. Driesbach, of Dansville, and Dr. F. V. Foster, of Caledonia, was held at Genesee on April 23, and was attended by twenty-five members and guests of the society. The occasion was the completion of over fifty years in medicine by each of these men. The speaker, Dr. W. D. Johnson, of Batavia, traced the development of medical practice from the early part to the end of the nineteenth century. Presentation of Lord Elgin watches to each doctor was made by Dr. Johnson. Dr. Foster and Dr. Driesbach responded by giving short addresses. —*Gerald E. Murphy, M.D., Secretary.*

Monroe County

At the regular meeting of the county society, held on March 17 at the Academy of Medicine in Rochester, the speaker was Dr. Foster Kennedy, professor of neurology, Cornell University Medical School, and neurologist at Bellevue Hospital. His subject was "Functional Nervous Conditions Associated with Warfare."

Preceding the lecture, a subscription dinner was held at the University Club.

A regular meeting of the county society was held May 19. The speaker was Dr. Louis H. Bauer, of Hempstead, Long Island, whose subject was "Aviation Medicine."

The new president of the Rochester Academy of Medicine is Dr. John Aikman, elected May 5.

Other officers are: vice-president, Dr. Charles B. F. Gibbs; secretary, Dr. Robert L. Brown; treasurer, Dr. Harold H. Baker; and trustees for three years, Dr. Benedict J. Duffy, Dr. John J. Finigan, and Dr. Albert D. Kaiser.

Dr. Joseph W. Howland, graduate of the University of Rochester and instructor in the university's School of Medicine, was voted the annual Taylor Instrument Company's award for his paper on "The Nature of the Plasma Proteins and Their Use in Clinical Medicine."*

"Full-scale vaccination of children, special attention to prenatal care for mothers, including special diets, and a definite effort to prevent home accidents are patriotic duties," Dr. Albert D. Kaiser, a member of the State Health Preparedness Committee, declared during a Child Health Day program.

He addressed 200 members of the Monroe County Public Health Nursing Committee and representatives of county health agencies at a luncheon meeting in Dreamland Inn, Sea Breeze. His topic was: "Safeguarding the Health of the Child in Wartime."*

Nassau County

At the county society meeting on March 31, held in the Cathedral House, Garden City, four papers were presented by the Nassau Surgical Society. They were: "Present-Day Treatment of Burns," by Dr. J. Wesley Bulmer; "Use and

GOLD PHARMACAL Co., New York

THE VACATION PICTURE—1942

Vacations may not be "as usual" due to transportation curtailments in one way or another, and dim-outs have created new problems for the resorts, but nevertheless, preparations have been made on a large scale by resorts in the East to handle a rush of business from June 1 until the leaves fall.

This time of the year has always brought the same questions before the family—"where shall we go" and "how shall we get there"—but now they are even more significant, even as are the rest periods themselves. In most cases, presumably, these questions will be solved by entraining for points nearest home and it is not unlikely that the man of the family, if he sends the wife and children to the seashore or mountains for the "duration," will have to forget the week end reunions this year if the family car has to go on a diet.

Still with many excellent places within his own state or adjacent states, and within a few hours' train ride, this

problem may not become so acute. On the other hand, there is still the possibility that transportation by train may also be disrupted somewhat, so dad may have to sacrifice even the week end get-together.

To the Travel Industry, this does not present as gloomy a picture as it may to dad, for there is every indication that vacations for the entire family (excluding dad) will be for longer periods this year. Not so much that fear of air raids may cause some to send the families away to safer places for as long a time as school vacations will permit, but because it may prove the only solution to supplanting the frequent auto trips to the beach or lake.

How will all this change in vacation planning affect health? Well, if we are forced to take better and bigger vacations away from smoky cities and fume-infested highways—it should do the country at large some real good—not to mention learning again how to walk for exercise.

THE PHYSICIANS' HOME

WHO STARTED IT? A group of physicians in 1918. They recognized the tragedy of their colleagues who were destined to go to local or state charitable agencies. The purpose was to establish and create means, to offer help, and maintain self-esteem for those deserving professional men and women. *THE PHYSICIANS' HOME represents the efforts of this group.*

WHOM DOES IT SERVE? Members of the medical profession of New York State, on recommendation from their local county medical society.

WHERE DOES IT SERVE? In their own community or as our guests.

WHO ARE OUR GUESTS? Aged, indigent physicians in good standing or widows of physicians.

WHO SUPPORTS IT? Members of the medical profession in the State of New York by voluntary contributions and legacies.

We appeal to the profession for continued support for this worthy charity

Make checks payable to: THE PHYSICIANS' HOME, 52 E. 66th St., New York

Misuse of Iodine in Treatment of Thyroid Patients," by Dr. John N. Shell; "Importance of Human Bites," by Dr. Otho C. Hudson; and "Pregnancy Complicated by Tumors in the Pelvis," by Dr. Aaron L. Higgins.

"Diagnostic Problems and Procedures in Chronic Pulmonary Diseases" was the topic of the scientific session of the meeting of the county society held on April 2 at the Nassau County Sanatorium. Dr. James C. Walsh, medical director, Nassau County Tuberculosis Hospital, was the chief speaker.

An open meeting for all members of the society and their friends was held on May 13, in cooperation with the County Nutrition Council. The speaker was Dr. R. R. Williams, chemical director of the Bell Telephone Laboratories. Dr. Williams is chairman of the Health Committee for the National Research Council on Foods and Nutrition. Dr. James C. Walsh discussed the relationship of nutrition to tuberculosis.

New York County

Plans for an intensive course in the medical aspects of chemical warfare to be given physicians of New York State were made on May 6 at a meeting held at The New York Academy of Medicine in New York City. Assemblyman Lee B. Mailler, chairman of the Health Preparedness Commission of the New York State War Council, presided.

Physicians from New York City, who recently completed a four-day course in treating victims of chemical warfare, attended the meeting and decided on the standards and curricula they will follow in giving a similar course to eighty-five doctors who are acting as local chiefs of Emergency Medical Services in the cities and counties of the state.

Among the doctors who attended the meeting were Dean Willard C. Rappleye, of the College of Physicians and Surgeons, Columbia University; Dean J. A. W. Hetrick, of the New York Medical College of Flower and Fifth Avenue hospitals; Dean Currier McEwen, of the New York University College of Medicine; Dean William S. Ladd, of the Medical College of Cornell University; and Dean Alonzo Curran, of the Long Island College of Medicine, Long Island University; Dr. E. S. Rogers, assistant commissioner of Medical Administration, State Department of Health; Dr. Edwin M. Bernecker, commissioner of hospitals and chief of the Emergency Medical Services for New York City; Dr. O. W. H. Mitchell, of the State Medical Society of Syracuse, and deans of the four upstate medical schools.

Mr. Mailler announced the appointment of David Rutstein, director of the Cardiac Bureau, New York State Department of Health, to the position of deputy state medical officer for gas protection in the Emergency Medical Service.

At the monthly meeting of the county society on May 25, held in The New York Academy of Medicine, Maj. Henry E. Miller, of the Chemical Warfare Corps, U. S. A., and Capt. Reynolds Hayden, district medical officer, U. S. Navy, were the guest speakers.

Oneida County

The March meeting of the Utica Academy of Medicine had Dr. Herbert D. Adams as guest speaker. Dr. Adams, a member of the surgical staff at Lahey Clinic, Boston, spoke on "Diseases of Thyroid." At the outset he said that diseases of thyroid are still complex and their treatment chiefly surgical.

Dr. H. L. Pender opened the discussion of Dr. Adams' paper, which was continued by Dr. B. di Iorio, Dr. Edward R. Evans, Dr. Fred Jones, Dr. Lucy Cobb, and Dr. Hyzer Jones.

Dr. Willard H. Willis presented the preliminary paper, "Clinical Implications of Recent Studies of Iron Transportation and Utilization." Dr. T. Douglas Kendrick led the discussion.

At the April meeting of the Utica Academy of Medicine Dr. Edgar Burke, chief surgeon and assistant medical director, Medical Center, Jersey City, New Jersey, spoke on "Some Aspects of Biliary Tract Surgery." Dr. Dan Mellen opened the discussion.

Dr. W. P. Hall also spoke at this meeting, and his subject was "The Glaucomatous Eye." Dr. Walter Duggan opened the discussion.

The Maimonides Medical Club feted five of its members who have enlisted for Army service at a dinner on April 30, in the Hotel Utica.

The guests of honor are seeking commissions and hope to be in active service by June 1.

The physicians are: Dr. Eliot M. Friedman, Dr. Herman J. Segaul, Dr. Arthur A. Kaplan, Dr. Jack Getzlek, and Dr. Harry Freedman.

Dr. J. J. Wineburgh, president, was in charge of entertainment. Dr. A. T. Goldstein, Dr. Charles Greene, Dr. Harold Katzman, Dr. Morris Rower, Dr. David Harris, Dr. Harvey Cummings, Dr. Stuart Krohn, and Dr. Paul Cahn spoke.*

Dr. Martin Smederling will join the Oneida County Hospital staff July 1, Dr. Robert L. Bartlett, superintendent, has announced.*

Onondaga County

At the March meeting of the county society, Dr. Henry H. Ritter, professor of clinical surgery, New York Post-Graduate Medical School, Columbia University, discussed "Fractures in General—the Treatment of Common Fractures."

From the *Onondaga Bulletin*:

On April 7 Dr. R. C. Farrow discussed "Acute Subacromial Bursitis and Its Treatment by Needle Puncture." This procedure consists of inserting two needles in the bursa and washing it out with saline solution. The results in the acute cases are gratifying enough to warrant its continued use. The discussion was opened by Dr. Richard S. Farr and continued by Dr. George Lynch and Dr. William Pelow.

The second paper was read by Dr. Floyd R. Parker on "Acute Iliac Adenitis—Report of Two Cases in Children." This condition usually results from infection of the lower extremities, but may come from infections elsewhere.

Dr. Julius Voehl's paper was on "Erythema Induratum (Bazin's Disease)—Report of Two Cases." This is one of the manifestations of tuberculosis of the skin, of which there are many. He demonstrated by lantern slides the appearance of the lesion, and also microscopic

"DON'T BLAME SCIENCE"

In a recent issue of the *Saturday Evening Post*, the editor remarked that "Science is often charged with being an accomplice in the waging of war." He stated that discoveries admittedly have increased the scope of warfare, but it is overlooked that the tools devised are equally useful for human benefits in the hands of men of good will.

Quoting Dr. Albert F. Blakeslee, retiring president of the American Association for the Advancement of Science, the *Post* editor reported this man's reply to the critics of science.

Dr. Blakeslee had shown that while science has added to the mortalities of war in one way, it has more than offset them in another. Figures supplied by the Surgeon General's office revealed that deaths among Ameri-

can forces due to battle injuries increased from fifteen per 1,000 in the Mexican War to thirty-three in the Civil War and fifty-three in the first World War. The death rate of soldiers from disease, however, was reduced from 110 per 1,000 in the Mexican War to sixty-five in the Civil War and nineteen in World War I. So for all the increased deadliness of modern weapons, the net result has been an actual reduction in the risks to life in the fighting forces. "And scientific advance is still further reducing the risks," added the editor.

There may be some measure of comfort to the mothers and fathers of those in the service of our flag in such facts—but there is still the problem for science to eliminate deaths of warfare entirely.

[Continued from page 1112]

sections. The discussion was opened by Dr. Leon Griggs and continued by Dr. W. L. Weeden.

Dr. R. W. Urquhart addressed a joint meeting of the county society and the Syracuse Academy of Medicine on May 12. His subject was "Problems of War Medicine and Surgery in England During 1940 and 1941." Dr. Urquhart saw two years of service in the ranks of the Medical Corps in the last war. He has been a lecturer on the staff of the Department of Pathological Chemistry, Faculty of Medicine, University of Toronto, since 1925.

Dr. Thomas F. Laurie, Dr. E. C. Reifstein, and Dr. E. S. Van Duyn, all of Syracuse, and Dr. Stuart B. Blakely, of Binghamton, are members of the medical advisory board of the New York State Federation for Planned Parenthood, which recently was in session in New York City.

"An increasingly sympathetic attitude is being displayed by medical associations toward child spacing work," Dr. Claude C. Pierce, medical director of the federation, said at the annual meeting.

"During the month of April, two states, Tennessee and Florida, have passed resolutions indorsing child spacing," Dr. Pierce announced. "The resolution in each state was sponsored by the maternal and child welfare committee of the State Medical Association and was to the general effect that child spacing, an important part of preventive medicine, should be kept in the hands of the medical profession.

"In each of these states, the House of Delegates and the medical association approved the resolution," Dr. Pierce said. "This means that in these two states there are no impediments against child spacing work being incorporated as a part of the regular program of the state and county public health programs. It is an encouraging fact to us of the Planned Parenthood Federation that the medical profession is giving its official indorsement to child spacing work."*

Ontario County

The regular second quarterly meeting of the county society was held at the Clifton Springs Sanitarium and Clinic, in Clifton Springs, on April 14. A dinner preceded the scientific session when Dr. A. M. Wedd, of Rochester, New York, spoke on "Hypertension."

Orange County

The Committee on Public Health and Education arranged for a series of three two-hour lectures which were on the use of sulfa drugs, given in Middletown on May 12, 19, and 26.

The March monthly meeting at the St. Francis Hospital, Port Jervis, stressed the role of physicians and hospitals in civilian defense.

The March meeting at the St. Luke's Hospital, Newburgh, included a talk on hypertension nephritis by Dr. Herbert Chasis, of New York University.

The monthly meeting at the Horton Hospital in Middletown included case reports on catarrhal jaundice and carcinoma of the thyroid.
—N. P. Cosco, M.D., Secretary.

Queens County

The Friday afternoon lectures, at 4:30 p.m., sponsored by the Graduate Education Committee of the Medical Society of the County of Queens, were:

April 3—"Office Treatment of the Ambulatory Diabetic," by Dr. William S. Collens.

April 17—"Preventive Methods in Certain Tropical Diseases," by Dr. Zacharias Bercovitz.

May 1—"Some Preventable Errors," by Dr. John C. Gerster.

May 15—"Sterility," by Dr. I. C. Rubin.

The April stated meeting was devoted to the subject of obstetrics, and the program was as follows:

April 21, 8:30 p.m.—Dr. William E. Studdiford conducted a "Symposium on Obstetrics."

The subjects and speakers were:

"The Treatment of Postpartum Hemorrhage"—Dr. Arthur M. Reich.

"The Classification and Treatment of Hypersensitive Conditions Associated with Pregnancy"—Dr. Irwin Wellen.

"The Relationship of the Anaerobic Streptococcus to Puerperal Infections"—Dr. Melvin Stone.

On May 26, the society held its annual joint meeting with the Queens County Bar Association. There was a symposium on "The Lawyer, the Doctor, and the Patient," the purpose of which was to point out the differences arising between the medical and the legal professions in trials where medical testimony is necessary. It was not a debate, but a discussion of the problems confronting the lawyer and the doctor in relation to liability suits.

The speakers were: The Honorable Henry G. Wenzel, Justice of the New York State Supreme Court, moderator; David J. Kaliski, M.D., chairman of the Workmen's Compensation Committee of the Medical Society of the State of New York; Henry Vollmer, Esq., attorney; Walter J. Hess, Esq., president of the Queens County Bar Association.

The Maternal Mortality Committee of the society held its regular meeting on March 27 and April 24 for the discussion and analysis of all maternal deaths in Queens County.

On April 30, the Medical Board of Jamaica Hospital held a lecture on "Chemical Warfare" at the Society building.

The Section on Neurology and Psychiatry held a joint meeting with the Section on Internal Medicine on April 7. The subject was "Emotional Factors in Hypertension," by Dr. Carl Binger. The Section held another meeting on May 22.

The Mental Hygiene Committee has been holding monthly meetings in psychosomatic medicine, concerning some of the problems that the doctor is called upon to meet in general practice.

The Medical Preparedness Committee of the society meets on the average of once a week in its efforts to cooperate with the Office of Procurement and Assignment.—Ezra A. Wolff, M.D., Secretary.

A HUMAN GUINEA PIG TEST—IN AVIATION

A nest of fledglings has just been uncovered for Uncle Sam's air forces. Some 300,000 future Aces between the ages of 17 and 19 will receive a highly technical training annually, as a result of an experiment made in the Navigation Section of Pan American Airways which is training young army air corps cadets at the University of Miami.

A human guinea pig test disclosed that the average young high school graduate can master aerial navigation and meteorology almost as quickly as can the college graduate, if he shows the proper aptitude. Previously, some college education has been considered essential to master such technical skill within the short time prescribed in the army's war preparation program.

To determine the potentiality of high school graduates as aerial navigators, a 17-year-old graduate of Miami High School was chosen to take the navigation and meteorology course in a class of college men being taught by Pan American Airways. The test case graduated from high school with just average honors.

Charles Lunn, director of the Navigation Section which is training both American and British cadets,

foresaw the time when the United States might need to dip into the reservoir of high school graduates to obtain manpower for its growing warplane armada. He appealed to the army and was granted permission to experiment with a high school graduate.

During the first three weeks, the youngster lagged behind his college-graduated classmates, displaying a slow mind in grasping the significance of the work, but upon mastering the fundamental conception of the course, he forged ahead rapidly, making grades as good as the best of them.

Although he received no special instruction, he kept pace with the others and graduated with a rating that would have given him a commission as second lieutenant in the army had he been eligible.

His graduation means that each year some 300,000 other young men of like age and education are potential material for aerial navigation instruction, figuring that of about 600,000 young men graduating from high school, at least half are of the required physical and mental makeup.

Rensselaer County

Dr. George D. Hoffeld of Troy has been assigned to the Providence, Rhode Island, naval recruiting station from the Newport naval training station. He will work with Lieut.-Com. John H. Fay, senior medical officer at the main office in Providence.

Dr. Hoffeld, who has been a surgeon in Troy since 1931, was graduated from the Long Island College of Medicine and did postgraduate work at the Cook County Hospital in Chicago. In 1940 he discovered suprarenal backache disease, and published an article on the subject in the *JOURNAL* in 1940.

He joined the Navy a few months ago.*

"The city of Troy ranks second among second-class cities (50,000 to 100,000 population) of this state in the percentage of children, under five years of age, immunized against diphtheria," Dr. James H. Flynn, Troy health officer, stated on May 7.

Dr. Flynn made the statement as he appealed to parents of the city to have their children immunized against smallpox and diphtheria at the present time.

A bulletin of the New York State Department of Health, dated January 1, 1942, shows that Utica was first in the state, with a rating of 76 per cent, and Troy, was second, with a rating of 71 per cent.*

Rockland County

The regular spring meeting of the county society was held at the Rockland State Hospital, Orangeburg, on May 6.

Dr. John J. Moorhead, of New York City, delivered a most interesting talk on the "Surgical Phases of the Pearl Harbor Attack." He was in Hawaii at the time of the Japanese attack, lecturing to the physicians at the University of Hawaii on traumatic surgery. Not more than five minutes had elapsed after Dr. Moorhead opened his lecture on December 7, when an explosion occurred outside of the auditorium, and the surgeons were immediately summoned to the Army hospital. Dr. Moorhead, a veteran of the First World War, volunteered his services and was restored to active duty for a couple of months with the rank of colonel. The lessons Dr. Moorhead brought back were most instructive and timely.

After adjournment of the meeting, Dr. Russell E. Blaisdell, superintendent of the Rockland State Hospital, had a buffet supper served to the members of the Society and their guests.—*Alexander N. Selman, M.D., Secretary.*

"Dr. William J. Ryan, for twenty years superintendent of the Rockland County Tuberculosis Hospital, died suddenly at that institution on February 2, from coronary thrombosis.

"Dr. Ryan was universally beloved. In addition to his work at the hospital, he established school tuberculosis clinics throughout the county. Shortly after his arrival in the county, he was elected president of the Rockland County Medical Society. He was then advanced to secretary, in which office he served continuously until his death, being the guiding spirit of the organization. "There have been greater men. There have been none better."—*Dean Miltimore, M.D.*

St. Lawrence County

Dr. L. J. Austin, of Kingston, Ontario, gave a lecture on "Military Medicine" to the St. Lawrence county medical society in Ogdensburg on May 7. The lecture, held at the A. Barton Hepburn Hospital, followed a luncheon at the Crescent Hotel.

Dr. Haven Emerson, of New York City, lectured on May 14, and Dr. F. H. McKay, of Montreal, on May 21.

Saratoga County

Dr. William Ordway, of Mt. McGregor, has completed a splendid work in organizing the medical profession of Saratoga County for National Defense. As Chief Emergency Medical Officer of the county, he has established a control center in Saratoga Springs, operating on a twenty-four-hour duty. Fifty First-Aid stations have been designated, and three fully equipped casualty units are functioning. The American Red Cross has furnished supplies on demand and directed the organization of ambulance units.

Captain William Moore, of Saratoga, is an instructor at the Officers School in Carlisle, Pennsylvania.

Dr. James English, of Schuylerville, received a commission as First Lieutenant, and is stationed at Jefferson Barracks, St. Louis.

The June meeting of the county society will be held at Saratoga Lake.—*M. J. Magovern, M.D., Secretary.*

Schenectady County

Dr. Yolande H. Huber, of New York City, addressed the county society on April 7 on "Plastic and Reconstructive Surgery."

Dr. Richard H. Overholt, thoracic surgeon at the New England Deaconess Hospital, Boston, discussed clinical observations and treatment of commonly disguised lung diseases at a meeting of the county society held May 12 at the Glenridge Sanitarium.*

Suffolk County

The May Clinic schedule at the Huntington Hospital included a chest clinic on May 19, an orthopaedic clinic on June 5, tumor diagnostic service on May 12, and a mental hygiene clinic on May 27.

Warren County

Dr. B. J. Singleton was re-elected president of the Glens Falls Hospital Medical Staff at its annual meeting on May 5. Dr. Floyd Palmer was elected vice-president, to succeed Dr. Byron C. Tillotson, of Fort Edward. Dr. William W. Bowen was re-elected secretary-treasurer.*

Westchester County

More than 250 physicians and their guests heard a discussion of the "Kenny Treatment for Infantile Paralysis" at the regular county medical society meeting on March 17, at the New York Hospital, Westchester Division, in White Plains. The speakers were Dr. Wallace H. Cole, of St. Paul, Minnesota, and Dr. Philip M. Stimson, of New York City, who have been inter-

NUMBER 12

Editorial

Immediate Recruitment of Medical Officers

The Army has streamlined its method of commissioning medical officers.

Five thousand physicians are needed at once.

Eleven thousand or more will be needed by December 31, 1942.

If you have not done so, fill out and return your Procurement and Assignment enrollment form and questionnaire. If you have not received one, write immediately to the National Roster of Scientific and Specialized Personnel, 916 G Street, N. W., Washington, D. C., for your forms.

The Surgeon General will not commission a physician unless he is certified as available by the Procurement and Assignment Service.

1. The Surgeon General and the Adjutant General have named teams of two officers and two clerks, who will procure the names of all available physicians who have volunteered from the state chairman for physicians of the Procurement and Assignment Service in your state.

2. These teams will have the authority to make final decisions on the application forms, to procure and make final decisions on the physical findings and to administer the oath of office immediately to those who qualify physically and professionally, who are under the age of 45 and who are to be given the rank of lieutenant or captain.

3. These teams have the authority to initiate the applications and physical examinations and forward the papers with their recommendations direct to the Surgeon General for commission for all physicians

under the age of 45 who might apparently be qualified for rank above that of captain.

4. These teams will have the authority to initiate the applications and physical examinations and to forward to the Surgeon General direct the papers and their recommendations on all physicians 45 to 54, inclusive. The Surgeon General will make the final decisions and commission those for whom there are vacancies in this age group.¹

In order that this streamlined recruitment of medical officers may function speedily, you are urged to contact your state chairman of physicians for Procurement and Assignment Service, Dr. Henry W. Cave, 292 Madison Ave., New York City, at once.

State to him that you want to get into the service right now.

Do this regardless of whether or not you have written to the Washington office of the P. and A. Service or to the Surgeon General or have enrolled on the emergency enrollment form of December, 1941.

If you applied for a commission more than thirty days ago, tell the state chairman you want to see the recruiting board. The Boards are located in New York State at Albany, Binghamton, Buffalo, New York City, Rochester, Syracuse, and Utica (see page 1160 for names of Recruiting Officers and addresses of boards).

This is no leisurely war. And it can't be won by amateurs or sidewalk superintendents. No training or experience in civil life is analogous to that afforded

¹ J.A.M.A. 119: 33 (May 2) 1942.

[Continued from page 1116]

ested in the application of this treatment for infantile paralysis in the United States.

Discussion of the papers was opened by Dr. Don Gudakunst, medical director of the National Foundation for Infantile Paralysis, who resides in White Plains.

Others who took part in the discussion were Dr. George H. Ramsey, county commissioner of health and chairman of the Medical Advisory Committee of the Westchester Chapter of the National Foundation for Infantile Paralysis, through whom the program had been arranged; Dr. Isadore Zadek, of Mount Vernon; Dr. M. Bernard Brahdy, of Mount Vernon; Dr. William B. Snow, consultant in Physical Therapy to the New York Orthopaedic Hospital; Dr. David A. Lubarsky, of White Plains; Dr. Wallace C. Douglass, of New Rochelle; Dr. Milton P. Hunter, of Pleasantville; and Dr. H. M. Herring, of Mount Vernon. Drs. Cole and Stimson closed the discussion.

"The address of Dr. John J. Moorhead, on 'Surgical Lessons from the Pearl Harbor Attack,' at the society's meeting on April 21, provided an impressive climax in a series of remarkably successful scientific meetings presented during the season now closing," says the *Westchester Medical Bulletin*. "More than 325 members of the society were present at this meeting, comprising the largest number ever to attend a meeting of the county medical society. Dr. George C. Adie of New Rochelle, the president, was in the chair, and the speaker was introduced by Dr. E. Leslie Burwell of New Rochelle, who was a comrade-in-arms of Dr. Moorhead in World War days.

"Dr. Moorhead was at his best, which is very good indeed. In cryptic fashion, he described the strange series of coincidences which resulted in his being in Hawaii at the outbreak of war, and the dramatic and tragic events which took place during and after the surprise attack of the Japanese. . . ."

Dr. Homer F. Swift, of the Hospital of the Rockefeller Institute for Medical Research, was the guest speaker at a postgraduate lecture session on May 13, at the New York Hospital, Westchester Division. His subject was "Rheumatic Fever." This program was arranged for the Public Health Committee of the county society by the Council Committee on Public Health of the State Medical Society and was presented through the courtesy of the State Society and the State Department of Health.

Under the auspices of the county society, a demonstration of the operation of a plasma and blood bank was given by the staff of the White Plains Hospital on May 26, under the direction of Dr. J. W. Ehrlich.

Dr. Ehrlich is the author of an article on this subject that was published in the September 1, 1941, issue of the *JOURNAL*.

Wyoming County

Promotion of Dr. Bruno J. Tryka to the rank of captain at Fort McClellan, Alabama, has been announced. Simultaneously, Captain Tryka was named chief of the Alabama Induction Board, says the *Rochester Democrat & Chronicle*, May 11.

Captain Tryka was the first Wyoming County physician to be inducted into the service, leaving last summer.

THE "AMERICAN WAY" PROGRAM

The Medical Society of New Jersey and Kiwanis clubs in the state cooperated in a project that resulted in eighty-four talks being given before 4,000 Kiwanians on the topic "The American Way of Distributing Medical Care."

PATIENCE

Officer (to man pacing the sidewalk at 3 o'clock in the morning): "What are you doing here?"

Gentleman: "I forgot my key, officer, and I'm waiting for my children to come home and let me in."

—*Milwaukee Med. Times*

must be given in four different calendar years, the obvious result will be that graduates after the abbreviated course will be disqualified for licensure unless the standards are reset by amendatory legislation."

The report says that "Within the next few months an attempt will be made to develop a fairly accurate approximation of the number of trained personnel to be secured by this process of speeding the production of physicians and to ascertain whether the number of physicians so trained will be adequate to supply the anticipated needs of the military and civilian population for new graduates during the next few years."

This report is of such significance that we urge careful reading of it on our members. It should be studied in connection with the urgent necessity for the establishment of uniform standards of licensure.

In pointing out that war conditions emphasize the great need for such uniformity, the *Journal* says:

"The results of the state licensing examinations published in this issue of the *Journal* are striking evidence of the lack of uniformity of standards of licensure among the various states. Seven states reported not one failure in their 1941 licensing examinations; indeed, they had not had a failure in the past five years. Twelve additional states have reported failure of less than 1 per cent during the same period. Other states, notably New York, have each year reported a high percentage of failures.

"In New York 21.8 per cent of the gradu-

ates of the New York State medical colleges who tried the New York State licensing examinations failed, while 39.4 per cent of the graduates of other approved medical colleges in the United States who tried these same examinations failed. Of the 145 graduates of New York State medical colleges who tried licensing examinations in other states, 4, or 2.8 per cent, failed

"The lack of uniformity of results in some states is made more obvious by the fact that a candidate is passed if he receives an average of 75 per cent and is not below 50 per cent in any subject. Furthermore, in case of failure in not more than two subjects the applicant may be entitled to another examination in the subjects failed and is considered conditioned and is not reported as a failure.

"Paradoxically, New York, which reported the highest percentage of failures among the graduates of approved medical colleges on its own examinations, issued a greater number of licenses on the basis of credentials without examination than did any other state.

"In spite of this lack of uniformity, the fact is striking that the graduates of the foreign medical schools and the unapproved schools in the United States showed the highest percentage of failures, 59.6 and 46.0, respectively. Six states licensed graduates of unapproved schools during 1941. Four states granted unlimited licenses to practice medicine to graduates of osteopathic schools."

The situation in this state as revealed in the report on licensing examinations in 1941 is, to say the least, paradoxical. There should be an explanation forthcoming.

Immunity Against Pertussis

Whooping cough is the one contagious disease of infancy that remains unsolved. Deaths from measles, scarlet fever, diphtheria, and infantile paralysis—all combined—do not equal the total number of annual deaths from pertussis in babies. Attempts have been made to induce immunity in young infants, but they have all failed. Experimental efforts hitherto have not exempted even laboratory animals, which have been inoculated against whooping cough.

It occurred to Cohen and Scadron¹ that if

the pregnant mother could be immunized actively during the latter part of her pregnancy, the newborn child might have a safeguard against infection by *Bacillus pertussis*. Accordingly, they inoculated expectant mothers with one hundred and twenty to one hundred and fifty billions of a potent whooping cough vaccine. Agglutinins, complement fixings, and protective antibodies that were controlled by mouse protection tests were subjected to studies in both mothers and their babies before and after inoculations. They studied 200 women by this method, and 32 of them and their offspring were subjected to immunologic studies. Every one of the

¹ Cohen, P., and Scadron, S. J.: Paper read before the Section on Pediatrics, Convention of the American Medical Association, June 10, 1942.

by active military duty. For this reason physicians entering the military services must be intensively trained for their new duties. All of this takes time.

It is therefore imperative that recruitment of medical officers shall go forward as rapidly as possible. Sign on now, doctor!

The Physician Population

In view of the ever increasing demands of the military services and expanding industry for competent physicians, information at this time on the increase in the physician population of the United States is timely.

There were 5,681 additions to the medical profession in the United States and its territories and possessions in 1941, the Council on Medical Education and Hospitals of the American Medical Association reports in its fortieth annual compilation of medical licensure and allied statistics, published in the May 9 issue of the *Journal* of the Association. "The number removed by death annually approximates 3,700," the report says. "It would appear that the physician population in 1941 was increased, therefore, by about 1,900. While it cannot be said that all of those licensed are in practice, it may be assumed that the great majority are."

"The greatest number in any one state were added in New York, 993, and 449 in Illinois," the report says. "More than 300 received their first license in California and Pennsylvania. The states of Indiana, Louisiana, Maryland, Minnesota, Missouri, New Jersey, Tennessee, Texas, Virginia, and Wisconsin increased their population of physicians by between 100 and 201. Thirty-one states, the District of Columbia, Alaska, Hawaii, Puerto Rico, and the Virgin Islands added fewer than 100. Of the licentiates constituting additions to the medical profession last year, 5,213 secured their licenses after examination and 468 by endorsement of credentials."

Commenting on this aspect of the annual report on medical licensure, the *Journal* says that "Of these 5,681 newly licensed physicians, 626 were graduates of foreign medical schools, and 226 were graduates of unapproved medical colleges in the United States. During 1941, 4,738 graduates of approved medical colleges were added to the profession in the United States. Accumulated data indicate

that during the past seven years there have been 41,983 new additions to the profession.

"As a result of increases in the number of students admitted and the adoption of an accelerated curriculum by most of the medical colleges, the annual additions to the profession from the medical schools of this country should increase by more than 25 per cent during the next few years."

According to the report, the greatest increase in physician population, according to geographic division, was 1,554 in the Middle Atlantic states. The East North Central group added 1,183, the South Atlantic 622, the West North Central 608, the Pacific group 440, the New England states 418, the West South Central group 415, and the Mountain states 91.

Forty-nine medical schools have adopted an accelerated curriculum, involving both the acceptance of entering students and the graduation of a class every nine months. Eleven have adopted an accelerated curriculum involving the graduation of a class every nine months but will admit an entering class on an annual basis. One school will continue operating on the four quarter plan, admitting new students and graduating a class every quarter. Eight schools have not adopted an accelerated program.

"As has been pointed out," the report says, "there are many difficulties involved in the acceleration of the program, and where a school has failed to adopt such a program in order to maintain satisfactory standards, it is to be commended rather than criticized."

"The acceleration of the training of medical students to the end that graduation will occur following three calendar years of instruction raises questions concerning medical licensure that demand consideration along with a consideration of the merits of the proposal itself."

"The medical practice acts of the several states define the standards that a medical school must maintain in order that graduates may qualify for licensure. If those standards are defined in such a way that courses of study

BACTERIAL FILTRATES IN THE TREATMENT OF CUTANEOUS INFECTIONS

FRANK C. COMBES, M.D., New York City

IN 1924 Alexander Besredka¹ reported for the first time on the use of bacterial filtrates in the prevention and treatment of various infectious processes. He declared that bacterial filtrates, locally applied, inhibit the development of the microorganisms from which the filtrates are prepared, and exert a therapeutic effect by increasing the natural immunity of the skin.

Besredka prepared broth cultures which he filtered after an incubation period of eight days. He then inoculated the sterile filtrate with the original bacterial strain, and re-filtered the culture after a second incubation period of eight days. Besredka called this filtrate the "antivirus." During the preparation of the bacterial filtrates, he noted that the growth of bacteria was less intense in the first filtrate, and that in repeating the process he obtained a product in which no growth occurred. He attributed this lack of growth to the presence of an antivirus, which he believed to be a specific for the organisms from which it had been elaborated. Besredka referred to many clinical reports to show that the bacterial filtrates were being used with considerable success as wet dressings on a variety of local staphylococcic and streptococcic infections.

Subsequent investigators, including Gay and Morrison,² Rivers and Tillett,³ Mallory and Marble,⁴ conclusively demonstrated that the effect of the filtrate was actually an amplification of tissue immunity through stimulation of the clasmatoocytes. The work of Mallory and Marble and that of Toomey and Friedlander⁵ showed that temporary local immunization against staphylococci could also be produced by wet dressings of uninoculated broth. Gay, however, although unable to assert that a specific form of cell protection is involved, came to the conclusion that the use of filtrates of specific microorganisms "give rise to thicker granulation tissue, more clasmatoocytes, and still greater protection than those obtained with broth alone." According to Oesterlin, bacterial filtrates possess infection-resisting qualities that are entirely lacking in broth. Admitting that an occasional

increase in resistance caused by nonspecific filtrates has been found, he insisted, nevertheless, that the protection produced by specific filtrates seems to be more intense and more dependable.

In 1932, Besredka,⁶ while not disavowing his original assertion that the filtrate possesses definite specificity, conceded that its action in some cases might be indirect by increasing the resistance of the cells. He maintained, however, that staphylococcus and streptococcus bacterial filtrates fixed alexin electively and were specific, and prevented the development of the corresponding bacteria.

All investigators, while denying the specificity of the bacterial filtrates and their ability to produce constitutional immunity by transcutaneous absorption, admit that the filtrates are capable of producing local immunity of varying degree.

Besredka's concept of local immunity drew much attention; however, few clinical reports on the therapeutic value of bacterial filtrates have been published in this country. Only recently these filtrates have found a wider application in the treatment of local infections. Boenke⁷ reported on the treatment of a case of erythema induratum with a filtrate of staphylococci, streptococci, and *Bacillus pyocyaneus*. Boyd and Weissberg⁸ successfully applied bacterial filtrates to many cases of varicose and diabetic ulcers that had resisted other medication.

For the past year we have carried on an extensive study to determine the therapeutic value of bacterial filtrates in the treatment of cutaneous infections. To this purpose bacterial filtrates were used in the treatment of various dermatoses occurring in hospitalized patients and in ambulatory patients in private practice. All the patients treated had cutaneous lesions caused by *Staphylococcus albus* and *Staph. aureus*, and by streptococci. In only a few cases were the organisms cultured.

Bacterial filtrates were used in two forms: the filtrate preserved by 0.5 per cent phenol and an ointment containing 12 per cent of the filtrate.* The filtrate was prepared according to the method of Besredka from *Staph. albus*,

From the Department of Dermatology and Syphilology, New York University College of Medicine, and the Third Medical (New York University) Division, Bellevue Hospital, Service of Dr. Frank C. Combes.

* The material for this study (Antipeol Liquid and Antipeol Ointment) was kindly supplied by the Bio-Therapeutic Laboratories, Inc., East Orange, New Jersey.

women showed a high titer of immune bodies, which was transmitted in every instance to the baby. The controls showed few or no immune bodies in the newborn.

All past work on this subject seems to indicate that Cohen and Scadron have been able to produce, finally, a passive immunity against whooping cough in the newborn. They state, naturally, that further studies must be pursued to determine the duration of

this immunity. *The time is too short to evaluate the duration of the protection afforded, but this is being followed up assiduously.*

Their work is to be noted. It represents a new approach in preventive medicine. If our newborn babies can be assured protection against whooping cough for but a few months, a definite lowering of infant mortality will result. It is hoped that this work will be continued and corroborated.

Correspondence

May 13, 1942

The Council
Medical Society of the State of New York
292 Madison Avenue
New York, New York

RE: Introductory No. 2037, No. 2522,
introduced March 18, 1942, by
Mr. Milmoë.

Gentlemen:

In the Supplementary Report No. 2 issued by the Committee on Legislation of the State Medical Society on April 25, 1942, Dr. Joseph S. Lawrence mentioned my name as opposing the Milmoë Grievance bill.

In all fairness and justice, the following are my reasons for opposing this legislation:

"The above bill which is an act to amend the Education Law in relation to the Committee on Grievances, empowered to hear, determine and make recommendations to the Board of Regents in disciplinary proceedings against physicians, seeks to modify the law, by providing that a *unanimous vote of the subcommittee of three is necessary for a finding of guilt. The proposed amendment to Section 1265 of the Education Law is objectionable and inequitable.*

"At present, Section 1265 of the Education Law requires a unanimous vote of the full committee of ten members of the Medical Grievance Committee in order to find a practitioner of medicine guilty of charges after a hearing.

"This provision has long been criticized and properly so, because of the unusual and unwarranted power it places in the hands of one member of the committee, to frustrate the decisions of the nine other members. After the expense incurred and the time spent in lengthy preliminary investigations, authorization of charges, preparation of such charges and hearings thereupon, it seems unjust and inequitable that the determination and convictions of nine men are rendered meaningless by the decision of one member to dissent. The law should be more flexible so as to allow for the sincere and honest differ-

ences of opinion which necessarily arise in the trial of controversial issues without defeating the purpose and intent of the law. Judges in Appellate Courts differ in their reactions to identical sets of facts, but such differences are not permitted to render useless their deliberations and decisions.

"In the legal profession, where courts deal with substantial rights of property or with the freedom of even the lives of men, ultimate action may be by majority decision, viz.: In the Appellate Division of the Supreme Court by a vote of 3 to 2, in the Court of Appeals by a vote of 4 to 3 and in the United States Supreme Court by a vote of 5 to 4.

"Now it is suggested that Section 1265 of the Education Law be amended to require a *unanimous vote of guilt by the subcommittee of three who originally hear the charges.* If there is not a unanimous vote, under the proposed amendment, then the case is dismissed without the knowledge of the full Committee. This, I believe, is too great a power and responsibility for any one member. Thus, the very power to veto the will of the full Committee which now exists in the requirement of the unanimous vote, will still be lodged in one member except that under the proposed amendment, he would be able to exercise this objectionable power by dismissing a case at its inception.

"The Medical, Homeopathic and Osteopathic professions do not seem to trust their prominent members who gratuitously serve on these committees. Therefore, it is proposed that no disciplinary action can be taken against a doctor except by *unanimous vote of the subcommittee*, so that one member of the committee can stand in the way of intelligent action, thereby keeping in the profession an undesirable, unethical, dishonest practitioner. In these enlightened days that condition should not prevail. The medical profession should not be subject to the charge that it is protecting those who violate the Medical Practice Act.

CIVILIAN BLOOD BANKS PLANNED BY LOCAL COMMITTEE

The collection of blood plasma for military use should not obscure the need for a permanent, inexpensive reservoir of whole and processed blood for civilian transfusions. Headed by Dr. Lester J. Unger, the Special Committee on Blood Transfusion of the Medical Society of the County of New York has made an interesting and important contribution to this problem with a plan for the creation of blood banks in large hospitals to supply the requirements of smaller institutions, says *The Journal of the Medical Society of the County of New York* in a recent issue.

To operate a successful blood bank, a hospital must do at least 750 or 1,000 transfusions a year. Otherwise, it alternates between an excessive supply of blood, which goes to waste, and shortage. The plan suggested by the County Society's Special Committee would establish banks at suitably equipped hospitals from which blood or plasma could be drawn, and in which it would be deposited, according to need. One of the participating institutions would be designated as a central office where all available supplies would be registered, for the information of hospitals without compatible blood at any particular time.

Basic charges would be somewhat lower than current rates for private patients. Ward and semiprivate patients would benefit more materially. As increased volume permitted, charges would be reduced.

A noteworthy feature of the plan suggested by Dr. Unger's committee is the negligible capital investment required—about fifty dollars, plus the cost of a refrigerator for each participating hospital. To be appreciated fully, this figure must be compared with the \$25,000 quoted by the Blood Transfusion Betterment Association, and the \$75,000 by a commercial organization, as the initial cost of similar projects.

With the impetus given to the collection and storage of blood and plasma by the war, there is danger that this field may be taken over by lay business interests unless physicians and hospitals act first. Commercial operation would not be in the best interests of the public. In view of its low initial cost and administrative simplicity, the plan suggested by the Special Committee on Blood Transfusion of the Medical Society of the County of New York merits serious consideration.

A MESSAGE FROM LENOX HILL HOSPITAL TO ALL NURSES

The following is a comparison of the earnings of General Duty and Special Nurses at today's rates:

<i>General Duty Nurses</i>	
Salary for 12 mos. at \$75.00.....	\$ 900.00
Allowance for living out.....	300.00
3 meals per day—11 mos.	396.00
(approx. value \$1.20 per day)	
Value of laundry at \$5.00 mo.	60.00
	<hr/>
	\$1,656.00

Provided also at no cost to the nurse,
1 mo. vacation
2 weeks' sick leave
Compensation coverage in the event of injury or infectious disease.

<i>Special Duty Nurses</i>	
11 mos. (6-day week).....	\$1,440.00
(this is optimum, not average)	
Value of 2 meals per day for 288 days at \$0.80.....	230.40
	<hr/>
	\$1,670.40

No provision for salary during vacation. No time off for holidays. No sick leave allowance. No compensation coverage.

Please note that the above calculation is on 288 days of work for each type of nurse.

Only a few specials can do this. The average earnings in our hospital are a little over \$1000 or about \$400 less than shown in the table; and we do better than most hospitals.

Even if the hospitals approve an increase of \$1.00 per day for Special Duty nursing, the average earnings will be \$100.00 less per year than for General Duty Nursing, and the advantages of General Duty Nursing will still be lacking.

These are war times. Special Nursing is a luxury. Our Country and our Hospitals need nurses. The decision is up to you.—Printed in *Bureau-Grams*, May, 1942

It is recorded that a famous Danish surgeon offered to furnish a volume of his mistakes to the International Technical Surgeons. He thought

his errors would be more instructive than a report of his successful procedures.—*Sims's Connotations*, reprinted from *Medical Record*

aureus, and citreus, *Streptococcus viridans*, pyogenes, and haemolyticus, and *B. pyocyaneus*. The filtrate was diluted with three to five parts of physiologic saline solution. A report of the results follows.

Carbuncle.—Fifteen patients with carbuncles were treated with uniformly good results. The most satisfactory effects seemed to follow the application of the ointment during the stage of congestion, changing to the filtrate during the period of necrosis. The essential features in all instances were a lessening of the pain and the rapid onset of suppuration, often within twenty-four hours. There did not appear to be any curtailment of the period of involution, although liquefaction and discharge from the lesions were more profuse than in cases in which the filtrate was not used. The local use of the filtrate did not prevent the development of metastatic lesions on other parts of the body. In no instance was it necessary to incise or excise a lesion.

Furuncle.—Twenty-six patients with furuncles, of from one to several lesions, were treated. The method was similar to that followed in treating carbuncles, but in many cases the ointment was used exclusively. The results were approximately identical. In no instance was it necessary to incise a lesion, although in several cases openings were bored in the apex, with pure liquefied phenol on an applicator. There was an acceleration of the healing process after the expulsion of the necrotic slough. Here again the filtrate did not prevent metastatic lesions, although in one patient, with a multiple furunculosis of several months' duration that was confined to the leg, the process was checked and cured by the application of the ointment twice daily to the entire area.

Hydradenitis Axillaris.—Five patients with recurrent abscesses in one or both axillas were treated with the ointment. Results were good in 3 patients; one patient who had experienced recurring lesions in one axilla was permanently relieved within three weeks. During this time she developed a lesion in the other axilla. This lesion also responded promptly to dressings moistened with the ointment. One patient, a man, with involvement of the perineal region, was also benefited by application of the ointment.

Furuncle of the External Auditory Canal.—Two cases were treated by means of gauze wicks placed in the canal, the patient keeping them moist with the filtrate. In both cases there was prompt relief from pain. In one case it was necessary to incise the lesion. This patient also had a seborrheic dermatitis involving the canal, which was improved by the ointment but recurred when its use was discontinued.

Furuncle of the Nares.—Furuncles in this location are potentially dangerous and necessitate conservative therapy. One patient with such a lesion was treated with the ointment and recovered rapidly. He also received intracutaneous injections of sterile milk protein, which may have contributed to the rapid liquefaction of the lesion.

Sycosis Vulgaris.—Six cases were treated, none of which had responded favorably to other measures. None of them was helped by either the ointment or the filtrate.

Ulcus Cruris.—Two ulcers of the leg in dia-

betics that were recalcitrant to various remedies responded to application of the ointment. One of the patients was confined to bed, which undoubtedly aided in his recovery. Fourteen patients with simple ulcers of the leg associated with varicose veins were helped by application of both ointment and filtrate. Three leg ulcers of unknown cause were unimproved. One leg ulcer of two years' duration from which *Staph. aureus* and *Str. haemolyticus* were cultured responded favorably to the treatment. One patient with three ulcers of the arm following bites by humans was unimproved following treatment with the ointment.

Perifolliculitis Abscedens et Suffodiens.—One patient was treated without benefit.

Staphylococchia.—One patient with a severe *Staph. albus* infection of several months' duration involving the scalp, the bearded region of the face, the nose, the eyebrows, and the eyelids was unaffected by either the ointment or the filtrate.

Infectious Eczematoid Dermatitis.—Five cases of infectious eczematoid dermatitis were treated; 4 improved; one was unimproved.

Varicose Eczema.—Eleven patients with varicose eczema were treated with the filtrate. It was efficacious in eliminating secondary infections and crusting of the lesions. While none of these patients was cured, all showed definite improvement.

Tabetic Ulcers.—One tabetic ulcer was treated with objective improvement following the application of a wet compress of the diluted filtrate. Later the lesion was packed with the ointment, but no further benefit was noticed.

Impetigo Contagiosa.—Eight patients with impetigo were treated with the ointment. Patients were instructed to cleanse the lesions twice daily with soap and water, to remove the crusts and to apply the ointment every three or four hours. The results were better than those obtained by the use of ammoniated mercury ointment, the length of disability averaging about ten days. Two patients recovered after three days.

Acne Vulgaris.—Five patients with acne vulgaris were treated with the ointment. None of them improved. Eleven cases of pustular acne were treated in the same way. Eight of these showed improvement, with disappearance of the pustular lesions; the others showed no change.

Blepharitis.—Two patients with chronic blepharitis marginalis were treated with the ointment. Both improved but later relapsed. This failure may be explained on the basis that both patients had a seborrheic dermatitis of the face and scalp.

Conclusions

1. Notwithstanding their lack of specificity, bacterial filtrates exert a beneficial effect on staphylococcal and streptococcal infections of the skin, especially carbuncle, furuncle, and impetigo.

2. The essential features of therapy with bacterial filtrates are prompt relief from pain, rapid onset of suppuration, and acceleration of the healing process.

3. Its effects are entirely local and there is

FIG. 1. Experimental dehydration in the cat: illustrating increase in blood density before changes in salt concentration.

of dehydration; and (5) they foretell the ultimate fall in blood pressure. In other words, the shift of fluid from blood to tissues heralds the approach of shock, and by being forewarned one is forearmed.

In following a case of shock, the sensitivity of these tests can differentiate between shock due to trauma or dehydration and shock due to hemorrhage. Thus, internal hemorrhage can be detected before fall in blood pressure or before clinical manifestations of blood loss.

The four tests which we make in cases of shock, as well as in the control of fluid therapy, are: specific gravity of *peripheral blood*; cell volume as determined by the hematocrit on venous blood; specific gravity of plasma; and estimation of total plasma proteins (Fig. 3). These tests can be made within fifteen minutes' time and give objective evidence as to whether more fluid should be given or whether fluid therapy should be stopped. They also help to decide whether blood, salt, glucose, or plasma should be used.

Case Report

A man, aged 26, was brought to the Presbyterian Hospital ten minutes after his motorcycle had crashed into a tree. He was treated for shock on admission. In a subsequent intravenous pyelogram, the left kidney outline could not be seen. He was treated for four days conservatively, during which time his fluids were pushed.

The dilution of the blood in this case is well illustrated by the decrease in cell volume (hematocrit) and in total plasma proteins (Fig. 4). Yet despite adequate excretion by the other kidney (as judged by the output) and the large administration of fluids, the patient's circulating system was being flooded by the potassium liberated from injured tissue. Had he been operated upon during this period of hyperpotassemia, the outcome might have

Fig. 2. Barbour and Hamilton apparatus for measuring the specific gravity of body fluids.

been different. These measurements reveal the wisdom of conservative therapy during the first few days in dealing with traumatic rupture of the kidney.

BLOOD STUDIES IN SHOCK AS A GUIDE TO THERAPY

The Defense Mechanism of the Kidney

JOHN SCUDDER, M.D., New York City

UROLOGISTS may be interested in the fact that Roy's⁹ work on the kidney paved the way for the new conception of shock. In 1884, Roy proved that following nervous stimuli kidney volume decreased, as measured by a Masso instrument. This is due to a contraction of the renal blood vessels. Simply stated, blood vessels narrow following harmful stimuli.

Of what significance is this discovery?

If one should ask an engineer what would happen to the volume flow of water if a two-inch pipe were to replace a four-inch pipe, he would immediately answer that one would get only one-sixteenth as much water, if all the other factors were held constant. This same Poiseuille's law holds good for blood flow. If such organs as the brain, heart, or kidneys were to receive only one-sixteenth of the usual amount of blood because of vasoconstriction, it would not take long for serious injury, or perhaps irreversible damage, to occur.

Roy was also curious as to what would relax these constricted vessels. He saw that ordinary saline introduced into the circulating system would do so. You have observed this phenomenon at operations. When the saline is started, there always seems to be more oozing in the operative field, and the cut arterioles appear to squirt more vigorously.

Feltz and Ritter⁴ in 1881, working on experimental uremia in dogs, saw an increase in potassium in both the blood and the tissues. In these states, extra potassium salts hastened the onset of death. Recently, these original observations of Feltz and Ritter have been strengthened and confirmed through electrocardiographic data in relation to experimental uremia in dogs.¹⁷ The effect of potassium upon the electrocardiogram in man^{6,11} and in animal^{3,5,12,13,14,15,16} have been noted.

It has been established beyond reasonable doubt that alterations in salt concentrations are associated with the syndrome of shock.^{10,19}

From the Surgical Pathology Laboratory of the College of Physicians and Surgeons, Columbia University, New York City.

Read by invitation at the Annual Meeting by the Medical Society of the State of New York, Buffalo, April 30, 1941.

Of the various cations, the potassium ion shows the greatest change. This is because, like the rabbit, monkey, and pig, man is a potassium animal. Following injury, potassium escapes from damaged tissue and must be excreted. The kidneys and the adrenal cortex stand first in the maintenance of the normal distribution of water and salts. It is for this reason that good renal function is of paramount importance in the control of shock. Should this excretory mechanism fail, some of the potassium is excreted in the stools, saliva, and sweat. As an emergency mechanism, vomiting probably rids the body of excessive accumulation faster than any other mechanism.

Do we depend upon sodium and potassium analyses in the management of a case of shock? We do not, for the simple reason that such analyses take many hours, at a time when we need measurements which take only a few minutes.

There are, however, certain tests that are more reliable than either potassium or sodium analyses. These tests are also of more value because they anticipate by hours, and in certain instances by days, the ultimate changes in the salt concentrations (Fig. 1). Robert Boyle² first made use of them in 1684. Boyle was a physicist and was curious about weights of things. He measured the specific gravity of both blood and serum, and found it in each case to be greater than that of water, and to differ in various diseases. This work was substantiated by Jurin⁷ in 1719. During the early half of the nineteenth century, the cholera epidemics which swept Europe and England afforded an opportunity to O'Shaughnessy⁸ in England and to Wittstock¹⁸ in Germany to determine that both blood and serum lost water as judged by the increase in their weights. Today we have the modified Barbour and Hamilton¹ apparatus for the determination of density of body fluids (Fig. 2).

Other reasons why we rely on specific gravity tests of blood and of plasma in the syndrome of shock are: (1) they are easily done; (2) they are readily mastered; (3) they are reproducible; (4) they are twenty-five times as delicate as the red blood count in the assay

FIG. 1. Experimental dehydration in the cat: illustrating increase in blood density before changes in salt concentration.

of dehydration; and (5) they foretell the ultimate fall in blood pressure. In other words, the shift of fluid from blood to tissues heralds the approach of shock, and by being forewarned one is forearmed.

In following a case of shock, the sensitivity of these tests can differentiate between shock due to trauma or dehydration and shock due to hemorrhage. Thus, internal hemorrhage can be detected before fall in blood pressure or before clinical manifestations of blood loss.

The four tests which we make in cases of shock, as well as in the control of fluid therapy, are: specific gravity of peripheral blood; cell volume as determined by the hematocrit on venous blood; specific gravity of plasma; and estimation of total plasma proteins (Fig. 3). These tests can be made within fifteen minutes' time and give objective evidence as to whether more fluid should be given or whether fluid therapy should be stopped. They also help to decide whether blood, salt, glucose, or plasma should be used.

Discussion

Dr. Paul W. Searles, *Buffalo, New York*—In the impressive and thorough method of following a case of shock outlined by Dr. Scudder, the comparative minute-to-minute check-up of all the properties of blood with which we are concerned in shock gives us a clear-cut plan of treatment.

The actual determination of the blood and plasma specific gravities and of the cell volume is quite simple to do, but the correct valuation of results can only be obtained by a frequent use of the method.

I have not followed specific gravities in patients before or during operation. This would mean that about 10 per cent of the cases coming to surgery would have specific gravity determinations immediately before operation and during operation. I think that specific gravity determination would be worthwhile in cases that are poor risks or are having operations in which shock is most likely to occur. My method at present is to set up an intravenous drip in this type of case. Blood or plasma is often administered before any fall in blood pressure or marked elevation in pulse occurs, merely on the basis that shock is anticipated.

I have followed the specific gravity of the blood and the plasma in several burn cases. I

was able to keep one case with a 75 per cent burn of the entire body alive for one month by the use of plasma. The amount of plasma and other intravenous therapy to be administered was based on specific gravity determinations.

The determination of the cell volume is also a simple procedure and gives an immediate index to the concentration of red cells. The red count and hemoglobin can be roughly determined from this procedure. Roughly, a hemoglobin over 130 per cent, due to loss of fluids into the tissues, forewarns of a fatal ending. Likewise a hemoglobin below 25 per cent caused by hemorrhage is considered fatal.

I have been impressed by the large dose of adrenal cortex given intravenously by Dr. Scudder. It is always rather difficult for me to conclude whether the adrenal cortex is the factor which is improving the patient or whether it is the plasma. I am sure that my dose of adrenal cortex has not been sufficient.

Dr. W. C. Eikner, *Clifton Springs, New York*—We are particularly grateful to Dr. Scudder for his excellent presentation regarding the changes in the blood and tissues of the body predisposing to the condition that we speak of as shock. Dr. Scudder has been a pioneer in this field of investigation, having first become interested in it in dealing with Asiatic cholera while serving as a medical missionary in India. His recently published monograph on the subject bears evidence of his years of earnest endeavor, not only at the bedside, but in the experimental laboratory.

While I have had no personal experience with the details of the laboratory tests involved in studying the blood in shock, I am sure that all of us here are perfectly familiar with the condition which we call shock. To my mind there has been no better description of the clinical picture of shock given than that included in the definition made by W. B. Cannon, which is as follows:

"Shock is a generalized bodily state, which occurs after severe injury, and which is characterized by a low venous pressure, a low or falling

arterial pressure, a rapid, thready pulse, a diminished blood volume, a normal or increased erythrocyte count and hemoglobin percentage in peripheral blood, a leukocytosis, an increased blood nitrogen, a reduced blood alkali, a lowered metabolism, a subnormal temperature, a cold skin moist with sweat, a pallid or grayish or slightly cyanotic appearance; also by thirst, by shallow and rapid respirations, often by vomiting and restlessness, by anxiety changing usually to mental dullness, and by lessened sensitivity."

This, of course, is the classical picture of acute surgical shock, and one in which we need no particular laboratory studies to aid us in recognition. The important point, however, for us to remember as regards Dr. Scudder's presentation, is that by the use of the hematocrit, serum protein studies, etc., on patients in our wards, we shall be able to predict impending shock long before its actual occurrence. By having this information at hand, and noting changes in the blood serum indicative of impending shock, we are placed in a much better position in treating the patient. Being forewarned is certainly being forearmed.

Acute surgical shock following trauma, such as in automobile and industrial accidents, etc., still is our most difficult problem. Over this we have no particular control except as regards the prognosis and regulation of the treatment. In other cases, however, it would seem advisable to have all of the information at hand, so that the patients can better be prepared for the procedures they have to undergo.

A more simple definition is that shock is a deficiency in the circulating blood or fluids. As Dr. Scudder has already pointed out, there are many factors which influence this deficiency. In the treatment of a shock patient, measures must be taken to combat this deficiency. By and large the most efficacious single remedy is blood transfusion. Intravenous administration of isotonic or hypertonic saline and glucose solution is very valuable, but it is to be remembered that the effect lasts for a short period of time only. Extracts of adrenal cortex have also proved to be very beneficial, but here also the effect is short-lived and repeated doses are always necessary.

While blood transfusion has proved to be our most valuable aid in the treatment of shock, one drawback has been the difficulty which we have all had in securing a proper donor, particularly in the middle of the night. This situation has been

solved by the institution of blood banks in the larger medical centers, but in smaller hospitals, where the frequency of blood transfusion has been much less than in the larger centers, the preservation of whole blood has been somewhat of a problem. It has been our practice to store citrated blood in a refrigerator, and we have found that this can be done satisfactorily for a period of at least two weeks. We try in this way to secure enough blood ahead of time to carry us through any emergency during or following operations, etc. Recently Barton has described a simplified method of satisfactorily preserving citrated blood in 2.5 per cent dextrose for a period of forty-six days. Now, with the advent of blood plasma, it seems that most of our difficulties will have been solved, as it should soon be practical for even the smaller hospitals to have a supply of this on hand.

It would seem to be much more practical and simpler to operate a plasma bank than a blood bank. Harper, Osterberg, Priestley, and Seldom recently described the method used at the Mayo Clinic for the preparation of dried human plasma. This, of course, gives us the ideal solution to the problem of treatment of shock. Dried human blood plasma can be kept sterile and free from deterioration for an indefinite period of time. It is, therefore, always available, and when needed can be given almost on a moment's notice by the addition of sterile distilled water. An additional advantage of plasma over whole blood is that it can be given in concentrated form or not, according to the fluid demands of the patient, and that reactions following its administration are relatively few and mild as compared with those following blood transfusion. The preparation of fluid plasma requires very little additional equipment beyond that ordinarily found in a clinical laboratory, while the preparation of dried plasma is still a tedious, time-consuming task.

It has been recently shown that deficiencies in nitrogen metabolism requirements can be met not only by the addition of protein, but by the intravenous administration of amino acids. Elman and Weiner, and more recently Altshuler, Hensel, and Sahyun have developed methods by which amino acid mixtures can be prepared by the acid hydrolysis of casein. This method of intravenous alimentation, as they call it, is perhaps of more value in cases showing definite symptoms of protein deficiency, such as edema, etc.

When novocaine first came into use, a local dentist in a nearby town tried it out as an experiment. He injected the drug in the jaw of his patient, an elderly man, and then asked him how he felt. There was no answer. The dentist waited a minute and asked, "How do you feel

now?" Still no answer. Nervous, the dentist grabbed a glass of ice water and threw it in the patient's face to revive him. The man jumped up and yelled, "Good Heavens, what ails you? I'm all right. I'm just hard of hearing."

Ill. Med. J.

RETENTION OF THE SPHINCTER IN THE RADICAL OPERATION FOR CARCINOMA OF THE RECTUM AND RECTOSIGMOID

ABRAHAM O. WILENSKY, M.D., New York City

THIS paper purposes emphasis upon resection of the rectum or rectosigmoid in continuity with retention of the sphincter, no matter what the special type and method of approach may be, and with special reference to operability, feasibility, healing of the resulting wound, mechanical results, and permanent results with reference to recurrence and metastases.

Many of the standard forms of operation include a permanent colostomy. To many patients this is not voluntarily acceptable if there is any other choice; they accept it as imperative in the fear of contemplated consequences, and urged on by assurances of livability, etc. But it is my conviction that many times there is a good deal of unnecessary ruthlessness in the sacrifice of the sphincter. This belief seems to be well supported by the following essential facts.

Anatomic Considerations

Embryologically, the anal canal is to be sharply distinguished from the rectum proper; continuity of the bowel at the point of junction is due to prenatal fusion.

Histologic Data

In this part of the large bowel, the presence of squamous cell epithelium in a neoplasm indicates an origin from the anal canal; this type is, however, rare. Nevertheless its presence indicates the clinical likelihood that the direction of spread of the growth is caudad and forward along the perineum; that enlargement of the lymphatic glands is to be looked for in the groins; and therapeutic necessity for dissection toward the anus with removal of the sphincter.

Similarly, the presence of columnar cells and adenoid structure in a neoplasm of this part of the bowel indicates an origin in the rectum proper. This is the common histologic type. It indicates that the spread of the growth is away from the sphincter and toward the mesorectal lymphatics and glands upward toward the abdominal lymph glands. Therapeutically, other things being equal, it permits retention of the sphincter when this is technically feasible.

Forms of malignant adenoma and of papillary carcinoma usually arise from the rectum

proper. While they are histologically malignant, they very often run a very benign clinical course and the extensive dissection required in other forms of carcinoma in this part of the bowel is often not necessary. It has been my experience that local resections done for this type of tumor are as successful both immediately and permanently as the more extensive types of operation. And in any event, in my experience, it has always been possible to conserve the sphincter.

The lymphatic plexus of the anal canal and rectum proper is distinct at first, but fusion occurs later. The lymphatic spread of either segment occurs as indicated in the previous paragraph, and in clinical practice this distinction prevails, except in those instances in which the neoplastic growth involves both sides of the embryologic line of the anorectal junction; in the latter case the spread may occur in either or both ways. Bilateral spread is, however, clinically a relatively rare phenomenon. The histologic differentiation is recognizable in preoperative biopsy specimens.

I agree with Gordon-Watson⁸ that, practically speaking, lymphatic spread does not occur generally until the growth has penetrated through the bowel wall.

Clinical Considerations

Epithelial malignancies of the anus and rectum are of relatively slow growth and, while inflammatory lymph node enlargement is common, neoplastic metastases occur relatively late. This is exemplified in the series of cases reported by Larson,¹¹ and by Harding and Hankins,¹⁰ and the corresponding greater operability is shown in the series of Adams,¹ of Crafoord,⁴ and of the Mayo Clinic.¹³ Lymph node metastases militate against a five-year survival, no matter how extensive the operation is made. Venous metastasis only rarely precedes lymphatic spread and correspondingly contributes to the good results in the cases operated upon early.

Biopsies

Preoperative biopsies are not very reliable for the purposes of prognosis. A somewhat better opinion can be derived from the study of the operatively removed specimen.

Preoperative estimations of the prognosis

according to Brody's method are available in the preoperative biopsy. Duke's method is possible only after removal of the tumor proper. It gives a better picture than Brody's method. No prognosis can be made during the operation from the gross appearances available then of the primary tumor, and the impossibility of distinguishing purely inflammatory from neoplastic glands (60-70 per cent) only adds to the difficulty.

Technical Considerations

Radical Operability.—The radical operation is technically possible when there are not too many adhesions to neighboring viscera, when the tumor has not grown into the pelvic wall, when adjacent viscera are not too extensively involved, when lymph node metastasis is not too extensive, and when distant metastases are not present in the abdominal or other viscera. For the purpose of conserving the sphincter, it is not necessary to give up a single item of radicality in performing the operation. One can remove the entire malignancy with all of its lymphatics and all anatomically associated lymph glands which show the slightest evidence of enlargement; one can include a wide dissection and excision of any suspicious tissue, if the tumor has already perforated the bowel wall; and, if necessary, one can also include the removal of any neighboring organ (uterus, prostate, etc.), if it should seem to be involved by extension of the growth.

The size of the tumor bears no relation (1) to the lymph node enlargement, (2) to the presence of metastases, (3) to the operability of the growth, (4) to the feasibility of its removal, and (5) to the possibility of retention of the sphincter. The size of the tumor is usually of no significance technically, and in any event the tumor is usually relatively and actually small. Its relative position in the rectum or rectosigmoid is not very important.

General factors, such as the general condition of the patient, often only serve to delay performance of the radical operation until such time as the condition is satisfactory.

It seems unnecessary to add that the radicality of any operation is in direct proportion to the earliness of the diagnosis and of the operation. A very important physical factor is obesity: the operative procedure is much more difficult, and the incidence of infection is greater and of much more serious nature when it occurs. This can be an almost insurmountable obstacle to the performance of the operation, to the subsequent recovery of the

patient, and to the healing of the wound.

The success of the operation in this type of major surgery is always in direct relation to the skill and experience of the operator and the helpfulness and teamwork of the assistants. Good postoperative care is of equal importance, and depends to a large extent upon the facilities of the hospital and the faithful care and attention of the nursing staff.

Conservation of the Sphincter.—Retention of the sphincter is possible whenever a radical operation is possible—when the lower border of the malignancy is at least 3 inches from the anal margin—and depends upon the presence of a long, mobile, unscarred sigmoid and mesosigmoid.

Blood supply at the line of junction after resection of the tumor-bearing portion depends upon the point of ligation of the superior hemorrhoidal artery; and, although a high ligation is frequently necessary, this should and can be tempered by the necessities of the occasion and the will not to be too ruthless when the occasion does not demand it. If there has been judicious arrangement of the lines of section, a relatively good blood supply can frequently be retained and the amount of marginal necrosis can be limited. Commonly a fecal fistula forms; but this should be no more deterrent to the determination to retain the sphincter than it is or would be in a resection of the sigmoid with end-to-end suture. Occasionally, too, the effort is rewarded by a healing with so little marginal necrosis that the fecal fistula is negligible or entirely absent.

Resection of the Rectum in Continuity.—Resection of the rectum in continuity with retention of the sphincter undoubtedly creates a greater technical problem than total extirpation of the rectum. Two difficulties have previously repeatedly barred a wider willingness to conserve the sphincter in suitable cases. The first is the difficulty of securing primary healing between the anal and sigmoid stumps. But this is actually no greater than in similar resections of the sigmoid proper with end-to-end suture and there should be no differentiation on this score. The second difficulty has been infection. But modern chemotherapy (a combination of anti-gas serum and drugs of the sulfonamide group used before operation, locally in the wound, and immediately thereafter) has made this risk relatively small.

At the present writing, one may not in this kind of major surgery expect the smoothness of convalescence and healing usually obtained in other types of major surgery which carry

the possibilities of primary suture and healing. But the reward in personal satisfaction and in the gratefulness of the patient is so great as to make the effort very much worthwhile.

Methods of Approach.—The method of approach for the performance of the radical operation does not materially alter the possibility of doing a resection in continuity and retaining the sphincter. The latter may be combined with any of the types of combined abdominoperineal or abdominosacral approach and technic as well as with purely posterior types of operation via the sacral or perineal route. In the light of our present knowledge of the spread of the disease, the type of operative approach should depend on whether the growth is entirely below the peritoneum, above and below, or entirely above, as well as on whether the disease is still local or has spread to the lymphatic channels.

Local Resection.—In general, it may be stated that in about half the cases that may be cured by surgery, the disease can be successfully eradicated equally as well by local excision as by total proctectomy. This should stimulate surgeons to consider a modified radical excision when conditions appear favorable. One very remarkable case, out of a number of similar cases in my own experience, is the following. In 1928, a small ulcerating carcinoma was removed by a local resection, which did not include the entire circumference of the bowel, through a sacral approach. At the present writing (thirteen-year follow-up) the patient is perfectly well in every sense of the word.

Posterior Operations.—Conservative, sufficiently radical resection of the rectum in continuity, with immediate end-to-end direct anastomosis, can be carried out from below. The method was used by Grey-Turner with considerable success in 1935, and by Wood and Wilkie earlier.¹⁵ The various steps of the operation include incision along the left border of the sacrum wall down below the coccyx, with excision of the coccyx and, if necessary, the lower segment of the sacrum; sufficient successive liberation of the posterior, lateral, and anterior aspects of the rectum with as much of its neighboring soft tissues as possible, including the rectal fatty capsule, mesorectum, and glands well into undoubtedly healthy tissue. Commonly, extension of the tumor makes opening of the peritoneal cavity necessary, which facilitates removal of the highly located retrorectal lymph nodes. The tumor-bearing portion of the rectum is sectioned with

the thermocautery between clamps and the proximal extremity is sutured to the anal stump in the orthodox manner.

One refinement of technic, which I have found has added to the success of healing by immediate union, has been a three-layer suture: one for the mucosa, one for the mesial fibrous and muscular layer, and one for whatever peritoneal layer is available plus the rectal capsule.

In very favorable cases, especially in women with a justo major type of pelvis and with an extraordinarily wide interval between the two tuberosities of the ischia, it is possible to avoid resection of the sacrum and sometimes even of the coccyx in removing these growths from below. This is the perineal type of operation. It carries the added advantage that the immediate mortality of the operation is less, that the time of convalescence and healing is much shortened, and that all the inconvenience, pain, danger of secondary hemorrhage, etc., inherent in a wound containing infected bone are eliminated.

All growths below the peritoneum that are reasonably early and mobile should be thus removed by the perineal or sacral method rather than by a combined operation, and whenever feasible with immediate anastomosis. Those that are partly above and partly below can, in many instances, be dealt with in the same way, provided that they are not too far advanced.

Combined Operations.—For the latter type of case, however, and for all operable cases in which the evidence points to advanced disease, with the exception of those growths above the reflection which can be dealt with radically by Hartmann's operation, the combined abdominoperineal or abdominosacral procedure is indicated. This permits the preliminary examination of the abdominal viscera and the determination of the extent of upward spread which is essential for this operation.

I am personally not in favor of reversing this procedure into a perineo-abdominal or sacro-abdominal operation. In my opinion, this is a technical error; it increases the technical difficulties and the risks of infection. There is distinctly more danger in operations begun by the sacral method which must be concluded by another method, necessitating moving the patient several times. Such interventions have an excessively high mortality and should be avoided. If one decides to remove a carcinoma of the rectum through a sacral or perineal approach, there should be

more than reasonable certainty that the operation can be completed by this method.

The immediate success or failure of the various methods of combined operation, the possibility of sufficiently and radically mobilizing the tumor-bearing portion of the bowel during the abdominal part of the operation so that a resection in continuity, with immediate end-to-end suture of the opposing stumps, can be adequately and safely done through the second step, or sacroperineal part of the operation, depend on the same physical factors as when the abdominal part of the operation is eliminated, i.e., adequate mobilization, a long mobile sigmoid, absence of sigmoiditis and mesosigmoiditis, adequate blood supply, skill and experience on the part of the operator. As experience accumulates, the possibility of retaining the sphincter increases without enlarging any immediate or future risk of mortality or recurrence.

Multiple-Stage Operations.—Some surgeons prefer a two-stage operation for the combined type of operation so as to establish a colostomy in advance of the excision. However, it must be said that the presence of a colostomy adds to the risk of infection during the second stage. The technical difficulties during the second stage are intensified by the adhesions following division of the colon during the primary operation. Frequently, and most important, whatever is gained by the so-called safety of multiple-stage operations is lost in the increased danger of the second or subsequent stage. In the absence of obstruction, I have had better results with a primary one-stage operation, and I reserve two- or multiple-stage operations for the obstructive type of case.

"Drawing Through" Operation.—In past years a method was proposed in which the sphincter is retained by drawing the upper segment through the stump of the anus. A very mobile upper segment is necessary for this operation. Of the two "drawing through" methods devised (Mandl and Goetze,¹² Hochenegg), the latter is best. The drawing through is done through the lower segment still retaining its mucosa intact; or a secondary drawing-through operation is done after the sphincter is divided in one plane and the entire anal stump is denuded of its mucosa.

The two methods indicated above are designed for performance through a posterior approach. It is, however, possible to make use of this technic in a combined abdominoperineal or abdominosacral operation in which the drawing-through part of the procedure is

done in the second step of the operation through the posterior incision.

The drawing-through operation is not as successful as the end-to-end suture, in my experience and in the experience of other men which I have been permitted to observe. Secondary abscesses are common; and because these are often dangerously difficult to drain properly, the operation is usually a technical failure.

Case Reports

Case 1.—F. S., a 46-year-old woman with an adenoma malignum, grade 1, of the rectum: a local excision was done through a posterior Kraske type of approach, in March, 1937. There was satisfactory healing and there is no evidence of any recurrence up to the present (four-year follow-up).

Case 2.—A. K., a 50-year-old man with an adenocarcinoma of the rectum beginning as a papillary malignancy: a local excision was done through a posterior Kraske type of approach, in October, 1925. At the end of a ten-year follow-up, there was no evidence of recurrence.

Case 3.—In a 50-year-old man, B. B., a resection of the sigmoid was done in March, 1926, a local resection of the rectum through a Kraske approach in April, 1928, and an ileocecal resection in January, 1929. In each case an adenocarcinoma of the bowel was present without involvement of any lymph nodes. Clinically each of these could be interpreted as being unrelated to the others, except that in this subject there must have been a tendency to malignant degeneration in the bowel, possibly on a papillary basis. In January, 1941 (twelve-year follow-up) this man was perfectly well without any sign of recurrence.

Case 4.—H. A., a 35-year-old woman, had an adenoma malignum, grade 1, for which a resection in continuity of the rectum was done through a Kraske type of posterior approach, in December, 1935. Healing of the entire wound was complete within three weeks. In January, 1941 (five-year follow-up) she is perfectly well with no symptom or sign of recurrence. This is one of the best immediate and permanent results I have had.

Case 5.—J. S., a 60-year-old woman, had an adenocarcinoma of the ampullary portion of the rectum upon a papillary base. A resection of the rectum with immediate suture was done in March, 1937. A small residual fistula was successfully closed by a plastic procedure about eight months later. At the present writing (four-year follow-up), the patient is perfectly well, with no evidence of any recurrence.

Case 6.—W. K., a 45-year-old man, had an infiltrating type of adenocarcinoma of the rectum with no involvement of the lymph nodes. A combined abdominosacral operation, with resection of the rectum in continuity and immediate

the possibilities of primary suture and healing. But the reward in personal satisfaction and in the gratefulness of the patient is so great as to make the effort very much worthwhile.

Methods of Approach.—The method of approach for the performance of the radical operation does not materially alter the possibility of doing a resection in continuity and retaining the sphincter. The latter may be combined with any of the types of combined abdominoperineal or abdominosacral approach and technic as well as with purely posterior types of operation via the sacral or perineal route. In the light of our present knowledge of the spread of the disease, the type of operative approach should depend on whether the growth is entirely below the peritoneum, above and below, or entirely above, as well as on whether the disease is still local or has spread to the lymphatic channels.

Local Resection.—In general, it may be stated that in about half the cases that may be cured by surgery, the disease can be successfully eradicated equally as well by local excision as by total proctectomy. This should stimulate surgeons to consider a modified radical excision when conditions appear favorable. One very remarkable case, out of a number of similar cases in my own experience, is the following. In 1928, a small ulcerating carcinoma was removed by a local resection, which did not include the entire circumference of the bowel, through a sacral approach. At the present writing (thirteen-year follow-up) the patient is perfectly well in every sense of the word.

Posterior Operations.—Conservative, sufficiently radical resection of the rectum in continuity, with immediate end-to-end direct anastomosis, can be carried out from below. The method was used by Grey-Turner with considerable success in 1935, and by Wood and Wilkie earlier.¹⁵ The various steps of the operation include incision along the left border of the sacrum wall down below the coccyx, with excision of the coccyx and, if necessary, the lower segment of the sacrum; sufficient successive liberation of the posterior, lateral, and anterior aspects of the rectum with as much of its neighboring soft tissues as possible, including the rectal fatty capsule, mesorectum, and glands well into undoubtedly healthy tissue. Commonly, extension of the tumor makes opening of the peritoneal cavity necessary, which facilitates removal of the highly located retrorectal lymph nodes. The tumor-bearing portion of the rectum is sectioned with

the thermocautery between clamps and the proximal extremity is sutured to the anal stump in the orthodox manner.

One refinement of technic, which I have found has added to the success of healing by immediate union, has been a three-layer suture: one for the mucosa, one for the mesial fibrous and muscular layer, and one for whatever peritoneal layer is available plus the rectal capsule.

In very favorable cases, especially in women with a justo major type of pelvis and with an extraordinarily wide interval between the two tuberosities of the ischia, it is possible to avoid resection of the sacrum and sometimes even of the coccyx in removing these growths from below. This is the perineal type of operation. It carries the added advantage that the immediate mortality of the operation is less, that the time of convalescence and healing is much shortened, and that all the inconvenience, pain, danger of secondary hemorrhage, etc., inherent in a wound containing infected bone are eliminated.

All growths below the peritoneum that are reasonably early and mobile should be thus removed by the perineal or sacral method rather than by a combined operation, and whenever feasible with immediate anastomosis. Those that are partly above and partly below can, in many instances, be dealt with in the same way, provided that they are not too far advanced.

Combined Operations.—For the latter type of case, however, and for all operable cases in which the evidence points to advanced disease, with the exception of those growths above the reflection which can be dealt with radically by Hartmann's operation, the combined abdominoperineal or abdominosacral procedure is indicated. I am personally not in favor of reversing this procedure into a perineo-abdominal or sacro-abdominal operation. In my opinion, this is a technical error; it increases the technical difficulties and the risks of infection. There is distinctly more danger in operations begun by the sacral method which must be concluded by another method, necessitating moving the patient several times. Such interventions have an excessively high mortality and should be avoided. If one decides to remove a carcinoma of the rectum through a sacral or perineal approach, there should be

Diagnosis

CLINICOPATHOLOGIC CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

Conducted by: Dr. Max Trubek

Date: May 7, 1942

History

DR. FRANK J. RUMMEL: This was the first admission to Bellevue of a 39-year-old white man who had no knowledge of previous illness until three years ago, when he was told that he had high blood pressure and albuminuria. At that time he had nocturia (two or three times) but felt fairly well until two years ago, when he had an attack of migratory polyarthritis lasting about three weeks, for which he was treated in another hospital. There he was told he had a "weak heart." Tonsillectomy was done soon afterward. During the past two years he had dyspnea on exertion and occasional palpitation. About one week prior to admission the patient developed an upper respiratory infection with sore throat. Five days before admission, he began to experience pains and swelling in the small joints of both feet, which later involved the right shoulder and the right hand as well. The arthralgia was associated with elevation of temperature and malaise. The past history included scarlet fever and influenza in childhood.

On physical examination, the patient was a well-developed and well-nourished white man, not appearing ill at the time of admission. There was no dyspnea, orthopnea, cyanosis, or clubbing of the fingers. The temperature was 105 F.; pulse, 95 per minute; respiratory rate, 20 per minute; and blood pressure, 160/100. The head and scalp were negative. The pupils were round, regular, and equal and reacted to light and accommodation. The extra-ocular muscles were normal. Examination of the ears and nose was negative; the pharynx was injected. There was no glandular enlargement, and the neck veins were not distended. On examination of the lungs, a few fine rales were noted at both bases posteriorly. The heart was enlarged to the left and right; there was roughening of the apical first sound, and the second pulmonic sound was very loud and snapping. There was an irregular rhythm,

as of auricular fibrillation. Liver dullness was percussible three finger breadths below the right costal margin. The kidneys and spleen were not palpable. There was moderate swelling and tenderness of ankles, knees, and hands. The reflexes were physiologic.

The patient was treated with aspirin, 1 Gm. every four hours. On the day following admission, the patient's temperature fell from 105 F. to 98 F., but thereafter increased to an average of about 100.5 F. His pulse rate increased, and weakness and dyspnea became prominent. On March 3, 1942, the eleventh day of his hospital stay, a double mitral murmur with a presystolic thrill was noted. He began to have precordial pain and discomfort and increased dyspnea. Dullness and rales were present over the left lower lobe; on April 3, flatness and frank bronchial breathing were found over the left posterior chest, with moist rales at both bases. The diagnosis of left lower lobe lobar pneumonia was made, and oral sulfadiazine therapy was begun.

The temperature did not respond to sulfadiazine (sulfadiazine level was 16 mg.), and the drug was discontinued on April 6, after three days, and digitalization was begun. At this time the patient disclosed that he had coughed up several small pieces of blood during his first three days in the hospital. The sulfadiazine level in the blood dropped to 6.8 mg. On April 7, sulfadiazine was resumed, and thoracentesis was done, with the removal of 40 cc. of cloudy yellow fluid containing 675 white blood cells with 40 per cent polymorphonuclears and 60 per cent lymphocytes. Culture of this fluid was negative. On April 9, sulfadiazine and digitalis were discontinued. At this time the pulse was regular, of fairly good quality, but very rapid. The lung signs were the same as on previous examination. On April 10, hematuria was noted for the first time. On that day thoracentesis was repeated, and 450 cc. of serosanguineous fluid was withdrawn. The specific gravity of the chest fluid was 1.017. On April 11, the temperature rose to 103.8 F.; the pulse was irregular (coupling) and of very poor quality.

end-to-end anastomosis, was done in October, 1936. In January, 1941 (four and one-half year follow-up), he was well and free from recurrence. He has a small residual fistula, undoubtedly due to stricture formation, but refuses to permit the necessary plastic operation which might close the fistula.

Case 7.—D. R., a woman in the fourth decade of life, had a carcinoma of the rectosigmoid for which a combined abdominosacral resection of the rectum in continuity, with immediate end-to-end suture, was done in February, 1936. In December, 1936, a small recurrence at the site of the anastomosis was excised, again with immediate suture through a posterior approach. In January, 1941 (five-year follow-up), the patient was well, with no sign of recurrence. A pin-point residual fistula is present in the posterior wound, which discharges nothing, does not inconvenience her in the least, and for which nothing should be done.

Case 8.—B. S., a 48-year-old woman, had an adenocarcinoma of the rectosigmoid just at the peritoneal reflection. A combined abdominosacral resection of the rectum in continuity, with immediate end-to-end suture, was done in March, 1935, after a preliminary cecostomy had previ-

ously been established. Postoperative stricture at the suture line was treated by dilatation and later by division of the stricture. Complete healing then followed. In September, 1936, the cecostomy was closed successfully. At present, the patient is free from recurrence and the bowel evacuations are normal (six-year follow-up).

WALKING AIDS MENTAL HEALTH

A daily walk, aside from conferring many physical benefits, actually improves the mental condition tremendously. E. A. Conklin, Norwich, New York, says in the May issue of *Hygeia*. He points out that "If you are inclined to be melancholy when you awake in the morning, a walk will help chase away your depression. If you have deep-rooted worries on your mind, walking will give your brain a temporary respite and allow you to face your difficulties a little later on with renewed vitality.

"If you haven't walked to amount to anything since childhood, you should exercise a little care in the preliminary steps of becoming an expert hiker. . . . For a beginner, a mile is sufficient. The experienced walker can gracefully stand four times as much. Walkers find that by gradually increasing the scope of their walk at the rate of an additional half mile each week, they are soon able to look a five-mile hike in the face without wincing."

Posture, Mr. Conklin advises, is of greatest importance in getting the maximum in pleasure and profit from the daily walk. "Watch yourself in the store windows as you stride along," he suggests. "You miss half the joys life can offer you if your head is up in the clouds or directed to the street beneath your feet. Try being comfortably erect, watching and checking on yourself at frequent intervals. . . ."

If possible, the author says, walking expeditions should be made in the early morning. They

tend to stimulate the jaded appetite, and after several weeks a feeling of increased well-being will become apparent. The average person has no difficulty in completing a three or four mile walking tour in little more than an hour; thus by rising slightly earlier than usual, one can reach home in time for a satisfactory breakfast.

"If it is impossible to walk in the early morning hours," Mr. Conklin continues, "the next best walking time is late afternoon, when the sun is fading and its heat is no longer severe. . . . The important thing is to set oneself in motion at a regular time each day. Regular hours are essential until walking becomes a fixed habit, unbreakable and enjoyable.

"Every Saturday or Sunday afternoon may be made a family hiking occasion, with the youngsters and the rest of the family journeying to a not too distant park or mountain. A picnic lunch packed on the back will add to the enjoyment of such week-end festivities. Boys and girls who learn to walk while young will not dread it when approaching manhood or womanhood. No matter how enthusiastic a sports fan your youngster is, he may be expected at first to shy away from anything as simple as walking.

"On your expeditions you will notice many curiosities of nature, some new, others familiar, but all keeping your mind attentive and free of the daily wear and tear so common in our complex modern lives. By all means, take a walk—today and every day!"

The arthralgia was associated with elevation of temperature and malaise. The past history included scarlet fever and influenza in childhood.

On physical examination, the patient was a well-developed and well-nourished white man, not appearing ill at the time of admission. There was no dyspnea, orthopnea, cyanosis, or clubbing of the fingers. The temperature was 105 F.; pulse, 95 per minute; respiratory rate, 20 per minute; and blood pressure, 160/100. The head and scalp were negative. The pupils were round, regular, and equal and reacted to light and accommodation. The extra-ocular muscles were normal. Examination of the ears and nose was negative; the pharynx was injected. There was no glandular enlargement, and the neck veins were not distended. On examination of the lungs, a few fine rales were noted at both bases posteriorly. The heart was enlarged to the left and right; there was roughening of the apical first sound, and the second pulmonic sound was very loud and snapping. There was an irregular rhythm,

as of auricular fibrillation. Liver dullness was percussible three finger breadths below the right costal margin. The kidneys and spleen were not palpable. There was moderate swelling and tenderness of ankles, knees, and hands. The reflexes were physiologic.

The patient was treated with aspirin, 1 Gm. every four hours. On the day following admission, the patient's temperature fell from 105 F. to 98 F., but thereafter increased to an average of about 100.5 F. His pulse rate increased, and weakness and dyspnea became prominent. On March 3, 1942, the eleventh day of his hospital stay, a double mitral murmur with a presystolic thrill was noted. He began to have precordial pain and discomfort and increased dyspnea. Dullness and rales were present over the left lower lobe; on April 3, flatness and frank bronchial breathing were found over the left posterior chest, with moist rales at both bases. The diagnosis of left lower lobe lobar pneumonia was made, and oral sulfadiazine therapy was begun.

The temperature did not respond to sulfadiazine (sulfadiazine level was 16 mg.), and the drug was discontinued on April 6, after three days, and digitalization was begun. At this time the patient disclosed that he had coughed up several small pieces of blood during his first three days in the hospital. The sulfadiazine level in the blood dropped to 6.8 mg. On April 7, sulfadiazine was resumed, and thoracentesis was done, with the removal of 40 cc. of cloudy yellow fluid containing 675 white blood cells with 40 per cent polymorphonuclears and 60 per cent lymphocytes. Culture of this fluid was negative. On April 9, sulfadiazine and digitalis were discontinued. At this time the pulse was regular, of fairly good quality, but very rapid. The lung signs were the same as on previous examination. On April 10, hematuria was noted for the first time. On that day thoracentesis was repeated, and 450 cc. of serosanguineous fluid was withdrawn. The specific gravity of the chest fluid was 1.017. On April 11, the temperature rose to 103.8 F.; the pulse was irregular (coupling) and of very poor quality.

The patient became comatose and very dyspneic. The heart sounds were well heard. Sodium sulfathiazole was given, without subsequent improvement, and the patient died the following day.

Laboratory Data.—Urinalysis: color, amber; specific gravity, 1.010; reaction, acid; 3 plus albumin, no glucose; microscopic examination revealed granular and hyaline casts and many white blood cells. Urinalysis (April 11): bloody; specific gravity, 1.020; 2 plus albumin, no glucose; microscopic examination showed the urine to be loaded with red blood cells and white blood cells. The white blood count was 11,000, with 83 per cent polymorphonuclears and 17 per cent lymphocytes. The red blood count was 4,100,000, with 80 per cent hemoglobin. On March 22, the erythrocyte sedimentation rate was 78 mm. per hour, and on April 3 it was 88 mm. per hour. The blood cultures were repeatedly negative. The blood nonprotein nitrogen was 37. An electrocardiogram, on March 30, showed rapid sinus rhythm, partial auriculoventricular block, and marked acute myocardial changes. The PR interval was 0.28 second. A second electrocardiogram, taken on April 6, showed rapid sinus rhythm with marked partial auriculoventricular block. The PR interval was 0.32 second, and the QRS interval was 0.08 second. Another electrocardiogram, on April 10, showed sinus tachycardia with partial block, as before; right electrical axis deviation; PR interval 0.24 second and QRS interval 0.10 second. A roentgenogram of the chest, taken on April 3, showed the heart to be markedly enlarged in all diameters, with accentuation of the pulmonic conus and straightening of the left cardiac border. There were congestive changes of both lung fields, with an area of pleural effusion on the left, extending to the level of the second anterior rib; and an area of pneumonitis at the right base.

Discussion

DR. MAX TRUBEK: The patient had his first knowledge of any illness three years ago, when he was told of high blood pressure and albuminuria. He has had increased urinary frequency, with occasional reddish urine (according to admission history), as well as nocturia (two or three times).

His present illness began with the classical manifestations of recurrent acute rheumatic fever, sore throat, and running nose about ten days prior to admission, which improved. But five days before admission he developed

multiple migratory swollen, painful joints, and there was an elevation of temperature.

Two years ago the patient had a similar attack, which was diagnosed as rheumatic fever and rheumatic heart disease. There had been dyspnea with extra effort, and there had been a cough, with thick, occasionally bloody sputum.

The patient had scarlet fever as a child, and tonsillectomy was done one year ago.

We shall discuss the pathologic possibilities dividing the major illness into the chief categories of organic involvement:

1. *Cardiac.*—We have every reason to expect acute and chronic rheumatic carditis. There are the double mitral murmur, with evidence of pulmonary and hepatic congestive failure, the persistently elevated erythrocyte sedimentation rate, the continuous spiking fever, and the electrocardiographic finding of partial auriculoventricular block, with PR interval up to 0.32 second—these, aside from other alterations of active myocardial damage. The chest x-ray seems to confirm a mitral cardiac configuration.

Could we expect subacute bacterial endocarditis superimposed? It is very unusual to have swollen, red joints during subacute bacterial endocarditis. Arthralgias are common. Very occasionally, the two diseases coexist. No petechiae were noted. The spleen could not be felt, and all blood cultures were negative. The mitral murmur was seemingly accentuated during the hospital stay, and there were renal complications—somewhat unusual for rheumatic fever alone. There was no incidental improvement during chemotherapy.

2. *Kidneys.*—There was a definite history of hypertension preceding the rheumatic fever. At least, the patient knew nothing of a murmur at that examination. The hospital urine specific gravities were recorded between 1.010 and 1.020—seemingly at variance with any diffuse glomerulonephritis. Granular and hyaline casts were a constant finding. There were always many white blood cells, occasional red blood cells, and in one instance the urine was loaded with red blood cells. The initial blood pressure was 160/100, a preterminal one was 140/68. None other was recorded. The urinary abnormalities were present on admission and preceded the use of sulfadiazine. It was, however, recorded that the patient attended the Third Medical Division Clinic for one year and was ordered to take one white tablet daily—possibly a prophylactic dose of a sulfonamide? There

was only slight anemia. A chronic pyonephritis might account for the picture and explain particularly the large number of white blood cells and the absence of evidence of widespread glomerulitis. The final appearance of blood might be due to renal infarction, especially since there was the clinical record of inconstant auricular fibrillation, with possible auricular mural thrombi as the source. Without evidence, we cannot postulate an embolic glomerulonephritis. Active rheumatic fever can occasionally cause a widespread renal arteriolitis and glomerulitis, but this would not account for the three years' or more renal history, unless we called it latent, and plus an acute glomerulonephritis.

3. *Lungs*.—On admission, there were fine moist rales at both bases and the second pulmonic sound was markedly accentuated—confirmatory evidence of pulmonary congestive failure. During the second week, the patient appeared more acutely dyspneic, and signs at the left base were interpreted as those of consolidation. There was no alteration in the continued spiking temperature, which was present from the time of admission. There was no benefit from adequate chemotherapy. Nearly one-half liter of clear fluid was subsequently withdrawn from this area, with the characteristics of a nonpurulent exudate. Compression breathing could have simulated consolidation; the source of the fluid may have been from an active rheumatic involvement of the pleura. Moist rales appeared throughout both lungs. The white blood count never exceeded 12,000. There was adequate evidence of pulmonary congestive failure, and with the story of blood in the sputum, there is the possibility of a chronic pulmonary stasis with pulmonary induration. This would rather limit the "rheumatic" involvement to the serous surfaces of the lungs.

DR. HERMAN O. MOSENTHAL: There was a distinct diastolic murmur, which was not recorded on physical examination. At the time, I interpreted this as indicating an aortic insufficiency. Particularly noteworthy was the accentuation of the second pulmonic sound, which gave the sensation of a diastolic shock on palpation, and which was so loud that it could be heard at a little distance from the chest without the stethoscope or the ear being applied to the chest. The lesions in the lung were somewhat of a puzzle to us. The signs were those of a consolidation in the left lower lobe. Since the administration of sulfadiazine did not lower the temperature and bloody sputum developed, I was of the

opinion that there was an infarct of the lung. A suggestion made by Dr. Eleanor Galenson (senior intern) that this was a "rheumatic pneumonia" deserves consideration. From the urinalysis, it was impossible to make any final judgment on the kidneys. The hematuria might have been significant of passive congestion, acute nephritis, or infarcts of the kidneys. The urinalysis of March 11, with a specific gravity of 1.020 and the appearance of hematuria, makes any one of these three diagnoses possible. The preceding albuminuria without hematuria was in all probability a febrile albuminuria and nothing more than that. The subsequent occurrence of hematuria indicated some further pathology.

DR. HARRY A. SOLOMON: Looking at the x-ray plate, one can infer the presence of both aortic and mitral lesions because of the left ventricular enlargement. However, hypertension, known to exist in this case, was probably the cause of the aortic configuration of the heart. The clinical picture is clearly one of rheumatic fever, and because of the signs in the left chest, suggestive of Ewart's sign, pericardial effusion should be suspected, or at least the presence of "rheumatic pneumonia" should be considered also. The fact that the fever did not respond to the sulfa group is a strong diagnostic point against the presence of bacterial endocarditis. That both active rheumatic carditis and subacute bacterial endocarditis can coexist is well known. The bacterial infection usually begins insidiously. The renal picture can be explained on the basis of glomerulonephritis, which is a rare complication of rheumatic fever, but in this case should favor the presence of subacute bacterial endocarditis.

DR. MAX TRUBEK: There is no real evidence of aortic involvement. The second pulmonic sound is not usually accentuated unless there is pulmonary involvement or pulmonary congestive failure.

DR. ARNOLD KOFFLER: Essentially, the production of hematuria may be based on two possibilities: first, the result of chemotherapy, in which case crystals should be present in the urine; and, secondly, the possibility of infarction as the result of subacute bacterial endocarditis.

DR. MAX TRUBEK: This man had casts in his urine; I believe the kidney pathology to be more than a sulfadiazine reaction.

Pathology

Gross Pathology.—DR. ROGER W. STEINHARDT: At autopsy, the heart weighed 580

The patient became comatose and very dyspneic. The heart sounds were well heard. Sodium sulfathiazole was given, without subsequent improvement, and the patient died the following day.

Laboratory Data.—Urinalysis: color, amber; specific gravity, 1.010; reaction, acid; 3 plus albumin, no glucose; microscopic examination revealed granular and hyaline casts and many white blood cells. Urinalysis (April 11): bloody; specific gravity, 1.020; 2 plus albumin, no glucose; microscopic examination showed the urine to be loaded with red blood cells and white blood cells. The white blood count was 11,000, with 83 per cent polymorphonuclears and 17 per cent lymphocytes. The red blood count was 4,100,000, with 80 per cent hemoglobin. On March 22, the erythrocyte sedimentation rate was 78 mm. per hour, and on April 3 it was 88 mm. per hour. The blood cultures were repeatedly negative. The blood nonprotein nitrogen was 37. An electrocardiogram, on March 30, showed rapid sinus rhythm, partial auriculoventricular block, and marked acute myocardial changes. The PR interval was 0.28 second. A second electrocardiogram, taken on April 6, showed rapid sinus rhythm with marked partial auriculoventricular block. The PR interval was 0.32 second, and the QRS interval was 0.08 second. Another electrocardiogram, on April 10, showed sinus tachycardia with partial block, as before; right electrical axis deviation; PR interval 0.24 second and QRS interval 0.10 second. A roentgenogram of the chest, taken on April 3, showed the heart to be markedly enlarged in all diameters, with accentuation of the pulmonic conus and straightening of the left cardiac border. There were congestive changes of both lung fields, with an area of pleural effusion on the left, extending to the level of the second anterior rib; and an area of pneumonitis at the right base.

Discussion

DR. MAX TRUBEK: The patient had his first knowledge of any illness three years ago, when he was told of high blood pressure and albuminuria. He has had increased urinary frequency, with occasional reddish urine (according to admission history), as well as nocturia (two or three times).

His present illness began with the classical manifestations of recurrent acute rheumatic fever, sore throat, and running nose about ten days prior to admission, which improved. But five days before admission he developed

multiple migratory swollen, painful joints, and there was an elevation of temperature.

Two years ago the patient had a similar attack, which was diagnosed as rheumatic fever and rheumatic heart disease. There had been dyspnea with extra effort, and there had been a cough, with thick, occasionally bloody sputum.

The patient had scarlet fever as a child, and tonsillectomy was done one year ago.

We shall discuss the pathologic possibilities dividing the major illness into the chief categories of organic involvement:

1. **Cardiac.**—We have every reason to expect acute and chronic rheumatic carditis. There are the double mitral murmur, with evidence of pulmonary and hepatic congestive failure, the persistently elevated erythrocyte sedimentation rate, the continuous spiking fever, and the electrocardiographic finding of partial auriculoventricular block, with PR interval up to 0.32 second—these, aside from other alterations of active myocardial damage. The chest x-ray seems to confirm a mitral cardiac configuration.

Could we expect subacute bacterial endocarditis superimposed? It is very unusual to have swollen, red joints during subacute bacterial endocarditis. Arthralgias are common. Very occasionally, the two diseases coexist. No petechiae were noted. The spleen could not be felt, and all blood cultures were negative. The mitral murmur was seemingly accentuated during the hospital stay, and there were renal complications—somewhat unusual for rheumatic fever alone. There was no incidental improvement during chemotherapy.

2. **Kidneys.**—There was a definite history of hypertension preceding the rheumatic fever. At least, the patient knew nothing of a murmur at that examination. The hospital urine specific gravities were recorded between 1.010 and 1.020—seemingly at variance with any diffuse glomerulonephritis. Granular and hyaline casts were a constant finding. There were always many white blood cells, occasional red blood cells, and in one instance the urine was loaded with red blood cells. The initial blood pressure was 160/100, a preterminal one was 140/68. None other was recorded. The urinary abnormalities were present on admission and preceded the use of sulfadiazine. It was, however, recorded that the patient attended the Third Medical Division Clinic for one year and was ordered to take one white tablet daily—possibly a prophylactic dose of a sulfonamide? There

Spleen: old and recent infarcts, with septic splenitis.

Kidneys: recent infarct, left with arterial nephrosclerosis and sclerotic infarcts of the kidneys.

Liver: chronic passive congestion.

Lungs: chronic passive congestion. Intra-alveolar hemorrhage. Minimal hemorrhagic pleural effusion, left.

BABE RUTH AND THE DOCTORS

The Great Bambino on his return from the West Coast offered the perfect example of the average man who has just been delivered miraculously from a critical illness. "I'm smoking my usual quota," he told reporters. "Ten or fifteen cigars a day." Actually, at the moment he was abstaining from cigars. When he arrived he was smoking instead a 40-year-old pipe, given to him by a Hollywood friend.

In other respects, he had been taking it easy. Before going to the Coast to make a movie on Lou Gehrig's life, he had been ordered to curtail his golfing, bowling, and smoking. So he cut down on the golfing and bowling—being, presumably, pretty busy with the picture anyway—and played only six games of golf while out there, and bowled six times.

In other words, the Babe had cut out the things which, if done temperately, might possibly have been beneficial to him, while continuing furiously the smoking, which might conceivably—although here we run into sharply contradictory evidence—shorten his life. "I can't seem to stop smoking," he says, while proudly adding, "but anyway I'm not drinking."

Example of the Doctors.—There is something plaintively appealing about the great home-run slugger being subject to the weaknesses of the ordinary man. Ruth is in his late forties. He has become accustomed to his cigar and, to make a rough estimate, feels more comfortable with one in his mouth about half of his waking hours. Probably he has been spoken to quite sharply by the doctors, his family, and his friends about this matter of smoking.

Usually the conversation with the doctor goes something like this: "Do you smoke much?" "Well, quite a good deal." "Notice any ill effects?" "No-o-o, not particularly." "What do you smoke?" "Cigars." The doctor pauses. "Well, you'd better cut them out."

As the patient is ushered out, the doctor usually lights up a cigarette himself and, not infrequently, with generous absent-mindedness, offers the patient a smoke himself. The patient, being

a cigar smoker, is not greatly tempted. He may even wait until he gets to the next corner before he reaches into his coat pocket and starts violating the doctor's orders again.

When the Adviser Gets Old.—The doctors have only themselves to blame if their patients are, to a considerable extent, puzzled by the contradictory evidence between their prescriptions and their own conduct. Many smoke and some drink—and rule against these for their patients, or for some of them.

If the doctor is a young man, he plays a fast and strenuous game of tennis and squash racquets, and advises his patients to get more exercise. Here he takes on the mantle of consistency. If the pressing demands of his practice finally, as he grows into middle age, prevent the doctor from getting to the courts consistently, he begins to give up the game. He now finds that when he does occasionally play it is a bit too strenuous, and begins to warn his middle-aged patients that they had better take up chess or bridge for exercise.

Long Life and Sports.—This is not said by way of being critical of the doctors. A physician would hardly be worthy of his profession if he did not consistently examine himself as well as his patients to try to discover the ways of health. If he finds that smoking and drinking in moderation do not seem to affect himself adversely, or too adversely, he indulges. If certain sports seem to him, at forty, to be too much of a strain, he would be less than human if he didn't measure patients by the standards applied to himself.

Yet people who enjoy their tobacco and their sports will probably rest their own case—human nature being what it is—on Dr. Logan Clendenning's thesis. He, after discussing tobacco, exercise, and longevity, says: "An impartial examination of all the means yet proposed to prevent early death or lengthen life leaves me with the conviction that nothing anybody does to himself after he is born makes more than a few hours' difference at the most."—*Reprinted with permission from The New York Times*

State medicine, in my opinion, bears disaster for doctor and patient alike. You cannot pipe out medicine to the community as you do with steam heat.—Dr. A. J. Cronin, *English author of The Citadel, Keys of the Kingdom*

No physician, in so far as he is a physician, considers his own good in what he prescribes; for the true physician is also a ruler having the human body as a subject and is not a mere money-maker.—Plato

Gm. It was covered with layers of shaggy fibrin which completely obliterated the pericardial sac. All chambers of the heart were dilated, and the myocardium was everywhere hypertrophied. No thrombi were seen in the auricles or their appendages. The mitral valve was stenotic. This stenosis was due chiefly to a large papillary-like vegetation on thickened leaflets. A great part of the vegetation was calcified, and a culture from this vegetation grew *Streptococcus viridans*. The chordae tendineae were fused, shortened, and thickened. The leaflets of the aortic and tricuspid valves showed moderate rolling of the free edges, and tiny verrucae could be seen. The coronaries were natural. About 40 cc. of serosanguineous fluid was found in the left chest. The lungs themselves were deeply congested but nowhere consolidated. No infarcts were seen. Infarcts were found, however, both in the spleen, which weighed 380 Gm., and in the kidneys. The kidneys themselves also presented a deeply scarred surface and some thickening of the pelvis, probably indicative of an old pyelonephritis. The liver showed chronic passive congestion.

Discussion

DR. MAX-WILHELM JOHANNSEN: At the time of necropsy, the examination of the heart showed this very large sclerotic and partially calcified lesion to be situated at the junction of the posterior and anterior mitral leaflets. Several verrucae, to my mind indistinguishable from those frequently seen on calcified plaques, were noted. Only after seeing the infarcts of the kidney and spleen did we make a diagnosis of a vegetative bacterial endocarditis superimposed on this sclerotic calcified plaque. As you all know, subacute bacterial endocarditis is usually superimposed on an old rheumatic valvulitis. As a matter of fact, Dr. Von Glahn has shown that 45 per cent of the patients coming to necropsy and presenting subacute bacterial endocarditis caused by *Str. viridans* have a "smoldering" rheumatic activity. It was thought that subacute bacterial endocarditis does not, as a rule, occur in acute rheumatic valvulitis. In my experience, that is not quite correct. In the last two years I have seen 4 cases in which this bacterial endocarditis was superimposed on an acute rheumatic valvulitis. It is true that a patient with fibrillation rarely develops subacute bacterial endocarditis. I believe that of this sequela only 4 authentic cases are reported in the literature. Likewise, a tight mitral stenosis is a protection

against the development of endocarditis lenta.

Microscopic examination showed a typical chronic active rheumatic pancarditis with involvement of all four sets of valves. Aschoff cells and even Aschoff bodies were seen in the myocardium, deep in the substance of the various leaflets, where, in addition, palisading of Aschoff cells was noted. Many old and recent blood vessels were present in the ring areas. Inflammatory cells were particularly abundant in the leaflets, and were present to a lesser degree in the myocardium. The epicardium showed a very distinct thick layer of fibrin, with marked vascularization of the epicardium proper. Section through the calcified plaque of the mitral leaflet showed, in addition to the obvious changes caused by sclerosis and calcification, many lymphocytes and polymorphonuclears in poorly outlined areas. Some necrosis was present. A gram-stain was not done because bacteriologic studies of this area revealed a pure culture of *Str. viridans*. The lungs did not reveal any findings that could be identified as specific for a rheumatic pneumonia, such as a rheumatic arteritis and the presence of Aschoff cells and Aschoff bodies in the interstitial tissues. The outstanding features were marked acute congestion and intra-alveolar hemorrhage superimposed on chronic passive congestion. Likewise, the pleura was free of any rheumatic or inflammatory manifestation. I am, therefore, unable to explain the left-sided pleural effusion. The spleen showed recent and fresh infarcts, and in the white pulp an abundance of polymorphonuclears was seen. The liver showed chronic passive congestion. The kidneys showed, in addition to the obvious infarcts, many large horseshoe-shaped depressed areas and a thickened, slightly injected pelvis. This latter finding is rather typical of a chronic pyelonephritis, which was substantiated by the microscopic finding of foci of scarring of the parenchymal and interstitial tissue and dilatation of many tubules which were filled with an eosinophilic staining, homogeneous acellular material. The pelvis was thickened and showed aggregations of lymphocytes.

Anatomic Diagnosis

Rheumatic pancarditis with superimposed subacute bacterial endocarditis.

Mitral stenosis.

Mitral insufficiency.

Generalized cardiac hypertrophy and dilatation.

Spleen: old and recent infarcts, with septic splenitis.

Kidneys: recent infarct, left with arterial nephrosclerosis and sclerotic infarcts of the kidneys.

Liver: chronic passive congestion.

Lungs: chronic passive congestion. Intralveolar hemorrhage. Minimal hemorrhagic pleural effusion, left.

Medical Preparedness

Recruiting of Medical Officers

TO STEP up the entrance of medical officers into the United States Army, and to shorten the process, there have been set up in New York State seven "Medical Officers' Recruiting Boards." All physicians below the age of forty-five who are citizens can avoid delays and clear up questions by visits to the nearest of these offices.

Information comes that for those receiving commissions who need time to settle their home affairs, these boards have the power to recommend to the Surgeon General a reasonable period before they are called into service (even, on exception, up to ninety days).

The Boards are located as follows:

City	Address	Recruiting Officer
Albany	Federal Building	Major E. K. Reid
Binghamton	Federal Building	Major E. K. Reid
Buffalo	Federal Building	Major E. K. Reid
New York	39 Whitehall Street	Captain J. J. McMahon
Rochester	Federal Building	Major E. K. Reid
Syracuse	Federal Building	Major E. K. Reid
Utica	Federal Building	Major E. K. Reid

House of Delegates

Minutes of the Annual Meeting

April 27 and 28, 1942

THE 136th Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Waldorf-Astoria Hotel, New York City, on Monday, April 27, 1942, at 10:10 A.M.: Dr. Louis H. Bauer speaker; Dr. William Hale, vice-speaker, Dr. Peter Irving, secretary; Dr. Edward C. Podvin, assistant secretary.

SPEAKER BAUER: The House will be in order Ladies and Gentlemen, The National Anthem! The delegates sang "The Star-Spangled Banner". . . .

Section 1

Report of the Reference Committee on Credentials

SPEAKER BAUER: The chair recognizes Dr Peter Irving, chairman of the Reference Committee on Credentials.

SECRETARY IRVING: Mr Speaker, there are no disputed delegates All who have been seated, and are on our rolls, are entitled to vote

SPEAKER BAUER: I declare the 136th Session of the House of Delegates to the Medical Society of the State of New York open for the transaction of business

SECRETARY IRVING: There is a quorum present.

SPEAKER BAUER: The secretary reports a quorum present. It has been customary in previous years to call the roll by counties, which is purely for the purpose of determining whether or not a quorum is present. Unless there is objection, we will take the secretary's word for it, and save time. Hearing none, it is so ordered

Section 2

Approval of the Minutes of the 1941 Session

SPEAKER BAUER: The first order of business is the approval and adoption of the minutes of the 1941 Session of the House.

SECRETARY IRVING: I move you that the reading of the minutes of the 1941 Session of the House be dispensed with, and that they be approved and adopted as published in the June 15 and July 1 issues of the NEW YORK STATE JOURNAL OF MEDICINE.

DR LOUIS A. VAN KLEECK, *Nassau* I second that motion.

. . . There being no discussion, the motion was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: I will ask the secretary to read the Reference Committee appointments

Section 3

Reference Committees

SECRETARY IRVING: The Reference Committees of the 1942 House of Delegates are as follows:

REFERENCE COMMITTEE ON CREDENTIALS

Peter Irving, *chairman*, New York County
Archibald K. Benedict, Chenango County
Lyman C. Lewis, Allegany County
Charles F. McCarty, Kings County
Edward C. Podvin, Bronx County

REFERENCE COMMITTEE ON REPORT OF PRESIDENT

Carlton D. Wertz, *chairman*, Erie County
Stephen H. Curtis, Rensselaer County
John S. Kenney, New York County
Dan Mellen, Oneida County
Herbert B. Smith, Steuben County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART I

Postgraduate Education

Albert F. R. Andresen, *chairman*, Kings County
Conrad Berens, New York County
Corbet S. Johnson, Tioga County
Charles A. Prudhon, Jefferson County
Daniel R. Reilly, Cortland County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART II

Public Health Activities
4-H Club and Youth Activities
War Medicine and Surgery
Venereal Disease Control
Tuberculosis Conference Committee
Deaf and Hard of Hearing

Peter J. Di Natale, *chairman*, Genesee County
J. Lewis Amster, Bronx County
Robert Brittain, Delaware County
Morris Maslon, Warren County
Rudolph D. Moffett, New York County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART III

School Health Program

Leo F. Schiff, *chairman*, Clinton County
John D. Carroll, Rensselaer County
Thomas M. D'Angelo, Queens County
Louis A. Friedman, Bronx County
Ralph Sheldon, Wayne County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART IV

Publications, Journal, Director, and Medical Publicity

Andrew A. Eggston, *chairman*, Westchester County
Charles A. Anderson, Kings County
Albert A. Cinelli, New York County
James Greenough, Otsego County
William A. MacVay, Monroe County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART V

Nonprofit Medical Expense Insurance

F. Leslie Sullivan, *chairman*, Schenectady County
Albert A. Gartner, Erie County
H. P. Mencken, Queens County
William B. Rawls, New York County
Andrew Sloan, Oneida County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART VI

Medical Relief

Roy B. Henline, *chairman*, New York County
George A. Burgin, Herkimer County
Maurice J. Dattelbaum, Kings County
Guy S. Philbrick, Niagara County
Bernard S. Strait, Yates County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART VII:

Legislation

Walter P. Anderson, *chairman*, New York County
 Eugene H. Coon, Nassau County
 B. Wallace Hamilton, New York County
 Leo E. Reimann, Cattaraugus County
 Moses A. Stivers, Orange County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART VIII:

Medical Preparedness

Frederic W. Holcomb, *chairman*, Ulster County
 Emil Koffler, Bronx County
 Albert G. Swift, Onondaga County
 Arthur F. Heyl, Westchester County
 Thomas B. Wood, Kings County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART IX

Workmen's Compensation

Coburn A. L. Campbell, *chairman*, Suffolk County
 Robert F. Barber, Kings County
 Milton S. Lloyd, Richmond County
 Charles L. Pope, Broome County
 William W. Street, Onondaga County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART X.

Public Relations and Economics

Disposition of Registration Fees

Fines for Late Registration

Health and Accident Insurance for Interns

Medical Examination of Motor Vehicle Drivers

Physical Examination for Federal Civil Service

Recommendations for the Improvement of the Coroner System in New York State. Better Post-mortem Examinations

Homer L. Nelms, *chairman*, Albany County
 John J. Buettner, Onondaga County
 Walter D. Ludlum, Kings County
 Henry W. Miller, Putnam County
 Romeo Roberto, Westchester County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART XI

Special Matters

State Society Assessments and Service in Armed Forces

Financial Aid to County Societies for Medical Preparedness Work

Woman's Auxiliary

Continuation of Special Committees

Nominations for State Positions

Belated Bills

Proposition for the Economical Use of Medical Personnel

Protest Against Non-Inclusion in Medical Directory
 Committee for Interpretation of Medical Ethics
 1945 Convention of American Medical Association

Harry S. Bull, *chairman*, Cayuga County
 Emily D. Barringer, New York County
 Kenneth F. Bott, Greene County
 Thurber LeWin, Erie County
 G. Scott Towne, Saratoga County

REFERENCE COMMITTEE ON REPORT OF COUNCIL—PART XII

Malpractice Defense and Insurance

Legal Counsel

Moses H. Krakow, *chairman*, Bronx County
 Aaron Sobel, Dutchess County
 Joseph P. Henry, Monroe County
 John B. Lauricella, New York County
 Henry S. Martin, Wyoming County

There is no report of the Censors this year, we are glad to say.

REFERENCE COMMITTEE ON REPORTS OF THE SECRETARY AND DISTRICT BRANCHES

Stephen R. Monteith, *chairman*, Rockland County
 William G. Cooper, St. Lawrence County
 Edwin A. Griffin, Kings County
 Leon M. Kysor, Steuben County
 Denver M. Vickers, Washington County

REFERENCE COMMITTEE ON REPORTS OF THE TREASURER AND BOARD OF TRUSTEES

William Klein, *chairman*, Bronx County
 Clifford F. Leet, Chemung County
 Joseph C. O'Gorman, Erie County
 Stanley C. Pettit, Richmond County
 Walter L. Lynn, Queens County

REFERENCE COMMITTEE ON NEW BUSINESS A

Leo F. Simpson, *chairman*, Monroe County
 David W. Beard, Schoharie County
 DeForest W. Buckmaster, Chautauqua County
 Thomas A. McGoldrick, Kings County
 John L. Sengstack, Suffolk County

REFERENCE COMMITTEE ON NEW BUSINESS B

John J. Masterson, *chairman*, Kings County
 W. Guernsey Frey, Jr., Queens County
 Raymond F. Kircher, Albany County
 Charles C. Trembley, Franklin County
 Louis A. Van Kleeck, Nassau County

REFERENCE COMMITTEE ON NEW BUSINESS C

Harry C. Guess, *chairman*, Erie County
 John B. D'Albora, Kings County
 John L. Edwards, Columbia County
 Alfred M. Hellman, New York County
 John F. Kelley, Oneida County

Mr. Speaker, I move you that the reports of the officers, council, trustees, legal counsel, and district branches that have been published and distributed to the members of the House be referred to the respective reference committees without reading.

SPEAKER BAUER: Is there any objection to that being done?

.... There was no dissent.

SPEAKER BAUER: These reports were printed in the April 1 JOURNAL, and I think all the members of the House have had a reprint of those reports, so you are familiar with them. There being no objection, they will be so referred.

The reference committee tables are located in the balcony, and there are stenographers in the back of the room and on the balcony who will take your reports and resolutions, which must be submitted in quadruplicate. I should like to ask all officers of the Society and all Council Committee members to hold themselves in readiness to confer with the Reference Committees on the particular matters concerned, should their presence be desired.

Section 4 (See 30, 78)

Supplementary Report of the President

SPEAKER BAUER: Dr. Bandler, will you be a committee of one to escort the president of the Medical Society of the State of New York to the platform?

(The delegates arose and applauded as Dr. Clarence G. Bandler escorted Dr. Samuel J. Kopetzky to the platform.)

SPEAKER BAUER: It gives me great pleasure to welcome you here as president of the Medical Society of the State of New York.

Dr. Kopetzky certainly needs no introduction to this organization. He was speaker of this House, I believe, for five years, and for the past year has been your head. Gentlemen, the president of the Medical Society of the State of New York! (Applause)

PRESIDENT KOPETZKY: Mr. Speaker and Gentlemen of the House: To set an example, I have no supplementary report. To set another example, my remarks will be brief.

It is twenty-five years since this House of Delegates assembled during a war time. We are meeting under extraordinary circumstances. Let us see to it that the liberty and the four freedoms for which we are fighting are none of them lost in the planning for the successful outcome of this war.

You will remember that last year before this House I laid down a formula which has been my guiding principle during the period that I have had the honor and the privilege to head your organization. Again reiterating that principle, it is that all plans, as far as it is possible to conceive them, should be so conceived that with the demobilization of the Armed Forces and the cessation or stoppage of the emergency these procedures can also be demobilized.

I now wear the livery of our Uncle Sam. I take it that the time will not be too far distant but that many of you, too, will wear this honored livery. This morning I had official word of a new grouping as to the availability of doctors, and also as to their being essential. There is to be a group who will do temporary duty in the face of an instant emergency in a community. All doctors may be mobilized under that classification, to be centered where such emergency is acute and they are needed.

There is an overall general shortage of doctors throughout the country. We are fortunate in the State of New York, and a number of other states likewise are fortunate, inasmuch as we have an excess of the minimum necessity for medical men to serve in the community, so it is necessary in planning that we are able to send, from our storehouse of accumulated medical men, men where and if an acute catastrophic emergency may arise.

I hope that as you deliberate upon the various resolutions, as you determine policy, you will bear in mind the extraordinary circumstances under which we are meeting, and remember that no officer, no spokesman of yours, has the right to go beyond the determined policy of this House of Delegates in representing the medical profession.

Finally, my sincere thanks to all of you for your support, without which nothing that has been accomplished—and dramatic accomplishments were not my goal—would have been possible. What has been done has been done because I felt I had you behind me. My thanks! (Applause)

SPEAKER BAUER. This report is referred to the Reference Committee on the Report of the President, of which Dr. Carlton E. Wertz, of Buffalo, is chairman.

Section 5. (See 30)

Address of the President-Elect

SPEAKER BAUER: Dr. Johnson, will you be a committee of one to escort the president-elect of the Medical Society of the State of New York to the platform?

(The delegates arose and applauded as Dr. William D. Johnson, of Batavia, escorted Dr. George W. Cottis to the platform.)

SPEAKER BAUER: Gentlemen, one year ago you selected Dr. George W. Cottis, of Jamestown, to lead this organization as president-elect. We all felt at that time that a very wise choice had been made, and I know we are all still of the same opinion.

Dr. Cottis, I am sure the house would like to hear from you at this time. The president-elect, gentlemen! (Applause)

PRESIDENT-ELECT COTTIS: Mr. Speaker and members of the House of Delegates, I thank you for the high honor that you have seen fit to confer upon me. I accept it with pride and with humility and with a deep sense of responsibility.

I can remember when a new president could look forward to a year of stimulating and pleasant associations, with no particular fears and forebodings. He could feel quite sure that if he could satisfy Kings County, he would not have any serious troubles, provided that Westchester or Erie did not go on a rampage during his term of office. (Laughter)

I look forward to this coming year with no such pleasant anticipations. It is true that our profession is united as never before. We are as one man in our resolve to preserve the traditions of the most humanitarian of all callings, but we are faced with two great responsibilities: First, to give everything we have in talent, time, money, and even life itself, to help to preserve our country and the other free peoples of the world from a condition of darkest barbarism. Second, we have to meet with courage, faith, and statesmanship the threats to our ideals of service.

This world revolution that everybody talks about, and about which very few seem to comprehend the import, is not a revolution in the sense of the French or the American Revolution, it is as fundamental as the change from feudalism to free enterprise at the end of the Dark Ages. That change is already complete over a great part of the world. It is complete in Germany, Italy, Spain, Russia, Japan, and, for the time being at least, in all of the enslaved countries. We have faith in the ability of Americans to preserve American freedom, but we must not shut our eyes to the profound changes that have already been made in our mode of government during the last ten years.

We must face the fact that these changes will be accelerated with an increased tempo as the war continues. Two years ago, 27,000,000 Americans voted for the continuance of paternalism and bureaucratic control, after having had eight years in which to evaluate it. That is a trend, and it is a trend over which we, as a profession, have no control. We, doctors, have very little political influence. All that we have is an understanding of the problem of the care of the sick. All that we have is an unshakable resolve to merit the confidence of our patients, and a resolve to fight every attempt to shackle us in political bondage. All that we have is the knowledge, the altruism, the courage, and the unity which must, no matter what social changes may come, preserve for us our right to scientific freedom of thought, our right to continue the highest standard of service that this world has ever seen, the right to solve our own problems, and the right to be fully represented on any coun-

cil that may propose to change our relationship with our patients.

It is to preserve these rights that we shall be fighting on the seven seas and on every continent. We must see to it that we do not save our rights by war only to lose them in the peace that follows. We have that power. God grant that we have the unity, the loyalty, and the courage to win the battle on both fronts. (Applause)

SPEAKER BAUER: The chair will appreciate it if both the president and the president-elect will do him the honor of remaining on the platform.

The address of the president-elect is referred to the Reference Committee on the Report of the President, of which Dr. Wertz, of Erie, is the chairman.

Mr. Secretary, are there any supplementary reports?

SECRETARY IRVING: There are six, sir.

The first is from the Committee on Legislation, and was referred to in the published report, with an addendum, both of which have been distributed.

SPEAKER BAUER: Have these been distributed?

SECRETARY IRVING: They have, sir.

SPEAKER BAUER: If there is no objection, since they have been distributed and are before you for your information, they will not be read. Hearing none, it is so ordered.

Section 6. (See 32)

Supplementary Report of the Council—Part VII: Legislation

This report is reasonably complete up to April 21, 1942. The Legislature has not yet closed, so that an addendum report must be given later. If the Legislature closes this week end, our executive officer will attempt to have prepared mimeographed copies of final actions of the legislators taken after April 21. We must remember that the Governor has a thirty-day period in which to act upon bills referred to him. A report of his action will be given in a final bulletin.

Possibly those of us who have been appointed to study the many bills of medical and public health interest should thank the Medical Society for that privilege. In this study of bills and those who introduced the bills and the proponents as well as the opponents, human nature is seen at its best and at its worst; in the raw and adorned. People are asking for favors, even requesting that a bill be passed to create a special job for a favorite or a relative, to except or exempt one or more persons from certain provisions of the law—without regard for the welfare of the majority; and there are those who are willing to grant these favors. We recognize that some of the people want to be fooled. They have no desire to seek advice, even without cost, from expert sources; hence there is always room for the illegitimate trades as well as for the legitimate. Why crown the charlatans and quacks? You may interpret this either way. Certain practices are immoral and reprehensible and every avenue of penalty should be provided, while every avenue of escape should be closed. Yes, extensive rackets would be stopped if there would be tremendous losses of revenue. So a

sort of tabling act occurs—good bills are not passed or they die in committees. The public wants something novel. It is not enough that smallpox and tuberculosis, pneumonia and malaria, diphtheria and typhoid, yellow fever and other diseases are nearly stamped out, because of the worthwhile, conscientious, and scientific actions of the medical profession—this translated into terms of money means a greatly lowered income for physicians and a greatly enhanced health for the people. The public has frequently been told that fact, but why should they trust the physician? The canny legislator realizes that the public does not know what is good for it and in an open letter to physicians dares to say, "If I cannot secure such support (medical) I can only conclude that the medical profession is concerned merely with the competitive angle of the chiropractor's work and not with the public interest and welfare."

Some bills have already gone to the Governor for action, and we are certain they will be properly handled. The Governor has deserved the favorable comments and approval of the medical profession.

The *radiology* bill is in good hands. Interested parties have given an excellent account of themselves. The doctors have supported it loyally and the legislators are better advised than ever before. If the laboratories, the chiropractors, and certain labor interests win, we may deduce that the correct preparation of the patient for x-ray pictures or treatment, that the skillful taking of the pictures or giving of the treatments, and the correct and proper diagnoses of the cases mean less to these legislators than pleasing the above-mentioned groups.

The *optometrists* have been out in front with three bills. One bill, S. Int. 1098, passed through the labor committee of the Senate and on to the floor of the Senate so rapidly that it evoked the criticism of the legislative committee by several of the ophthalmologists, but fortunately it was killed in the Assembly labor committee. Our Council Advisory Committee composed of Drs. Berens, Marlow, Thomas Johnson, Snell, and Cowper have given us promptly their opinions and have done their part to oppose undesirable legislation.

The Governor vetoed the bills permitting attorneys for claimant in *Workmen's Compensation* cases to issue subpoenas. We are grateful.

The *Medical Grievance Committee* bills of the Regents, we feel, detract from the value of that special committee; whereas the bills originating in the State Medical Society and approved by the majority of the Medical Grievance Committee should work out satisfactorily. The bills by the State Medical Society have passed the Assembly and are up for Senate action. Neither House has taken action on the Regents' bills.

War necessity and chauvinism have claimed much attention. The *chiropractors* are trying to find an entering wedge into the army with Labor apparently giving almost unbelievable support to them in several well-known ways.

Now for the encomiums—bouquets or cor-sages. Our grateful thanks go to our president, Colonel Kopetzky, and to the other officers, to the Council, and to the county legislative com-

mittees, to the woman's auxiliaries, and to many others for their generous assistance and ready support. We wish to express our sincere appreciation to the legislators and to their officers—especially to Governor Lehman—for their constant, daily, kind consideration and cheerful reception of the medical profession and their medical public health problems. May we re-

quest the House of Delegates to adopt a suitable expression of appreciation.

The following is a statement of the standing of the bills we have studied up to April 21, 1942.

Respectfully submitted,

WALTER W. MOTT, M.D.
LEO P. SIMPSON, M.D.
JOHN L. BAUER, M.D.

Addendum Report

(April 25, 1942)

The Legislature adjourned a few hours later than prearranged, on Friday evening, April 24.

The final business of the Assembly was an attempt on the part of Mr. Brees to compel the Committee on Rules to report out the chiropractic bill. He made an impassioned address on the merits of chiropractic and the wisdom of the State's providing for a method of licensing its practitioners. At the close of his address he demanded that his request be acceded to. The Chamber denied his request. In the Senate, the Education Committee at noon the day before had conferred with regard to reporting the bill out and, I am informed, agreed that if the bill should pass the Assembly, they would report it out on the Senate floor. Thursday evening, after receiving the report of the Senate committee's decision, the county chairmen of the largest counties, and especially those where the attitude of the Senator was not too well established, were reached by long-distance telephone and re-

quested to communicate with their Senators immediately.

The Milmo Medical Grievance Committee bill, which is the bill of last year amended so as to meet the objections on which the Governor based his veto, having passed the Assembly, was defeated in the Senate. The opposition was presented by Senator Page, of Binghamton, based on a brief he exhibited and excerpts of which he read, submitted by Dr. Mazzola, a member of the Grievance Committee. After the vote was taken, Senator Young asked that the bill be tabled and, in the meantime, we explained to the dissenting Senators that the bill was endorsed by both the Medical and the Osteopathic societies and was practically the bill that the Grievance Committee itself drafted the year before with the Regents' approval. And then it was discovered that the opponents generally thought that the Society was opposed to the bill and the brief that Senator Page offered was an approval. This matter having been straightened out in their minds, the bill was brought out on the floor again and passed with no opposition.

The Senate before adjournment passed another bill which amends the Penal Law relative to the commission of abortion. The woman involved is thus permitted to offer evidence without incriminating herself. It is hoped that this will give the police and other enforcement officers a better opportunity to apprehend and convict commercial abortionists.

The X-ray bill reached third reading in the Assembly, but the powerful opposition which it encountered all the way along prevented its getting any further. However, Assemblyman Sullivan and I have learned a lot which we consider will be of great assistance in handling the bill next year.

A preliminary report of the bills acted upon in the last two days follows:

S. Int. 1032	Optometrists, testimony	To Governor
S. Int. 1424	Physicians, Civil Service positions	To Governor
S. Int. 1602	Students, athletic games,	To Governor

S. Int. 1681		
A. Int. 2037	Medical Grievance Committee	To Governor
S. Int. 1692		

JOSEPH S. LAWRENCE, *Executive Officer*

SPEAKER BAUER: This is referred to the Reference Committee on Report of the Council, Part VII, Dr. Walter P. Anderson, chairman, without reading, but as distributed to the delegates.

SECRETARY IRVING: There is also a supplementary report from the treasurer.

SPEAKER BAUER: Has that been distributed also?

SECRETARY IRVING: It has, sir, but I think it would be well if it were read. It is short.

Section 7. (See 46)

Supplementary Report of the Treasurer

DR. KIRBY DWIGHT: I have tried to make this as brief as possible.

As a supplementary report of the treasurer, I wish to submit an amendment to the Bylaws.

This amendment is proposed in order to facilitate the work of the treasurer's office and the activities of the Society. The Trustees meet regularly only once every two months during most of the year and not at all in midsummer. It is obviously a hardship for the officers, Council members, delegates to the American Medical Association, presidents of district branches, etc.,

to have to wait so long before they can be reimbursed for their expenditures. And it is a hardship that seems unnecessary to impose upon them, as these items of expense are all provided for in the budget.

Proposed Amendment to Chapter X of the Bylaws, Which Is Entitled "Expenses"

Delete the following phrases that have to do with approval of expense vouchers by the Board of Trustees before payment.

1. In the sentence reading "Proper vouchers must be filed with the Secretary . . ." delete the following:

"and approved by the Board of Trustees."

2. Delete the sentence reading:

"The vouchers of such expense shall be approved by the Board of Trustees before payment."

3. In the seventh line above the end of the section, as printed in the 1941 printing of Constitution and Bylaws, delete the phrase:

"and approved by the Board of Trustees."

Add at the end of the section the following sentence:

"Payment of all these expenses shall be made under directions of the Board of Trustees."

With these deletions and this addition, Chapter X as amended will then read:

Chapter X—Expenses

"Section 1. Allowances for expenses incurred in the actual performance of official duties by officers, members of the Council, the Board of Trustees, of the Board of Censors and committees, and delegates to the American Medical Association shall be made in conformity with the following conditions: The President shall be allowed a per diem and expenses when engaged upon official business. All other officers shall be allowed traveling expenses when engaged upon official business. Members of the Council, of the Board of Trustees and of the Board of Censors, shall be allowed traveling expenses. Members of committees of the Council, and all special committees of the Society, shall be allowed traveling expenses. Presidents of the District Branches sitting in the House of Delegates shall be allowed necessary expenses. There shall be no allowance made for the expenses, traveling or otherwise, for any committee appointed pursuant to Chapter XI of these Bylaws. Proper vouchers must be filed with the secretary before any of the above allowances are made. The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the secretary evidence of such attendance shall be allowed the actual cost of railroad transportation and Pullman accommodations to the place of meeting and return. Each district branch shall be entitled to receive a sum not to exceed \$200, exclusive of the work done by the secretary regarding notices, programs, etc., to defray the expenses of holding the annual meeting of such district branch, provided a proper state-

ment of such expense shall have been presented to the secretary. All bills, claims, or vouchers herein provided for shall be filed within thirty days after the date of the incurring of such expense. This time may be extended for any cause by the Board of Trustees and such extension shall not exceed ninety days. *Payment of all these expenses shall be made under directions of the Board of Trustees "*

It is now possible to estimate with some degree of accuracy the extent to which our Society will suffer financially from the loss of the dues of our members who are in active service in the Armed Forces of the United States. By the end of this year there will be about 2,500 of our members so engaged; this will mean a diminution in our income of about \$25,000 for the year 1943.

It is evident that the utmost economy must be practiced in the conduct of our Society. It is also evident that the income from our investments will have to be used to defray current expenses, instead of being saved in order to improve our financial position as they have been for the past few years. It is probable that there will have to be some curtailment of services or activities, and in this connection I should like to endorse the recommendation of the Council that the publication of the *Directory* be postponed. However, rather than seriously to curtail any of our essential activities or to disrupt our organization, I should favor selling some of our securities to meet the needs. The Society is to be congratulated on having had the good fortune and the foresight, in good times, to build up a very substantial war chest for use in just such an emergency as that in which we now find ourselves.

Respectfully submitted,

KIRBY DWIGHT, *Treasurer*

SPEAKER BAUER: That portion of the treasurer's Supplementary Report which pertains to the Bylaws will remain on the table in the hands of the secretary until next year, the balance of the report is referred to the Reference Committee on Report of the Treasurer and Board of Trustees, Dr. William Klein, of Bronx, chairman.

SECRETARY IRVING: The next supplementary report is from the Council, prepared by myself after the last meeting on March 12, 1942. It is short, so, although it has been distributed, I will read it.

Section 8. (See 47)

Supplementary Report of the Council—Part III: School Health Program

April 7, 1942

The Council at its meeting on March 12, 1942, received a report from Dr. Mitchell, as chairman of the Council Committee on Public Health and Education, on the subject of adding one hour to each school day for physical education activities. The Board of Education had recommended the added hour, on February 20, 1942. On March 6, 1942, at the request of the president of the New York State Association of School Physicians, Dr. Wm. E. Ayling, a combined meeting was held between Dr. Mitchell's Subcommittee on School Health Program and the Executive Committee

of the State Association of School Physicians. There were present at that meeting the following representatives of the two organizations:

New York State Association of School Physicians

Dr. William E. Ayling, president
Dr. Edgar Bieber, vice-president
Dr. C. Adele Brown, secretary-treasurer
Executive Committee:
Dr. Clarence A. Greenleaf
Dr. Lewis W. Heizer
Dr. Michael Levitan
Dr. John E. Burke

Medical Society of the State of New York

Dr. O. W. H. Mitchell, chairman, Council
Committee on Public Health and Education
Dr. Charles D. Post, Council Committee on
Public Health and Education
Dr. A. Clement Silverman, Subcommittee on
School Health Program
Dr. Albert D. Kaiser, Subcommittee on School
Health Program
Dr. J. G. Fred Hiss, chairman, Subcommittee
on 4-H Clubs, State Health Director National
Youth Administration

Dr. Mitchell reported to the Council that this matter had been discussed fully and that it had been decided to appoint Dr. Silverman of the State Society and Dr. Ayling of the State Association of School Physicians to draw up a letter to Dr. Mitchell which he could submit to the Council. The letter follows:

March 9 1942

Dr. O. W. H. Mitchell, Chairman
Council Committee on Public Health and Education,
Medical Society of the State of New York,
Syracuse, New York

Dear Dr. Mitchell

On March 6, the School Health Subcommittee of the Medical Society of the State of New York, and other representatives of the Society, met with the Executive Board of the New York State Association of School Physicians. The purpose of this conference was to consider the recommendation of the New York State Board of Regents, made at its meeting February 20, that an hour be added to each school day for physical education activities.

It is the opinion of the group that this plan will not bring about the results for which it is intended, i.e., to improve the physical fitness of school children. The report of the Board of Regents states that the problem of health and physical training has been made more acute in the public mind by current reports of the physical defects found by the draft.

Attention is called to the fact that, according to Col. L. G. Rowntree, Chief of the Medical Division of the Selective Service System, Washington, D. C., 45 per cent of those examined for military service were rejected for class 1-A. He states the main reasons for rejections were, first, teeth, then poor vision, heart disease, nutrition, mental and nervous diseases, ear conditions, herniae, and lung conditions. Very few, if any, of these conditions would be corrected, or even benefited, by the proposed extension of the physical education program. Muscle building sports and calisthenics will not do the job.

As Col. Rowntree says, an estimated 50 per cent of the rejectees have remediable defects which could be corrected by moderate, inexpensive, and comparatively safe medical and surgical procedure. Steps in this direction are already being taken, but there is definite need of this corrective medical work among our school chil-

dren, who will be our future service men. The school health services bring to the attention of the pupils, and their parents, the defects which are in need of correction, but parents and pupils often neglect to have these corrections made.

Private practitioners and school physicians are in favor of any measure which will improve the health of our youth, but this must start with the conditions which are known to be undermining their health. Exercise will help in a way and there is still the out of doors, where children can walk, ski, and skate in the winter, and swim and hike in the summer. These out-of-doors activities are greatly to be preferred over indoor drills and calisthenics.

Physicians are greatly concerned with childrens' health and feel that the school day is already long enough. They also feel that lengthening the time in school would tend to have a deleterious effect rather than promote good health.

We agree fully with the statement of the need of a more searching and far-reaching health program for the public schools. More adequate support of the School Health program would undoubtedly bring about corrections of defects found. What is needed is promotion of the Health Education and Health Service programs and not just the Physical Education activities. More instruction in personal hygiene, physiology, first aid, and, for girls, home nursing would be definitely of great benefit, particularly now while we are at war.

These facts may not all have been brought to the attention of the Board of Regents but should be considered before any radical change in the school program is made.

Respectfully submitted,

A CLEMENT SILVERMAN, M D
WM E AYLING, M D
Cochairmen

The Council directed the transmission of a copy of this communication to the Commissioner of Education and to each member of the Board of Regents. This instruction was carried out.

SPEAKER BAUER: This report is referred to the Reference Committee on Report of the Council, Part III, School Health Program, of which Dr. Leo F. Schiff, of Clinton, is chairman.

SECRETARY IRVING: The next supplementary report is from the Special Committee on Publication, which I think should be read by the chairman of that committee, Dr. Thomas M. Brennan.

DR. THOMAS M. BRENNAN: This also has been distributed, has it not?

SECRETARY IRVING: Yes.

(Dr. Brennan then read the following report.)

Section 9. (See 65)

Supplementary Report of the Council—Part XI: Committee on Publication

The Publication Committee begs to submit a substitution for that part of the Council Report—Part XI—which carries, under the subtitle "Continuation of Special Committees," the recommendation of the Council that the House direct the personnel be:

"For the Publication Committee the general manager, the director of the Public Relations Bureau, the literary editor, the treasurer, and one member of the Board of Trustees to be appointed by the president of the Society after

consultation with the chairman of the Board of Trustees, in accordance with the resolution adopted by the House of Delegates in 1941."

The Publication Committee recommends that the House give the following direction as to personnel:

"The Committee on Publication shall consist of the general manager, the treasurer, the director of the Public Relations Bureau, the literary editor, and one trustee, who shall be chairman; the trustee to serve shall be selected by the chairman of the Board of Trustees, and the literary editor shall be selected by the Committee on Publication at its first meeting after this meeting of the House of Delegates, the former literary editor not voting. This is deemed to be the most satisfactory way to choose the incumbent of this position, who thereupon becomes a member of the Committee, because of the familiarity of the Committee with the duties involved and the qualifications necessary for the satisfactory performance of them."

SPEAKER BAUER: This report is referred to the Reference Committee on Report of the Council, Part XI, of which Dr. Harry S. Bull, of Cayuga, is chairman.

SECRETARY IRVING: The next supplementary report, Mr. Speaker, is from the Special Committee on Office Administration and Policies. Although it has been distributed, I think it should be read by the chairman of the committee, Dr. Kosmak.

(Dr. George W. Kosmak read the following report.)

Section 10. (See 65)

Supplementary Report of the Council—Part XI: Committee on Office Administration and Policies

This Committee begs to add two recommendations to that part of the Council Report—Part XI—which carries, under the subtitle "Continuation of Special Committees," the recommendation for House direction as to personnel. After the paragraph headed "For the Committee on Office Administration and Policies" there would be added the following recommendations:

"That the Committee on Office Administration and Policies shall maintain a personnel file in which is a complete statement of the experience of every person on the clerical or administrative staff (other than persons under annual written contract with the Society), and in this file shall be reposed a full history—experience, salaries received, and places of employment—of each employee before entering the Society's employ, together with a statement of salary increases since entering such employ, changes of duties as they have occurred and may occur in the future. This shall also be required of applicants for position as well, on the usual blanks commonly used in administrative offices.

"That the Committee on Office Administration and Policies shall have power and authority to designate duties of members of the clerical staff, by this meaning all persons whose employment is otherwise than by written contract with the Society, and who are engaged

in secretarial, clerical, bookkeeping, editing, proofreading, or the supervision of such duties; to fix their salaries, to decide matters of overtime payment, and any and all other details of their work that the Committee may wish to delineate. No person shall be increased in salary and no new person be employed without the approval of this Committee, excepting temporary employees whose position on the staff shall not become permanent until authority has been obtained from the Committee."

SPEAKER BAUER: This report is also referred to the Reference Committee on Report of the Council, Part XI, of which Dr. Bull is chairman. Are there any further supplementary reports?

SECRETARY IRVING: No, sir.

Section 11

Introduction of Delegates from Other State Medical Societies

SPEAKER BAUER: Are there any delegates present from the Medical Societies of the States of Connecticut, New Jersey, or Vermont?

(There was no response.)

SPEAKER BAUER: If at any time you discover there are delegates present from those state societies, I wish you would inform the chair so that they may be properly recognized.

Section 12

Announcements by Speaker

Before we receive resolutions, there is one matter I should like to call to your attention. You will recall that last year you amended the Bylaws so as to eliminate the necessity for having an evening session on Monday. Heretofore we have had three sessions on Monday, with the result that everyone has been very much fatigued by the end of the evening. The amendment last year made it possible to eliminate this evening session by providing for two sessions on Monday and two on Tuesday. Therefore, for the first time the election of officers will not occur on Tuesday morning but will occur on Tuesday afternoon. It is important, gentlemen, that you be on time at the adjourned sessions of the House. The schedule of the sessions was announced in the JOURNAL a month ago, and I am sure you are familiar with it, but we will recess after this morning's session until 3:00 P.M. That afternoon session will probably run until 6:00 P.M., or maybe 6:30 P.M. because we must get as much done as possible today. Then we will recess until 9:00 A.M. tomorrow, Tuesday morning. I know that is an early hour, but it is necessary that we start promptly at 9:00 A.M. so as to complete all the business except the election in the morning session. The afternoon session will have to start promptly at 1:00 P.M. and we must be out of this room before 3:00 P.M., when a general session takes place.

I should also like to call your attention to the exhibits, not only to the Scientific Exhibits but to the Technical Exhibits. As you know, the success financially of an Annual Meeting of this Society depends in large part on our Technical Exhibits, and I hope that every gentleman of the House will show his appreciation of the technical exhibitors by going to their exhibits and showing

some interest in them. I hope that at the end of each session of the House you will all go out and spend some time going through these exhibits.

Section 13

Constitution and Bylaws—Amendments Adopted

SPEAKER BAUER: There are two amendments to the Constitution and Bylaws which were introduced last year. As they are both very brief they will be taken up at this point, and I will ask the secretary to read them.

(A) Amendment to Article IV of the Constitution

SECRETARY IRVING: The first amendment submitted last year, gentlemen, reads as follows:

"The first is a proposed amendment to Article IV of the Constitution, which reads:

'There shall be a Council composed of the president, the president-elect, the immediate past-president, the secretary, the treasurer, the speaker, and nine other members elected by the House of Delegates.'

"The proposed amendment is to insert after the word 'speaker' the words 'chairman of the Board of Trustees' so that as amended it will read:

'Article IV—Council

'There shall be a Council composed of the president, the president-elect, the immediate past-president, the secretary, the treasurer, the speaker, the chairman of the Board of Trustees, and nine other members elected by the House of Delegates.'

SPEAKER BAUER: I believe the amendment is perfectly plain. It simply modifies the present Constitution to make an additional member of the Council, namely, the chairman of the Board of Trustees. This amendment is before you for your consideration.

DR. GEORGE W. KOSMAK, New York: I move the adoption of this amendment to the Constitution.

DR. JAMES R. REULING, JR., Queens: I second the motion.

.... There being no discussion, the motion was put to a vote, and was unanimously adopted.....

(B) Amendment to Chapter VII of the Bylaws

SECRETARY IRVING: The second amendment proposed is to Chapter VII of the Bylaws, to be Section 13, as follows:

"Any officer of the Medical Society of the State of New York or its district branches who is called into active service with the Armed Forces of the United States, may, upon application to the Council, be granted leave of absence for any portion of his term of office during which he is on active service. During such absence, his duties shall be delegated as the Council may direct except where such delegation is already provided for elsewhere in the Bylaws."

SPEAKER BAUER: You will recall, gentlemen, that this was introduced last year as a resolution, if my memory serves me rightly, by Dr. Heyl, of Westchester, and was ruled out of order as a resolution. Inasmuch as it involved an amendment to the Bylaws, it had to remain on the table until this year. It is now before you for

consideration. As you know, except in those instances where the Bylaws specifically provide for the filling of an office during the absence of the incumbent, there is nothing that an incumbent can do except resign if he is away from his duties. It was felt that the military situation should not interfere with a man's remaining in office, and that was why this amendment was introduced and is before you for consideration as to whether or not you wish to provide that in the case of an officer being called into active military service he shall not have to resign his office, but that his place shall be filled by the Council until such time as he returns to take up his duties.

DR. ALFRED HELLMAN, *New York*: I move the adoption of that amendment to the Bylaws.

DR. KIRBY DWIGHT, *New York*: I second it.

.... There being no discussion, the motion was put to a vote, and was unanimously adopted....

SPEAKER BAUER: Are those all the amendments, Mr. Secretary?

SECRETARY IRVING: Yes.

SPEAKER BAUER: The Chair will now receive resolutions.

DR. GEORGE W. KOSMAK, *New York*: These are no resolutions, but they are amendments to the Constitution and Bylaws.

SPEAKER BAUER: Very well; we will take those now.

Section 14

Constitution and Bylaws—Proposed Amendments

DR. KOSMAK: Mr. Speaker and Members of the House, I desire to submit the following amendments to the Constitution and Bylaws of the State Society:

Article XIV Medical Benevolence Fund

"There shall be created a Benevolence Fund under the terms and conditions outlined in Chapter XII, Article 4, of the Bylaws. For this purpose there shall be appropriated by the Trustees out of the funds of the Society a sum not to exceed fifty cents per active member per year, to be set aside by the Treasurer as a special fund for the purpose of this Article. This fund shall be kept separate and invested or distributed by direction of the Board of Trustees of the Society under rules and regulations approved by the latter. The fund shall be used only for the relief of pecuniary distress of sick or aged members who are or have been active members in good standing of the Society."

Chapter XII, Section 4 Special Committees

"Section 4—The President of the Society shall appoint, immediately after the Annual Meeting, a special committee of five to be known as the Special Committee on Benevolence of the Medical Society of the State of New York, consisting of two members from the Board of Trustees to be selected by the Chairman of the latter, the Treasurer, the Secretary, and a representative from the Woman's Auxiliary of the State Society to be selected by its President. This Committee shall select its own Chairman and have absolute jurisdiction over the distribution of such funds as have been allotted

by the Society's Finance Committee from current income after appropriation by the Board of Trustees. No moneys shall be paid except on warrants signed by the Chairman of the Committee and the Treasurer. The Committee shall formulate rules and regulations for the acceptance of beneficiaries for consideration and approval by the Council. It may solicit subscriptions, donations, and legacies to be added to the principal of the Benevolence Fund. It shall present a detailed audit of receipts and expenditures, included in an annual report of its activities to the Council and the House of Delegates."

SPEAKER BAUER: In accordance with the Constitution and Bylaws, these proposed amendments must remain in the hands of the secretary until next year for consideration.

Are there any resolutions?

Section 15. (See 39)

Medical Expense Indemnity Insurance

DR. ABRAHAM KOPLOWITZ, *Kings*: This concerns Medical Insurance, and reads:

"WHEREAS, the Insurance Law, in Article IX-C, provides for voluntary nonprofit cash indemnity insurance and (through representations made on behalf of the Medical Society of the State of New York) the law now provides that no corporation shall be licensed to furnish both hospital and medical insurance; and

"WHEREAS, the Hampton-Wright bill introduced in the present session of the legislature would permit hospital service insurance plans to include indemnity for physicians and surgeons fees in their contracts; and

"WHEREAS, any medical indemnity furnished through a hospital insurance contract would make the service of doctors incidental to the institutional services with control of all details of such indemnity and service in the hands of lay dominated boards of management; and

"WHEREAS, the Hampton-Wright bill has been put off to the next session of the legislature with due notice that it will be pressed for favorable consideration if by that time medical insurance under administrative control of the medical profession has not developed a reasonably satisfactory participation on the part of both the profession and the public; and

"WHEREAS, the relatively small enrollment of subscribers and the incomplete participation of the medical profession during the past year have been due in part to the lack of outright full support of such enterprises by the organized medical societies; and

"WHEREAS, the Hampton-Wright bill, if enacted, will give the hospitals a legal entry into the practice of medicine, which in turn will constitute a long step toward lay control of medical practice and ultimately to a system of government medical service in the hands of a bureaucracy; and

"WHEREAS, The Council of the Medical Society of the State of New York has '... recognized with satisfaction the creation of three organizations for nonprofit medical expense indemnity insurance. In the opinion of the Council, the three have followed the tentative basis and suggestions for medical expense in-

demnity insurance that were set up by the House of Delegates, April 24, 1939'; therefore be it

"Resolved, that the Medical Society of the State of New York now officially approve, sponsor, and support in every manner possible the three corporations which have conformed to the principles prescribed by organized medicine for the protection of the interests of both the public and the profession in the organization and operation of medical insurance, namely: The Western New York Medical Plan, Inc., of Buffalo; the Medical and Surgical Care, Inc., of Utica; and the Medical Expense Fund of New York, Inc., of Brooklyn; and be it further

"Resolved, that notice of this action of the House of Delegates be given to the county medical societies within the territory of the organizations thus endorsed, and that each one be urged to cooperate in every practical manner toward the accomplishment of a successful operation of a

demnity insurance in their respective fields of influence and interest, in order that a system of medical insurance under administrative control of the medical profession shall be developed and maintained."

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business A, of which Dr. Simpson is chairman.

Section 16. (See 49)

Medical Relief, Direct Payment of Medical Fees

DR. KOPLOWITZ: I have another resolution which reads:

"WHEREAS, under the Social Security Act payments for medical care given to recipients-of-aid from the Blind, Old Age, and Dependent Children's divisions of the Department of Social Welfare can no longer be made to physicians directly, but, instead, these payments must be made to the patient; and

"WHEREAS, this method of payment has worked a hardship on the physicians who have rendered medical care to these persons by forcing them to make one or more additional calls to collect their bills; and

"WHEREAS, in New York City it has been proven that nearly 5 per cent of these patients have not paid their doctors for medical care rendered with the money which the State Department of Social Welfare gave them, but instead have spent the money for other uses; and

"WHEREAS, we are informed by the New York City Department of Welfare that this percentage is only a fraction of the number of patients who did not pay their physicians for medical care, as shown by the great many complaints from physicians who have telephoned to that department, rather than written letters which could be submitted in evidence; and

"WHEREAS, a similar resolution was introduced into the House of Delegates of the Medical Society of the State of New York at Buffalo, in 1941, at which time it was agreed that the State Society would carefully watch the experiment of using this method of payment; and

"WHEREAS, we feel that in New York City

this experiment has not been a success; therefore be it

"Resolved, that the New York State Medical Society, through its Delegates to the American Medical Association, request that the American Medical Association have legislation initiated to provide a change in the Social Security Act so that persons rendering medical care to recipients-of-aid from any government agency may be paid directly by that agency."

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business B, of which Dr. Masterson is chairman.

Section 17. (See 41, 42)

Opposition to Attempts to Lower Standing of Medical Practice or Conduct

DR. ARTHUR J. BEDELL, *Past-President*: I have this resolution to offer:

"WHEREAS, it has come to our attention that resolutions may be introduced in the House of Delegates of the American Medical Association which we believe will lower the ethical standing of the members of the profession; and

"WHEREAS, we are convinced that any attempt to so alter the professional standing of our members would be detrimental to the public health; be it therefore

"Resolved, that the House of Delegates of the Medical Society of the State of New York, in annual session assembled, hereby registers its protest of any such contemplated changes; and further be it

"Resolved, that the delegates from the Medical Society of the State of New York to the American Medical Association be instructed to oppose any and every attempt to lower the standing of medical practice or conduct."

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business C, of which Dr. Guess is chairman.

Section 18. (See 42)

Opposition to Change in A. M. A. Rule of Ethics Against Consultation with Nonmedical Persons

SPEAKER BAUER: The secretary has one resolution to read which was sent in by mail.

SECRETARY IRVING: This resolution comes from Dr. Irl H. Blaisdell, secretary, Syracuse Eye, Ear, Nose, and Throat Club:

"WHEREAS, there is a Rule of Ethics governing the relationship of members of the American Medical Association in the matter of giving lectures or courses of instruction or to consult with anyone not associated with actual medical service, adopted by the House of Delegates of the American Medical Association in 1935; and

"WHEREAS, this Rule of Ethics in the opinion of this organization is still satisfactory and adequate; and

"WHEREAS, the motion passed at the 1941 meeting of the Section of Ophthalmology of the American Medical Association, in Cleveland, asking the House of Delegates to rescind this motion was not adequately discussed; and

"WHEREAS, the one hundred and fifty members present did not fully represent the opinions of this organization; be it

"Resolved, that it is the opinion of this organization, the Syracuse Eye, Ear, Nose, and Throat Club, that the Rule of Ethics established in 1935 by vote of the House of Delegates not be rescinded; and be it further

"Resolved, that the Secretary be instructed to convey a copy of these resolutions to the Delegates of the New York State Medical Society, to the House of Delegates of the American Medical Association, and to such others as may be advisable, namely, the President of the American Academy of Ophthalmology, Dr. Ralph I. Lloyd, of Brooklyn, New York, and the Secretary of the Ophthalmological Section of the American Medical Association, Dr. Derrick Vail, of Cincinnati, Ohio."

SPEAKER BAUER: Inasmuch as this is on the same general topic as the resolution introduced by Dr. Bedell, it will be referred to the same Reference Committee, the Reference Committee on New Business C, of which Dr. Guess is chairman.

Section 19. (See 50)

Medical Relief, Direct Payment of Medical Fees to the Aged, the Blind, and Dependent Children

DR. WILLIAM TRAVIS GIBB, JR., *New York*: This is a similar resolution to that introduced a short while ago concerning the payment of physicians for medical care to the aged, the blind, and dependent children:

"WHEREAS, after April 1, 1941, checks from the Department of Welfare of the City of New York (Q. V. Form M. med 383 b) for the Medical Care of those patients entitled to Old Age Assistance and Blind Assistance will be issued directly to the recipients of the care and not to the doctors rendering it; and

"WHEREAS, this is patently unjust as it forces the physician to collect these fees from indigent people who may be unreliable; and

"WHEREAS, this is an example of the unfair advantages being taken of physicians; therefore be it

"Resolved, that the Medical Society of the County of New York go on record as being opposed to the proposed change in method of payment; and that the Society request the Department of Welfare to continue its former method of paying these physicians directly; and be it further

"Resolved, that this House of Delegates be instructed to vigorously protest this injustice, to record itself as being opposed to this procedure; and to have the Medical Society of the State of New York also request the Department of Welfare to pay those physicians directly, as heretofore; and be it also

"Resolved, that the Medical Society of the State of New York recommend to the American Medical Association to request the Government at Washington to alter that provision of the Social Security Law necessary to permit doctors to be paid directly."

SPEAKER BAUER: This resolution will be referred to the same Reference Committee as the previous one, namely, the Reference Committee on New Business B, of which Dr. Masterson is the chairman.

Section 20. (See 86)

Elimination of Required Certification of Checks in Payment of Tax Stamps for Opium Dispensing, etc.

DR. WALTER P. ANDERTON, *New York*: This resolution is introduced under the instructions of the Medical Society of the County of New York:

"WHEREAS, the physicians and surgeons who dispense or prescribe opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required by Federal law and regulations annually to purchase a special tax stamp for \$1.00; and

"WHEREAS, when payment of such dollar is made by check, it is required that such check be certified by the bank of payment; and

"WHEREAS, the Treasury Department of the United States of America accepts checks for larger amounts without requiring certification; therefore be it

"Resolved, that the Medical Society of the State of New York protests against the requirement that checks for purchase of special tax stamps in connection with dispensing and prescribing opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required to be certified; and be it further

"Resolved, that the delegates from the Medical Society of the State of New York to the House of Delegates of the American Medical Association are hereby instructed to introduce a resolution at the 1942 session embodying this protest, and urging the American Medical Association to take emphatic and persistent steps toward the elimination of the requirement for certification of checks previously mentioned in this resolution; and be it further

"Resolved, that copies of this resolution be sent to important local and national dentist, veterinary, pharmacist, manufacturing chemist, and banker organizations, inasmuch as members of such organizations are also affected by the unnecessary labor of certification of small checks."

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business A, of which Dr. Simpson is the chairman.

Section 21. (See 66)

"Walk a Block a Day"

DR. HARRY C. GUESS, *Erie*: This resolution was passed unanimously by the Erie County Medical Society:

"WHEREAS, the Medical Society of the County of Erie has passed resolutions advocating that walking a block a day is a good health measure; and

"WHEREAS, it is the duty of the medical profession to promulgate health measures for all people; and

"WHEREAS, there is great need, especially during these times, for better health and a stronger nation; and

"WHEREAS, it is possible for each component county society comprising the New York State Medical Society to advocate this health measure; therefore be it

"Resolved, that the Delegates of this New York State Medical Society approve this health project; and be it

"Resolved, that the Public Health Committee of the Council formulate plans to bring this slogan,

'WALK A BLOCK A DAY'

before the public; and be it further

"Resolved, that our Delegates to the A.M.A. present as a resolution to the Delegates at Atlantic City in June to recommend this health measure to the people of the United States, using the slogan:

'WALK A BLOCK A DAY.'

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business B, of which Dr. Masterson is chairman.

Section 22. (See 44)

Licensure, Full Citizenship Requirement

DR. JOHN L. EDWARDS, Columbia: This resolution is introduced on behalf of Dr. Denver M. Vickers, of Washington County, Dr. Joseph H. Cornell, of Schenectady County, and myself:

"... of foreign-educated medicine in this state without known scholastic and medical training has tended to lower the standards of medical ethics and practice, be it

"Resolved, that applicants for the practice of medicine in this state from foreign schools other than Canada be required to have full citizenship, premedical and medical education comparable with that of class A medical schools of the United States and Canada."
(Applause)

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

Section 23. (See 35)

Waiving of Penalties for Failure to Attend Hospital Staff Meetings

DR. HAROLD B. DAVIDSON, New York: This resolution reads:

"WHEREAS, the duties of physicians working in hospitals will increase greatly during the war, therefore be it

"Resolved, that the American Medical Association, the American College of Surgeons, and other national organizations be petitioned to waive penalties to hospitals or doctors for failure to attend staff meetings in hospitals for the duration of the war and six months thereafter.

"On motion, this resolution was passed, and it was voted to refer the matter to the Coordinating Council and to instruct the Delegates of the Medical Society of the County of New York to introduce this resolution at the next meeting of the House of Delegates of the Medical Society of the State of New York."

SPEAKER BAUER: This is referred to the Reference Committee on New Business A, of which Dr. Simpson is the chairman.

Section 24. (See 43)

Foreign Physicians Under Procurement and Assignment

DR. JOHN D. CARROLL, Rensselaer: At a recent meeting of the Medical Society of the County of Rensselaer we were given instructions to present this resolution:

"Resolved, that the Delegates representing the Medical Society of the County of Rensselaer of the State of New York put forward this resolution:

"Pursuant to Surgeon General Parran's editorial of recent date in the *Journal of the American Medical Association*, concerning the shortage of medical practitioners throughout the country and advocating the lessening of licensure restrictions in the case of foreign physicians, we of the Medical Society of the County of Rensselaer respectfully submit:

"Resolved, that (1) since the majority of said foreign doctors are engaged in the practice of medicine in the State of New York, the Office of Procurement and Assignment shall in the future select from among these same foreign doctors now practicing in this state physicians for practice in other states that meet with New York State's reciprocity laws;

"(2) All foreign physicians who have been licensed to practice in the United States be brought under the jurisdiction of the Procurement and Assignment Board, and, if they are not eligible for Army or Navy duty, they shall be placed in other governmental service for the duration of the war."
(Applause)

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman, which has another resolution on the same subject.

Section 25. (See 40)

Connecticut State Medical Society, 150th Anniversary

DR. BENJAMIN M. BERNSTEIN, Kings: This resolution was unanimously passed by the Medical Society of the County of Kings:

"WHEREAS, the Medical Society of the State of Connecticut is celebrating the 150th anniversary of its founding at Middletown, Connecticut, on June 3 and 4, 1942; and

"WHEREAS, friendly relations between neighboring states particularly should always be maintained; be it

"Resolved, therefore, that two delegates of the Medical Society of the State of New York be sent as representatives to the Convention of the Medical Society of the State of Connecticut on the above-mentioned dates in order to join with them in the celebration of their 150th anniversary."

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

Section 26. (See 37)

Women Physicians and the Medical Reserve Corps of the Army and Navy

DR. EMILY DUNNING BARRINGER, New York: This resolution was unanimously passed at the

"Resolved, that it is the opinion of this organization, the Syracuse Eye, Ear, Nose, and Throat Club, that the Rule of Ethics established in 1935 by vote of the House of Delegates not be rescinded; and be it further

"Resolved, that the Secretary be instructed to convey a copy of these resolutions to the Delegates of the New York State Medical Society, to the House of Delegates of the American Medical Association, and to such others as may be advisable, namely, the President of the American Academy of Ophthalmology, Dr. Ralph I. Lloyd, of Brooklyn, New York, and the Secretary of the Ophthalmological Section of the American Medical Association, Dr. Derrick Vail, of Cincinnati, Ohio."

SPEAKER BAUER: Inasmuch as this is on the same general topic as the resolution introduced by Dr. Bedell, it will be referred to the same Reference Committee, the Reference Committee on New Business C, of which Dr. Guess is chairman.

Section 19. (See 50)

Medical Relief, Direct Payment of Medical Fees to the Aged, the Blind, and Dependent Children

DR. WILLIAM TRAVIS GIBB, JR., *New York*: This is a similar resolution to that introduced a short while ago concerning the payment of physicians for medical care to the aged, the blind, and dependent children:

"WHEREAS, after April 1, 1941, checks from the Department of Welfare of the City of New York (Q. V. Form M. med 383 b) for the Medical Care of those patients entitled to Old Age Assistance and Blind Assistance will be issued directly to the recipients of the care and not to the doctors rendering it; and

"WHEREAS, this is patently unjust as it forces the physician to collect these fees from indigent people who may be unreliable; and

"WHEREAS, this is an example of the unfair advantages being taken of physicians; therefore be it

"Resolved, that the Medical Society of the County of New York go on record as being opposed to the proposed change in method of payment; and that the Society request the Department of Welfare to continue its former method of paying these physicians directly; and be it further

"Resolved, that this House of Delegates be instructed to vigorously protest this injustice, to record itself as being opposed to this procedure; and to have the Medical Society of the State of New York also request the Department of Welfare to pay those physicians directly, as heretofore; and be it also

"Resolved, that the Medical Society of the State of New York recommend to the American Medical Association to request the Government at Washington to alter that provision of the Social Security Law necessary to permit doctors to be paid directly."

SPEAKER BAUER: This resolution will be referred to the same Reference Committee as the previous one, namely, the Reference Committee on New Business B, of which Dr. Masterson is the chairman.

Section 20. (See 36)

Elimination of Required Certification of Checks in Payment of Tax Stamps for Opium Dispensing, etc.

DR. WALTER P. ANDERTON, *New York*: This resolution is introduced under the instructions of the Medical Society of the County of New York:

"WHEREAS, the physicians and surgeons who dispense or prescribe opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required by Federal law and regulations annually to purchase a special tax stamp for \$1.00; and

"WHEREAS, when payment of such dollar is made by check, it is required that such check be certified by the bank of payment; and

"WHEREAS, the Treasury Department of the United States of America accepts checks for larger amounts without requiring certification; therefore be it

"Resolved, that the Medical Society of the State of New York protests against the requirement that checks for purchase of special tax stamps in connection with dispensing and prescribing opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required to be certified; and be it further

"Resolved, that the delegates from the Medical Society of the State of New York to the House of Delegates of the American Medical Association are hereby instructed to introduce a resolution at the 1942 session embodying this protest, and urging the American Medical Association to take emphatic and persistent steps toward the elimination of the requirement for certification of checks previously mentioned in this resolution; and be it further

"Resolved, that copies of this resolution be sent to important local and national dentist, veterinary, pharmacist, manufacturing chemist, and banker organizations, inasmuch as members of such organizations are also affected by the unnecessary labor of certification of small checks."

SPEAKER BAUER: This resolution is referred to the Reference Committee on New Business A, of which Dr. Simpson is the chairman.

Section 21. (See 66)

"Walk a Block a Day"

DR. HARRY C. GUESS, *Erie*: This resolution was passed unanimously by the Erie County Medical Society:

"WHEREAS, the Medical Society of the County of Erie has passed resolutions advocating that walking a block a day is a good health measure; and

"WHEREAS, it is the duty of the medical profession to promulgate health measures for all people; and

"WHEREAS, there is great need, especially during these times, for better health and a stronger nation; and

"WHEREAS, it is possible for each component county society comprising the New York State Medical Society to advocate this health measure; therefore be it

SPEAKER BAUER This resolution will be referred to the Reference Committee on New Business A, of which Dr. Simpson is the chairman

Section 29. (See 48)

1943 Annual Meeting, Invitation to Buffalo

DR. GARTNER This is another resolution that was passed by the Medical Society of the County of Erie.

"WHEREAS, the 1941 Annual Meeting of the Medical Society of the State of New York was a great success in Buffalo; and

"WHEREAS, the President-elect, Dr. George W. Cottis, is a resident of Western New York; and

"WHEREAS, the Medical Society of the County of Erie would indeed deem it an honor and great pleasure to have its colleagues from the rest of the State meet in Buffalo; therefore be it

"Resolved, that the Medical Society of the County of Erie extend an invitation to the Medical Society of the State of New York to hold its 1943 Annual Meeting in Buffalo."

SPEAKER BAUER This resolution will be referred to the Reference Committee on New Business B, of which Dr. Masterson is the chairman

Are there any further resolutions?

(There was no response)

SPEAKER BAUER I ask you to bear in mind that you have adopted an amendment to the Bylaws providing that no resolution can be introduced in the final session except by authority of the House by a two-thirds vote. Furthermore, the final session will necessarily have to be as short as possible for, as I said earlier, we will have to be out of this room by three o'clock on Tuesday afternoon, so any of you who have resolutions please see that you have them ready to introduce either this afternoon or tomorrow morning, as they should not be introduced after that, except if a grave emergency arises.

If there are any reference committees that are short, due to the absence of their members, I wish they would see the secretary so that the vacancies may be filled.

The reference committees are meeting on the balcony, and, as I said before, I should like all officers and councilors to hold themselves in readiness to go before any reference committee that may desire their presence.

Please bear in mind what I said about the importance of visiting exhibits.

We will now take a recess until 3:00 P.M.

(At 11:30 A.M. a recess was taken)

Afternoon Session

April 27, 1942

The session convened at 3:10 P.M., pursuant to recess.

SPEAKER BAUER The House will be in order. Are there any reference committees ready to report?

Section 30 (See 4, 5)

Report of Reference Committee on Reports of President and President-Elect

DR. CARLTON E. WERTZ *Erie* The Committee on the Report of the President wishes to commend him for his splendid report and acknowledge his sacrificial devotion to his duty this past year. The Society surely owes him an expression of deepest gratitude for his splendid services. We believe, as he states that the time for talk and for discussion and argument is past. We must face facts.

His review of the activities of the Society and its numerous committees is timely, and we recommend that all of us familiarize ourselves with the reports as presented in the JOURNAL.

We feel that it is our duty to particularly call your attention to references in the report to the medical relief problem and the cooperation with the State Department of Social Welfare to the end that the best available care shall be given to both the indigent and the near-indigent.

We call your attention to the effort to break the legal expense of medical and hospital care and to the government's proposition to give medical and hospital care to its Social Security clients. We agree that deep study be given to these problems.

The financial problem of the remitting of dues

of those called to the service calls for a close scrutiny of the total expenses of the Society and that plans be made for a conservation wherever possible. We agree with the president when he says, "I would recommend the remission of dues to those physicians to whom, while in the service of their country with the Armed Forces, the payment of dues constitutes a burden and a hardship, and limit it to those that ask for it."

Part 2 of the report deals with trends in medical affairs and demands a most careful study by this Society. This is most timely, and we wish to earnestly call your attention to the problems set forth, such as:

A. The Federal Hospitalization Tax Program and its possible trend toward a system of state medicine.

B. The Federal Rehabilitation Program and its many trends toward state or federal medicine.

Your committee moves the adoption of this splendid report and recommends that attention to the pressing attention

DR. HERBERT B. SMITH, Steuben. I second the motion.

There being no discussion, the motion was put to a vote, and was unanimously carried.

SPEAKER BAUER Is that the full report of the committee?

DR. WERTZ No, I have reports on the supplementary address of the president and the address of the president-elect.

SPEAKER BAUER Proceed!

DR. WERTZ Reporting on the address of President Kopetzky to the House of Delegates the committee agrees with the thoughts expressed

last meeting of the Medical Society of the County of New York, on Monday evening, April 20, 1942:

"WHEREAS, during the past winter women physicians have been denied commissions in the Medical Reserve Corps of the United States Army, because of their sex, and in spite of outstanding personal and professional qualifications, as, for instance, in the case of a skilled anesthetist attached to a Base Hospital which was ordered into active service, and in this case the colonel in charge and the chief surgeon highly endorsed and desired that this woman be a member of the staff of this Base Hospital, and

"WHEREAS, during this past winter two American women physicians have received commissions in the Royal Army Medical Corps of the British Army, one as a Major and the other as a Lieutenant, and both have been assigned to military hospitals, and

"WHEREAS, the women physicians of the American Medical Association are a minority group, who, however, pay dues and take part in the activities of the Association, and turn to the Association for help in their problems of medical opportunities; and

"WHEREAS, there is no existing ruling that women are ineligible for the Medical Reserve Corps of the United States Army, while there is an existing ruling in the Navy, which could be removed by the proper authorities; and

"WHEREAS, at the last meeting of the House of Delegates of the Medical Society of the State of New York, the House went unanimously on record as approving that women physicians be admitted to the Medical Reserve Corps of the United States Army and Navy, and formally requested the American Medical Association to endorse their action, which was not accomplished; therefore be it

"Resolved, that the Delegates from New York County be instructed to ask the House of Delegates to go on record again this year, and ask the American Medical Association to aid one of its minority groups by endorsing and aiding women physicians in obtaining commissions in the Medical Reserve Corps of the United States Army and Navy."

I have just received, through Dr Ruth Ewing, the unanimous endorsement of this resolution by the Women's Medical Society of the State of New York at their executive session on Monday, April 27, 1942 (Applause)

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business A, of which Dr Simpson is the chairman

Section 27. (See 67)

Discrimination in Employment of Minority Racial Groups

DR PETER MURRAY, *New York* I wish to introduce the following resolution:

"WHEREAS, the President of the United States has issued an executive order requiring fair employment practices on the part of all business firms holding government contracts; and

"WHEREAS, in order to enforce this order he has established the Fair Employment Practice Committee; and

"WHEREAS, this committee investigates charges of discrimination in employment against minority racial groups; and

"WHEREAS, this committee has charged the Becton-Dickinson Company with violation of this executive order, in that said company refuses employment to certain racial groups; therefore be it

"Resolved, that the New York State Medical Society delete Becton-Dickinson advertisements from its publication; and be it further

"Resolved, that the Editor of the New York State Medical Journal be instructed to editorialize this unfair practice; and be it also further

"Resolved, that the New York State Medical Society urge its members to withhold patronage from said firm until its unfair practices shall have ceased."

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business B, of which Dr. Masterson is the chairman

Section 28. (See 38, 69)

Suggested New Subcommittee on Tuberculosis Control

DR. ALBERT A. GARTNER, *Erie* This is a resolution which the Medical Society of the County of Erie has instructed its delegates to introduce into this House.

"WHEREAS, the problem of tuberculosis control has never been attacked as intensively or as effectively as that of syphilis; and

"WHEREAS, the Commissioner of Health of the State of New York has recently instituted a campaign to eradicate tuberculosis from this State by the year 1960 and needs the combined efforts of the medical profession to insure the success of this project; and

"WHEREAS, tuberculosis is a highly contagious and yet preventable disease, and many possible sources from which it may be spread to healthy contacts are still existent; and

"WHEREAS, to effectively investigate these sources, such measures as routine tuberculin testing of older children, mass x-ray examination of those living in sections that have a high incidence of tuberculosis, routine (yearly) examination of food handlers, domestics, and school teachers, and more adequate care and supervision of the tuberculous and ex-tuberculous patient will be necessary; therefore be it

"Resolved, that an intensive educational program and campaign be instituted throughout the State under the auspices of the Medical Society of the State of New York to acquaint the general public and medical profession with the effective ways and means in the prevention and control of tuberculosis; and be it further

"Resolved, that a subcommittee on Tuberculosis Control to serve under the Council Committee of Public Health and Education or a separate committee be appointed; and be it further

"Resolved, that this Committee should cooperate with the Commissioner of Health and the various agencies interested in the problems of tuberculosis to institute such measures as will make this program effective, and that an offensive rather than a defensive campaign against the disease should be put into operation"

Council, Part II, desires to make the following report:

Under the heading *Chemotherapy Program*, your committee heartily endorses this portion of the report of the Council and urges continuation of this program.

Under the heading *Rheumatic Fever*, your committee endorses this program and also urges its continuance.

Under the heading of *Dental Health*, your reference committee urges continued study on the dental health program.

Under the heading *Industrial Health*, your committee endorses the work that has been done on this program, and, in view of the present emergency, we urge that this program be continued and expanded to meet the present needs.

Under the heading of *Maternal and Child Welfare*, your reference committee approves this portion of the report and also urges the continuation of the program.

Under the heading of *The 4-H Club and Youth Activities*, your committee approves the work done by Dr. Fred Hiss, chairman of the 4-H Club and Youth Activities, and urges the continuation of this work. Your committee is in accord with the plan of Dr. Hiss's committee to discard the old annual health contest because it has very little value.

Under the heading of *War Medicine and Surgery*, your reference committee approves and endorses the work done, and also wishes to add that under the direction of the Office of Civilian Defense, the Health Preparedness Commission of New York State, the State Health Department, the medical schools of New York State, and the Medical Society of New York State, this committee is planning to include in the activities of War Medicine and Surgery, emergency surgery, first-aid instructions, and chemical warfare instructions. Your reference committee feels that the addition of these latter groups of study are very necessary and essential at this particular time.

Under the heading *Venereal Disease Control*, your committee approves the recommendations as made.

Under the heading of *Tuberculosis Conference Committee*, your reference committee approves the report, and if you have the booklet in front of you, on page 639, of the April 1, 1942, reprint of the JOURNAL, you may follow me, for we desire to make a change in Part 7. In other words, your reference committee approves the report, except Parts 7 and 8. Part 7, as printed, reads:

"Patients, who, in the opinion of the health officer or his representative, for various reasons (contacts, etc.) should have a thorough physical examination including x-ray, as a part of the tuberculosis control program, should be rendered x-ray service without direct cost to themselves."

Your committee wishes to substitute for that the following:

"Only medically indigent patients or contacts referred by the family physician, who, in the opinion of the health officer or his representative, for various reasons (contacts, etc.) should have a thorough physical examination, including x-ray, as a part of the tuberculosis control program, should be rendered x-ray service without direct cost to themselves."

We should also like to amend Part 8 of the same report. At present it reads:

"All x-ray examinations at tuberculosis hospitals and clinics should be done without direct cost to the patients."

We should like to amend that to read as follows:

"All x-ray examinations at federal, state, or municipal hospitals should be done without direct cost to the patient."

SPEAKER BAUER: I think before we get any further we had better first approve certain portions of your report. The report so far has covered Chemotherapy, Rheumatic Fever, Dental Health, Industrial Health, Maternal and Child Welfare, 4-H Club and Youth Activities, War Medicine and Surgery, and Venereal Disease Control. Excluding the Tuberculosis Conference Committee, the report so far was merely approving what the Council committees had done and urging continuation of their efforts along the same lines. I suggest that you move the adoption of that portion of the report.

DR. DI NATALE: I so move.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: Now on the next section under Tuberculosis Conference Committee, the reference committee recommends two changes in Parts 7 and 8 of the Report. I think you might read those again, Dr. Di Natale, so that everybody will be clear as to what you mean.

DR. DI NATALE: Part 7 at present reads as follows:

"Patients, who, in the opinion of the health officer or his representative, for various reasons (contacts, etc.) should have a thorough physical examination, including x-ray, as a part of the tuberculosis control program, should be rendered x-ray service without direct cost to themselves."

Your committee would like to amend that to read as follows:

"Only medically indigent patients or contacts referred by the family physician, who, in the opinion of the health officer or his representative, for various reasons (contacts, etc.) should have a thorough physical examination, including x-ray, as a part of the tuberculosis control program, should be rendered x-ray service without direct cost to themselves."

I move the adoption of that substitution in the Council committee's report.

DR. ROBERT BRITAIN, Delaware: I second the motion.

SPEAKER BAUER: Is the motion clear? It amends the Council committee's report to provide that these examinations should be done without direct cost only on the recommendation of the family physician. Is there any discussion on that?

SECRETARY IRVING: It happens that I was the first representative of the State Society to sit on that Tuberculosis Conference Committee, and then Dr. Mitchell and Dr. Hambrook were later added. At the Council's request, we went over these things with great care. The reason that particular thing about indigency is not in it

so well and clearly, and would like to stress the fact that the Medical Society should be on guard so that any plans made now for the emergency should cease on demobilization.

We recommend that the president's remarks be printed in the JOURNAL, and I so move.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

DR. WERTZ: Reporting on the address of President-Elect Cottis to the House of Delegates, the committee gave due consideration to the discussion of Dr. George W. Cottis, the president-elect. His remarks were pertinent to the problems of the day, and we recommend that his talk be printed in the JOURNAL. I so move.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

DR. WERTZ: I now move that the report, as a whole, signed by the members of the committee, Herbert B. Smith, Stephen H. Curtis, J. Stanley Kenney, Dan Mellen, and Carlton E. Wertz, chairman, be adopted.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

Section 31

Report of Reference Committee on Report of the Council—Part I: Postgraduate Education

DR. ALBERT F. R. ANDRESEN, *Kings*: The report is clear and concise and describes the amazing amount of work that Dr. Mitchell and his committee have accomplished in the past year in the field of postgraduate education. The publication of the *Course Outline Book*, and its distribution to all county medical societies, has greatly facilitated the carrying out of the program. Collaboration with the State Departments of Health and Labor has resulted in official recognition of the postgraduate courses and has brought some financial assistance. Courses of lectures were arranged for in twenty-seven County Medical Societies, with an average of 5.6 lectures per course, and in twenty-two of these courses the Society received financial assistance from the State Health Department because the subjects taught coincided with those considered of particular importance in the State Health Program. Maternal and Child Welfare was particularly emphasized during the past year, and Teaching Days were conducted in seven cities covering "regions" of the State. Teaching Days in Cancer and in Public Health were also conducted, and a three-day Postgraduate Institute was held at Rochester. A subcommittee on War Medicine and Surgery has begun to function, and Dr. Mitchell has reported to this committee that in collaboration with the Office of Civilian Defense, the State Health Department, the Health Preparedness Committee of New York State Legislature, the medical schools of the State of New York, and the Medical Society of the State of New York, there will be available within a few weeks courses in Emergency Surgery and Chemical Warfare that will enable physicians to cope with these emergencies and to give satisfactory courses to laymen in these subjects. It is to be hoped that County Medical Societies will avail themselves of these educational opportunities.

The report of the committee contains a note that more of the Society's funds have been expended than previously, a fact that should be emphasized and of which our Society should be very proud, as the work of this committee is not only of the utmost value to the members of our Society, but also to the entire population of our state. The Council and Dr. Mitchell's committee should be congratulated and thanked for the excellent and efficient work that has been accomplished.

I move the adoption of the committee's report.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: Thank you, Dr. Andresen!

Section 32. (See 6)

Report of Reference Committee on Report of the Council—Part VII: Legislation

DR. WALTER P. ANDERTON, *New York*: Your Reference Committee on Legislation commends heartily to our membership the unflinching and industrious efforts of your Committee on Legislation during the past year, and the splendid accomplishments of Dr. Joseph Lawrence, the secretary of that committee. During the 1942 Session of the New York State Legislature, we regret to say the x-ray bill was defeated. This would have made the use of x-rays for diagnostic or therapeutic purposes illegal, except in the hand of a duly licensed member of our profession. However, the Milmo Medical Grievance Committee Bill was passed. This will improve the functioning of the Grievance Committee, it is hoped.

On the other side of the ledger, we find that the perennial chiropractors bill was defeated in spite of very strong efforts in its behalf; and that several bills that were supported by your Committee on Legislation, such as the ones relative to testimony in regard to criminal abortions, licensing nurses registry bureaus, and physicians in Civil Service positions, have been passed by both the Assembly and the Senate and are now awaiting action by the Governor.

We take this opportunity to draw attention to the intelligent and sympathetic attitude which Governor Lehman has always shown toward problems affecting the health of the people in this state.

This report is signed by the committee, consisting of Walter P. Anderton, chairman, Eugene H. Coon, B. Wallace Hamilton, Leo E. Reimann, and Moses A. Stivers, and I move the adoption of the committee's report.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

Section 33

Report of Reference Committee on Report of the Council—Part II: Public Health Activities, 4-H Club and Youth Activities, War Medicine and Surgery, Venereal Disease Control, Tuberculosis Conference Committee, Deaf and Hard of Hearing

DR. PETER J. DI NATALE, *Genesee*: Your Reference Committee on the Report of the

will find this feasible. However, the committee does not recommend any change in the quality of the present cover of the *JOURNAL*. The pertinent point is that the average cost of the *JOURNAL* to each member was 88 cents for 1941, as compared to 91 cents for 1940. It is your committee's opinion that the *JOURNAL* is one of the best investments made by any member of the Society.

The Publication Committee of the *Directory* has considered the cost and prospective revenue, and we think they are in the best position to judge about the immediate future publication of the *Directory*. Therefore, the reference committee feels that the opinion of the Council in the postponement temporarily of the publication of the *Directory* is a wise one. That it should not be too long delayed is likewise obvious, and the decision for its publication during this emergency would be most expediently considered from year to year by leaving the date of publication to the discretion of the Council. The *Directory* is one of the greatest practical aids to the physician of any available publication. How could we get along without it! Again, financially it is an excellent \$1.02 investment. Further, this cost is a saving over the previous volume, and all commendation is due to the Publication Committee.

SPEAKER BAUER: Inasmuch as your last recommendation involves an action which is different from that the House ordered a year ago, I think we should stop at that portion of your report and act on it before proceeding to the next subdivision.

DR. EGGSTON: I move the adoption of that portion of the reference committee's report.

DR. JAMES GREENOUGH, Olsego: I second the motion.

SPEAKER BAUER: This portion of the reference committee's report is before you for adoption. It includes a recommendation to postpone the publication of the *Directory*. The House originally directed that a *Directory* should come out this coming fall, and if the recommendation of the reference committee is adopted, it will necessarily delay such publication for a period of at least six months by action of the Council. If you approve of the recommendation of the reference committee, you will likewise approve of the action of the Council in delaying publication of the *Directory* because of the war situation. Is there any discussion?

DR. HARRY ARANOW, Bronx: Does that recommendation also encompass the thought that the Council, if it sees fit, can also delay the further publication of the *Directory*?

SPEAKER BAUER: Yes, it also recommends that the date of publication of the *Directory* be left to the Council in the immediate future.

Is there any further discussion on the motion?
 There were calls for the question, so the motion was put to a vote, and was carried. . . .

DR. EGGSTON: In regard to medical publicity both on the radio and in the newspapers, there were many interesting subjects discussed and special attention is called to the article, "The Role of the Doctors in Defense," by Colonel Samuel J. Kopetzky, as well as other valuable contributions by this author. It is unfortunate that the radio broadcast has to be discontinued or curtailed because of the cost and the lack of a satisfactory sponsor, and we trust some means will

be forthcoming to resume this service to the public.

In relation to newspapers, the committee urges a further cooperation with all the newspapers of the state for releases of accurate and timely editorials and discussion of medical subjects of public interest. Too much stress cannot be placed upon the value of such discussions. In fact, there should be a committee of physicians and editorial writers in each county of the state to cooperate as an editorial board for the release of medical information to the public. This would avoid much misunderstanding and the publication of wrong information about physicians and medical subjects. The committee knows of no better way to reach the public than through a perfect understanding with the newspapers.

Postgraduate medical education has received excellent stimulation and cooperation from the State Society in the past year under able leadership. The establishment of refresher courses upon timely subjects should be further extended to encourage every county of the state. There are wonderful institutions of medical teaching throughout the state that should continue to be encouraged to offer refresher courses to the members of the Society.

The committee likewise thinks that the issuance of bulletins of the club talk series type is to be commended and continued, as they have been quite popular and extremely useful. It would be of interest to know the number of these sent to members and the cost.

The results of the Public Relations Committees of our county, state, and national societies have been at best intangible and from a practical purpose, a disappointment. However, these efforts may have delayed compulsory health insurance. But in the face of it all, the profession stands convicted as a trust, with the future of medicine most uncertain. This is in spite of the earnest and unselfish efforts of the many conscientious men serving on these committees. Perhaps the very modesty of our profession prevents the use of more militant tactics to protect our economy. The accomplishments of the medical profession to influence the trends of medicine pale when compared to the gain of labor groups, who in the opinion of high authority have not always bothered much about public relations.

Influencing people and making friends by talking and propaganda is one thing, but after this global war, it is apparent that more direct and positive methods will be needed to safeguard medical care.

It seems that our relations to the public are like an earless boat drifting down the Niagara River, soon to drop over the falls of Socialized Medicine. At present, there is no anchorage in sight, and because of the present war trends, no lifesaver appears on the shores. What has influenced the public in our favor has been done by . . . disease and the un- . . . services to our patients . . . of illness. Politically and economically, we have been more or less helpless in changing the unpredictable drift of our profession. However, your Bureau of Public Relations is alert. The report of the Council presents the subject so concisely, your reference committee wishes to quote as follows:

"It is essential that public relations work be

already is that the x-ray part of it was stressed to such an extraordinary extent as the main thing necessary, and we wanted to see that everybody got his x-ray, indigent or not indigent.

I am perfectly willing to accept that modification of Part 7, since the idea has already gone forth that the x-ray is important. I think I approve of it.

SPEAKER BAUER: Is there any other discussion?

... There being no further discussion, the motion was put to a vote and was unanimously carried.

DR. DI NATALE: Part 8, which I previously read as it at present appears in the Council committee's report, is:

"All x-ray examinations at tuberculosis hospitals and clinics should be done without direct cost to the patients."

Your Committee felt that that should be amended to read as follows:

"All x-ray examinations at federal, state, or municipal hospitals should be done without direct cost to the patient."

I move the adoption of the reference committee's recommendation.

DR. BRITTAIN: I will second that.

SPEAKER BAUER: You have the recommendation of the reference committee that Part 8 will be amended to permit examination without direct cost to the patient only at federal, state, and municipal controlled institutions.

Is there any discussion on that?

DR. EDWARD P. FLOOD, *Bronx*: I would like to raise a question of verbiage. In New York City it is the health centers that do most of the control examinations. Dr. Di Natale mentions municipal hospitals, but in New York City they play little part in the control of contacts.

SPEAKER BAUER: Do you wish to suggest any change, Dr. Flood?

DR. FLOOD: I suggest a change in phraseology to include municipal health facilities as well as the municipal hospitals.

SPEAKER BAUER: Is that satisfactory to you? Is there any objection to that amendment being accepted?

DR. DI NATALE: No, the committee is willing to include that in its recommendation.

SPEAKER BAUER: There being no objection that will be made a part of the committee's report.

DR. DI NATALE: The committee's substitution, as thus amended, and accepted by the reference committee, will now read:

"All x-ray examinations at federal, state, or municipal hospitals, including municipal health facilities, should be done without direct cost to the patient."

DR. LYMAN C. LEWIS, *Allegany*: For a point of information, the state tuberculosis hospitals are at present holding clinics outside of the hospitals in which patients are admitted for x-ray examination. If this resolution says "municipal hospitals," is that intended to include those clinics run by the state?

DR. DI NATALE: Yes.

... There being no further discussion, the motion was put to a vote, and was unanimously carried.

DR. DI NATALE: Your committee heartily endorses the work of the Tuberculosis Conference Committee.

Under the heading of *The Deaf and Hard of Hearing*, your committee urges the endorsing and approval of the work done, and urges that it be continued.

I move the recommendation of the committee.

... The motion was seconded, and as there was no discussion, the motion was put to a vote, and was unanimously carried.

DR. DI NATALE: Now I move the adoption of the report, as amended, which amendment was accepted by the reference committee, as a whole.

... The motion was seconded, and as there was no discussion, the motion was put to a vote, and was unanimously carried.

SPEAKER BAUER: Thank you, Dr. Di Natale!

DR. GEORGE S. KOSMAK, *New York*: I believe the reference committee, either advertently or inadvertently, left out any comment on that section of this report devoted to venereal disease control.

SPEAKER BAUER: No, that was covered in the first section of the report. They recommended approval of what had been done and the continuation of activities along the same line.

DR. KOSMAK: Thank you!

Section 34

Report of Reference Committee on Report of the Council—Part IV: Publications and Medical Publicity

DR. ANDREW A. EGGSTON, *Westchester*: The appearance, composition, editorials, text, and in general the JOURNAL of the Society has been greatly improved, and is a distinct credit to the Medical Society of the State of New York. As is befitting the JOURNAL, it has published matters of practical interest to the general practitioner and important personal and economical news of its various constituted county societies. It would indeed be very pleasing, however, if some original scientific papers were published which tend to enhance its reputation as a medium for research work.

From a financial standpoint, it is interesting to note that there has been a decided improvement over 1941. Special attention is called to the installation of the new system of collections in 1941. As a result, on February 15, 1942, there remained unpaid on 1941 business the sum of \$140.70 of a total billing of \$71,485.47. There are many similar financial improvements, such as the decrease in authors' alteration costs, the raising of advertising rates, and a decrease in cash discounts. Also, there was a steady increase in gross income, from \$50,278.11 in 1939, to \$71,485.47 in 1941. There is a pleasant and noteworthy increase of advertising contracts from March 1, 1941, of \$69,867.00, to \$73,668.70 on February 16, 1942. This stability in medical advertising is very interesting and essential. It reflects credit upon the financial management of the JOURNAL. The report contains many other items of economy. Foresight has been exercised in the purchase of paper at favorable costs. Your reference committee is in accord with the idea of mailing the JOURNAL without wrappers. This would effect a saving of approximately \$1,500, and we trust the Publication Committee

will find this feasible. However, the committee does not recommend any change in the quality of the present cover of the JOURNAL. The pertinent point is that the average cost of the JOURNAL to each member was 88 cents for 1941, as compared to 91 cents for 1940. It is your committee's opinion that the JOURNAL is one of the best investments made by any member of the Society.

The Publication Committee of the *Directory* has considered the cost and prospective revenue, and we think they are in the best position to judge about the immediate future publication of the *Directory*. Therefore, the reference committee feels that the opinion of the Council in the postponement temporarily of the publication of the *Directory* is a wise one. That it should not be too long delayed is likewise obvious, and the decision for its publication during this emergency would be most expediently considered from year to year by leaving the date of publication to the discretion of the Council. The *Directory* is one of the greatest practical aids to the physician of any available publication. How could we get along without it! Again, financially it is an excellent \$1.02 investment. Further, this cost is a saving over the previous volume, and all commendation is due to the Publication Committee.

SPEAKER BAUER: Inasmuch as your last recommendation involves an action which is different from that the House ordered a year ago, I think we should stop at that portion of your report and act on it before proceeding to the next subdivision.

DR. EGGSTON: I move the adoption of that portion of the reference committee's report.

SPEAKER BAUER: This portion of the reference committee's report is before you for adoption. It includes a recommendation to postpone the publication of the *Directory*. The House originally directed that a *Directory* should come out this coming fall, and if the recommendation of the reference committee is adopted, it will necessarily delay such publication for a period of at least six months by action of the Council. If you approve of the recommendation of the reference committee, you will likewise approve of the action of the Council in delaying publication of the *Directory* because of the war situation. Is there any discussion?

DR. HARRY ARANOW, *Bronx*: Does that recommendation also encompass the thought that the Council, if it sees fit, can also delay the further publication of the *Directory*?

SPEAKER BAUER: Yes, it also recommends that the date of publication of the *Directory* be left to the Council in the immediate future.

Is there any further discussion on the motion?
... There were calls for the question, so the motion was put to a vote, and was carried. ...

DR. EGGSTON: In regard to medical publicity both on the radio and in the newspapers, there were many interesting subjects discussed and special attention is called to the article, "The Role of the Doctors in Defense," by Colonel Samuel J. Kopetzky, as well as other valuable contributions by this author. It is unfortunate that the radio broadcast has to be discontinued or curtailed because of the cost and the lack of a satisfactory sponsor, and we trust some means will

be forthcoming to resume this service to the public.

In relation to newspapers, the committee urges a further cooperation with all the newspapers of the state for releases of accurate and timely editorials and discussion of medical subjects of public interest. Too much stress cannot be placed upon the value of such discussions. In fact, there should be a committee of physicians and editorial writers in each county of the state to cooperate as an editorial board for the release of medical information to the public. This would avoid much misunderstanding and the publication of wrong information about physicians and medical subjects. The committee knows of no better way to reach the public than through a perfect understanding with the newspapers.

Postgraduate medical education has received excellent stimulation and cooperation from the State Society in the past year under able leadership. The establishment of refresher courses upon timely subjects should be further extended to encourage every county of the state. There are wonderful institutions of medical teaching throughout the state that should continue to be encouraged to offer refresher courses to the members of the Society.

The committee likewise thinks that the issuance of bulletins of the club talk series type is to be commended and continued, as they have been quite popular and extremely useful. It would be of interest to know the number of these sent to members and the cost.

The results of the Public Relations Committees of our county, state, and national societies have been at best intangible and from a practical purpose, a disappointment. However, these efforts may have delayed compulsory health insurance. But in the face of it all, the profession stands convicted as a trust, with the future of medicine most uncertain. This is in spite of the earnest and unselfish efforts of the many conscientious men serving on these committees. Perhaps the very modesty of our profession prevents the use of more militant tactics to protect our economy. The accomplishments of the medical profession to influence the trends of medicine pale when compared to the gain of labor groups, who in the opinion of high authority have not always bothered much about public relations.

Influencing people and making friends by talking and propaganda is one thing, but after this global war, it is apparent that more direct and positive methods will be needed to safeguard medical care.

It seems that our relations to the public are like an earless boat drifting down the Niagara River, soon to drop over the falls of Socialized Medicine. At present, there is no anchorage in sight, and because of the present war trends, no lifesaver appears on the shores. What has influenced the public in our favor has been done by the scientific prevention of disease and the unselfish and sympathetic services to our patients during distressing moments of illness. Politically and economically, we have been more or less helpless in changing the unpredictable drift of our profession. However, your Bureau of Public Relations is alert. The report of the Council presents the subject so concisely, your reference committee wishes to quote as follows:

"It is essential that public relations work be

continued throughout the war period. This is necessary to fulfill one of the purposes for which the Society exists, as stated in the Constitution: 'To enlighten and direct public opinion in regard to the problems of medicine and health for the best interests of the people of the State.' But continued public relations activity is also advisable for practical and utilitarian reasons. At the conclusion of the war, there will be a problem of unemployment the like of which this country has never seen. We shall find fixed upon the social order certain government policies of control over business, industry, and medicine, controls relinquished to the government willingly by the people because of the extremity of military needs, but which will not be ceded back to industry, business, medicine, and the people, without a battle for the preservation of individualism. This fight on behalf of medicine can only be waged in the forum of public opinion through a public relations bureau which has not been allowed to languish, but has continued to function, though on a restricted and rationed diet. We should keep up contacts with key persons, retaining the ear of the public and maintaining a mailing list, which will be invaluable in building public opinion at a future time when a public relations bureau may very well be the crucial factor in determining vital issues."

It is apparent to the committee that the efforts of this bureau be continued and should be augmented, as the judgment of the bureau deems wise.

Under the item "New Recommendations," this committee wishes to offer to the House of Delegates the serious consideration of a plan for the compilation of historical data, manuscripts, archives, biographic sketches, memoirs, scientific and practical contributions of this Society during this unprecedented war period.

Perhaps from time to time it would be opportune to publish some of the interesting historical events, ultimately to be followed by a final publication of a complete history of the contributions of the medical profession of the State of New York in this historical era.

I move the adoption of this portion of the report.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

DR. EGGSTON: Now the reference committee, consisting of Andrew A. Eggston, chairman, Albert A. Cinelli, James Greenough, Charles A. Anderson, and William A. MacVay, moves the adoption of this report as a whole.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

Section 35. (See 23)

Report of Reference Committee on New Business A—Waiving of Penalties for Failure to Attend Hospital Staff Meetings

DR. LEO F. SIMPSON, *Monroe*: On the resolution introduced by Dr. Harold B. Davidson, of the Medical Society of the County of New York, reading:

"WHEREAS, the duties of physicians working

in hospitals will increase greatly during the war; therefore be it

"Resolved, that the American Medical Association, the American College of Surgeons, and other national organizations, be petitioned to waive penalties to hospitals or doctors for failure to attend staff meetings in hospitals for the duration of the war and six months thereafter.

"On motion, this resolution was passed, and it was voted to refer the matter to the Coordinating Council and to instruct the Delegates of the Medical Society of the County of New York to introduce this resolution at the next meeting of the House of Delegates of the Medical Society of the State of New York."

your committee recommends that no action be taken on this resolution at this time.

... The motion was seconded.

SPEAKER BAUER: You have before you the committee's recommendation that no action be taken on this resolution at this time. Is there any discussion?

DR. HAROLD B. DAVIDSON, *New York*: The resolution was adopted by the county society because of the fact that with the tremendous amount of work that the doctors have to do during the war emergency, which will ever be increasing, such a requirement could very easily be let down. We were wondering what was the reason for the committee's recommendation that no action be taken on this resolution at this time.

DR. SIMPSON: The committee felt that this was rather a blanket petition, which did not seem necessary at this time. It was felt that these regulatory bodies would, no doubt, take into consideration all factors before taking any disciplinary measures during this war period.

SPEAKER BAUER: Is there other discussion? If not, all those in favor of the adoption of the reference committee's report, which carries with it no action on the resolution, will say "Aye"; those opposed, "No." The chair is in doubt. All those in favor of the adoption of the committee's report, which carries with it no action on the resolution, will please arise.

... All but about twenty-five arose.

SPEAKER BAUER: The motion is carried, and the report of the reference committee is adopted, which carries with it no action on the resolution.

Section 36. (See 20)

Report of Reference Committee on New Business A—Elimination of Required Certification of Checks in Payment of Tax Stamps for Opium Dispensing, Etc.

DR. SIMPSON: On the resolution introduced by Dr. W. P. Anderton, of the Medical Society of the County of New York, reading:

"WHEREAS the physicians and surgeons who dispense or prescribe opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required by federal law and regulations annually to purchase a special tax stamp for \$1.00; and

"WHEREAS, when payment of such dollar is made by check, it is required that such check be certified by the bank of payment; and

"WHEREAS, the Treasury Department of the

United States of America accepts checks for larger amounts without requiring certification; therefore be it

"Resolved, that the Medical Society of the State of New York protests against the requirement that checks for purchase of special tax stamps in connection with dispensing and prescribing opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required to be certified; and be it further

"Resolved, that the delegates from the Medical Society of the State of New York to the House of Delegates of the American Medical Association are hereby instructed to introduce a resolution at the 1942 session embodying this protest, and urging the American Medical Association to take emphatic and persistent steps toward the elimination of the requirement for certification of checks previously mentioned in this resolution; and be it further

"Resolved, that copies of this resolution be sent to important local and national dentist, veterinary, pharmacist, manufacturing chemist, and banker organizations, inasmuch as members of such organizations are also affected by the unnecessary labor of certification of small checks."

your committee recommends the approval of this resolution, and I so move.

... The motion was seconded

SPEAKER BAUER: You have before you the adoption of the committee's report recommending in substance approval of this resolution, which urges that steps be taken to make it unnecessary to certify checks for the purchase of narcotic stamp taxes, when checks for other taxes and government obligations are not required to be certified. Is there any discussion?

The question was called for, and the motion was put to a vote, and was unanimously adopted.

Report of Reference Committee on New Business A—Women Physicians and the Medical Reserve Corps of the Army and Navy

DR SIMPSON: On the resolution introduced by Dr Emily Dunning Barringer, of the Medical Society of the County of New York, concerning the woman physician in the Medical Reserve Corps of the United States Army and Navy, reading:

"WHEREAS, during the past winter women physicians have been denied commissions in the Medical Reserve Corps of the United States Army, because of their sex, and in spite of outstanding personal and professional qualifications, as for instance in the case of a skilled anesthetist attached to a base hospital which was ordered into active service, and in this case the colonel in charge and the chief surgeon highly endorsed and desired that this woman be a member of the staff of this base hospital, and

"WHEREAS, during this past winter two American women physicians have received commissions in the Royal Army Medical Corps of the British Army, one as a Major and

the other as a Lieutenant, and both have been assigned to military hospitals; and

"WHEREAS, the women physicians of the American Medical Association are a minority group, who, however, pay dues and take part in the activities of the Association, and turn help in their problems of and

"WHEREAS, there is no existing ruling that women are ineligible to the Medical Reserve Corps of the United States Army, while there is an existing ruling in the Navy, which could be removed by the proper authorities, and

"WHEREAS, at the last meeting of the House of Delegates of the Medical Society of the State of New York, the House went unanimously on record as approving that women physicians be admitted to the Medical Reserve Corps of the United States Army and Navy, and formally requested the American Medical Association to endorse their action, which was not accomplished, therefore be it

"Resolved, that the delegates from New York County be instructed to ask the House of Delegates to go on record again this year and ask the American Medical Association to aid one of its minority groups by endorsing and aiding women physicians in obtaining commissions in the Medical Reserve Corps of the United States Army and Navy,"

the Committee recommends the approval of this resolution, and I so move.

... The motion was seconded

SPEAKER BAUER: You have before you the report of the reference committee recommending approval of the resolution, which in effect reiterates the stand taken by the House last year urging that women physicians be made eligible for commissions in the Medical Corps of the Army and Navy. Is there any discussion on the report? If not, all in favor of its adoption say "Aye"; contrary, "No" The chair is in doubt. Will all those in favor of its adoption please rise? Now those opposed will rise

... All the delegates were in favor of the adoption of the reference committee's report except five.

SPEAKER BAUER: The motion is carried, and the report of the reference committee and the resolution are adopted

Section 38 (See 28, 69)

Report of Reference Committee on New Business A—Suggested New Subcommittee on Tuberculosis Control

DR SIMPSON: This resolution reads

"WHEREAS, the problem of tuberculosis control has never been attacked as intensively or as effectively as that of syphilis, and

"WHEREAS, the Commissioner of Health of the State of New York has recently instituted a campaign to eradicate tuberculosis from this state by the year 1960 and needs the combined efforts of the medical profession to insure the success of this project; and

"WHEREAS, tuberculosis is a highly contagious and yet preventable disease, and many possible sources from which it may be spread to healthy contacts are still existent, and

"WHEREAS, to effectively investigate these sources, such measures as routine tuberculin

continued throughout the war period. This is necessary to fulfill one of the purposes for which the Society exists, as stated in the Constitution: 'To enlighten and direct public opinion in regard to the problems of medicine and health for the best interests of the people of the State.' But continued public relations activity is also advisable for practical and utilitarian reasons. At the conclusion of the war, there will be a problem of unemployment the like of which this country has never seen. We shall find fixed upon the social order certain government policies of control over business, industry, and medicine, controls relinquished to the government willingly by the people because of the extremity of military needs, but which will not be ceded back to industry, business, medicine, and the people, without a battle for the preservation of individualism. This fight on behalf of medicine can only be waged in the forum of public opinion through a public relations bureau which has not been allowed to languish, but has continued to function, though on a restricted and rationed diet. We should keep up contacts with key persons, retaining the ear of the public and maintaining a mailing list, which will be invaluable in building public opinion at a future time when a public relations bureau may very well be the crucial factor in determining vital issues."

It is apparent to the committee that the efforts of this bureau be continued and should be augmented, as the judgment of the bureau deems wise.

Under the item "New Recommendations," this committee wishes to offer to the House of Delegates the serious consideration of a plan for the compilation of historical data, manuscripts, archives, biographic sketches, memoirs, scientific and practical contributions of this Society during this unprecedented war period.

Perhaps from time to time it would be opportune to publish some of the interesting historical events, ultimately to be followed by a final publication of a complete history of the contributions of the medical profession of the State of New York in this historical era.

I move the adoption of this portion of the report.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

DR. EGGSTON: Now the reference committee, consisting of Andrew A. Eggston, chairman, Albert A. Cinelli, James Greenough, Charles A. Anderson, and William A. MacVay, moves the adoption of this report as a whole.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

Section 35. (See 23)

Report of Reference Committee on New Business A—Waiving of Penalties for Failure to Attend Hospital Staff Meetings

DR. LEO F. SIMPSON, *Monroe*: On the resolution introduced by Dr. Harold B. Davidson, of the Medical Society of the County of New York, reading:

"WHEREAS, the duties of physicians working

in hospitals will increase greatly during the war; therefore be it

"Resolved, that the American Medical Association, the American College of Surgeons, and other national organizations, be petitioned to waive penalties to hospitals or doctors for failure to attend staff meetings in hospitals for the duration of the war and six months thereafter.

"On motion, this resolution was passed, and it was voted to refer the matter to the Coordinating Council and to instruct the Delegates of the Medical Society of the County of New York to introduce this resolution at the next meeting of the House of Delegates of the Medical Society of the State of New York."

your committee recommends that no action be taken on this resolution at this time.

... The motion was seconded.

SPEAKER BAUER: You have before you the committee's recommendation that no action be taken on this resolution at this time. Is there any discussion?

DR. HAROLD B. DAVIDSON, *New York*: The resolution was adopted by the county society because of the fact that with the tremendous amount of work that the doctors have to do during the war emergency, which will ever be increasing, such a requirement could very easily be let down. We were wondering what was the reason for the committee's recommendation that no action be taken on this resolution at this time.

DR. SIMPSON: The committee felt that this was rather a blanket petition, which did not seem necessary at this time. It was felt that these regulatory bodies would, no doubt, take into consideration all factors before taking any disciplinary measures during this war period.

SPEAKER BAUER: Is there other discussion? If not, all those in favor of the adoption of the reference committee's report, which carries with it no action on the resolution, will say "Aye"; those opposed, "No." The chair is in doubt. All those in favor of the adoption of the committee's report, which carries with it no action on the resolution, will please arise.

... All but about twenty-five arose.

SPEAKER BAUER: The motion is carried, and the report of the reference committee is adopted, which carries with it no action on the resolution.

Section 36. (See 20)

Report of Reference Committee on New Business A—Elimination of Required Certification of Checks in Payment of Tax Stamps for Opium Dispensing, Etc.

DR. SIMPSON: On the resolution introduced by Dr. W. P. Anderton, of the Medical Society of the County of New York, reading:

"WHEREAS the physicians and surgeons who dispense or prescribe opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required by federal law and regulations annually to purchase a special tax stamp for \$1.00; and

"WHEREAS, when payment of such dollar is made by check, it is required that such check be certified by the bank of payment; and

"WHEREAS, the Treasury Department of the

United States of America accepts checks for larger amounts without requiring certification; therefore be it

"Resolved, that the Medical Society of the State of New York protests against the requirement that checks for purchase of special tax stamps in connection with dispensing and prescribing opium or coca leaves or any compound, manufacture, salt, derivative, or preparation thereof, are required to be certified; and be it further

"Resolved, that the delegates from the Medical Society of the State of New York to the House of Delegates of the American Medical Association are hereby instructed to introduce a resolution at the 1942 session embodying this protest, and urging the American Medical Association to take emphatic and persistent steps toward the elimination of the requirement for certification of checks previously mentioned in this resolution; and be it further

"Resolved, that copies of this resolution be sent to important local and national dentist, veterinary, pharmacist, manufacturing chemist, and banker organizations, inasmuch as members of such organizations are also affected by the unnecessary labor of certification of small checks,"

your committee recommends the approval of this resolution, and I so move.

... The motion was seconded.

SPEAKER BAUER: You have before you the adoption of the committee's report recommending in substance approval of this resolution, which urges that steps be taken to make it unnecessary to certify checks for the purchase of narcotic stamp taxes, when checks for other taxes and government obligations are not required to be certified. Is there any discussion?

... The question was called for, and the motion was put to a vote, and was unanimously adopted.

Section 37. (See 26)

Report of Reference Committee on New Business A—Women Physicians and the Medical Reserve Corps of the Army and Navy

DR. SIMPSON: On the resolution introduced by Dr. Emily Dunning Barringer, of the Medical Society of the County of New York, concerning the woman physician in the Medical Reserve Corps of the United States Army and Navy, reading:

"WHEREAS, during the past winter women physicians have been denied commissions in the Medical Reserve Corps of the United States Army, because of their sex, and in spite of outstanding personal and professional qualifications, as for instance in the case of a skilled anesthetist attached to a base hospital which was ordered into active service, and in this case the colonel in charge and the chief surgeon highly endorsed and desired that this woman be a member of the staff of this base hospital; and

"WHEREAS, during this past winter two American women physicians have received commissions in the Royal Army Medical Corps of the British Army, one as a Major and

the other as a Lieutenant, and both have been assigned to military hospitals; and

"WHEREAS, the women physicians of the American Medical Association are a minority group, who, however, pay dues and take part in the activities of the Association, and turn to the Association for help in their problems of medical opportunities; and

"WHEREAS, there is no existing ruling that women are ineligible to the Medical Reserve Corps of the United States Army, while there is an existing ruling in the Navy, which could be removed by the proper authorities; and

"WHEREAS, at the last meeting of the House of Delegates of the Medical Society of the State of New York, the House went unanimously on record as approving that women physicians be admitted to the Medical Reserve Corps of the United States Army and Navy, and formally requested the American Medical Association to endorse their action, which was not accomplished; therefore be it

"Resolved, that the delegates from New York County be instructed to ask the House of Delegates to go on record again this year and ask the American Medical Association to aid one of its minority groups by endorsing and aiding women physicians in obtaining commissions in the Medical Reserve Corps of the United States Army and Navy,"

the Committee recommends the approval of this resolution, and I so move.

... The motion was seconded.

SPEAKER BAUER: You have before you the report of the reference committee recommending approval of the resolution, which in effect reiterates the stand taken by the House last year urging that women physicians be made eligible for commissions in the Medical Corps of the Army and Navy. Is there any discussion on the report? If not, all in favor of its adoption say "Aye"; contrary, "No." The chair is in doubt. Will all those in favor of its adoption please rise? Now those opposed will rise.

... All the delegates were in favor of the adoption of the reference committee's report except five.

SPEAKER BAUER: The motion is carried, and the report of the reference committee and the resolution are adopted.

Section 38. (See 28, 69)

Report of Reference Committee on New Business A—Suggested New Subcommittee on Tuberculosis Control

DR. SIMPSON: This resolution reads:

"WHEREAS, the problem of tuberculosis control has never been attacked as intensively or as effectively as that of syphilis; and

"WHEREAS, the Commissioner of Health of the State of New York has recently instituted a campaign to eradicate tuberculosis from this state by the year 1960 and needs the combined efforts of the medical profession to insure the success of this project; and

"WHEREAS, tuberculosis is a highly contagious and yet preventable disease, and many possible sources from which it may be spread to healthy contacts are still existent; and

"WHEREAS, to effectively investigate these sources, such measures as routine tuberculin

testing of older children, mass x-ray examination of those living in sections that have a high incidence of tuberculosis, routine (yearly) examination of food handlers, domestics, and school teachers, and more adequate care and supervision of the tuberculous and ex-tuberculous patient will be necessary; therefore be it

"Resolved, that an intensive educational program and campaign be instituted throughout the state under the auspices of the Medical Society of the State of New York to acquaint the general public and medical profession with the effective ways and means in the prevention and control of tuberculosis; and be it further

"Resolved, that a subcommittee on tuberculosis control to serve under the Council Committee of Public Health and Education or a separate committee be appointed; and be it further

"Resolved, that this committee should cooperate with the Commissioner of Health and the various agencies interested in the problem of tuberculosis to institute such measures as will make this program effective, and that an offensive rather than a defensive campaign against the disease should be put into operation."

Your committee recommends the disapproval of this resolution on the ground that this function is now adequately cared for by the Council Subcommittee on Public Health and Education.

I move the adoption of the committee's recommendation.

... The motion was seconded. ...

SPEAKER BAUER: You have before you the report of the reference committee, which recommends disapproval of the resolution on the ground that the matter is now being adequately cared for by the present Council Committee on Medical Education. Is there any discussion?

DR. LEO F. SCHIFF, *Clinton*: It seems hard for me to believe that the committee actually disapproves of the whole resolution. The clause apparently to which they take exception is the one directing the appointment of a special subcommittee. I do not believe that the majority of the members of this House of Delegates want the State Society to put itself in the position of being misunderstood. I think we can approve of this resolution if that final clause is left out, or the final two clauses are deleted.

I will move you as an amendment to this motion that this resolution be approved, with the omission of this particular clause:

"Resolved, that a subcommittee on tuberculosis control to serve under the Council Committee on Public Health and Education or a separate committee be appointed,"

and the substitution in the last paragraph which begins:

"Resolved, that this committee should cooperate," and so on,
of the following:

"Resolved, that this Committee of Public Health should continue to cooperate," etc.,

thereby giving thought and effect to the motion which I personally believe is in accord with the wishes of this House; in other words, deleting the clause that directs the appointment of a subcommittee and stating that, instead of our

cooperating, the thought that we have been cooperating and we shall continue to cooperate with the Commissioner of Health and the various agencies interested in the problem of tuberculosis.

SPEAKER BAUER: Your motion is not properly an amendment to the original motion, but is a substitute motion. The committee recommended rejection of the resolution. If you wish to move as a substitute motion that the resolution be adopted with the deletion of the clause providing for the separate subcommittee and directing that the Council committee continue to cooperate, I will accept that as a substitute.

DR. SCHIFF: Yes, that is my thought, Mr. Speaker.

SPEAKER BAUER: Does anybody second the substitute motion?

DR. WILLIAM H. ROSS, *Past-President*: I will second that substitute motion.

SPEAKER BAUER: The question before the House is on the adoption of the substitute motion in place of the motion of the committee chairman. Is there any discussion on the substitution of Dr. Schiff's motion for Dr. Simpson's?

DR. W. GUERNSEY FREY, Jr., *Queens*: I don't believe it is very clear to all the members of the House just what Dr. Schiff intends by his substitute motion. Might not Dr. Schiff accept a suggestion that this be referred back to the reference committee for further study and later report?

DR. SCHIFF: Yes, that would be agreeable to me.

DR. ROSS: I have no objection to its being recommitted to the reference committee.

SPEAKER BAUER: Do you so move?

DR. FREY: Yes.

DR. SCHIFF: I will second that.

SPEAKER BAUER: Dr. Frey moves to recommit the resolution to the reference committee for further study and report. Is there any discussion on the motion to recommit?

SECRETARY IRVING: I think an explanation of how the Medical Society of the State of New York became involved in the present Conference Committee on Tuberculosis is in order.

That was started up by an agreement among the Commissioner of Health, the Commissioner of Mental Hygiene, the Commissioner of Welfare, the State Charities Aid, and the Metropolitan Life Insurance Company. At the end of 1940, I received personally a request from the Commissioner of Health to serve on that conference committee as a representative of the Medical Society. Very shortly thereafter I requested, with the approval of the Council, that the committee consider the addition of Dr. Mitchell, as chairman of our Council Committee on Public Health, and Dr. Hambrook, as chairman of our Council Committee on Public Relations and Economics. That was agreed to instantly, and you are now represented by these three people, Mitchell, Hambrook, and myself, on that Committee. We are all deeply interested in it, and it has been a forward-looking effort, and it is continuing so ... There being no further discussion, the motion to recommit was put to a vote, and was adopted. ...

SPEAKER BAUER: That resolution is recommitted, and after further study by the reference committee, it will be resubmitted to the House.

DR. SIMPSON: Is it recommitted with that modification, as suggested by Dr. Schiff, incorporated in it?

SPEAKER BAUER: No, that is up to the committee to decide. No vote was taken on the substitute motion.

Section 39. (See 15)

Report of Reference Committee on New Business A—Medical Expense Indemnity Insurance

DR. SIMPSON: On the resolution introduced by Dr. Abraham Koplowitz, of Kings County, reading:

"WHEREAS, the Insurance Law, in Article IX-C, provides for voluntary nonprofit cash indemnity insurance, and (through representations made on behalf of the Medical Society of the State of New York) the law now provides that no corporation shall be licensed to furnish both hospital and medical insurance; and

"WHEREAS, the Hampton-Wright bill introduced in the present session of the legislature would permit hospital service insurance plans to include indemnity for physicians' and surgeons' fees in their contracts; and

"WHEREAS, any medical indemnity furnished through a hospital insurance contract would make the service of doctors incidental to the institutional services, with control of all details of such indemnity and service in the hands of lay dominated boards of management; and

"WHEREAS, the Hampton-Wright bill has been put off to the next session of the legislature with due notice that it will be pressed for favorable consideration if by that time medical insurance under administrative control of the medical profession has not developed a reasonably satisfactory participation on the part of both the profession and the public; and

"WHEREAS, the relatively small enrollment of subscribers and the incomplete participation of the medical profession during the past year have been due in part to the lack of outright full support of such enterprises by the organized medical societies; and

"WHEREAS, the Hampton-Wright bill, if enacted, will give the hospitals a legal entry into the practice of medicine, which in turn will constitute a long step toward lay control of medical practice and ultimately to a system of government medical service in the hands of a bureaucracy; and

"WHEREAS, the Council of the Medical Society of the State of New York has '... recognized with satisfaction the creation of three organizations for nonprofit medical expense indemnity insurance. In the opinion of the Council, the three have followed the tentative basis and suggestions for medical expense indemnity insurance that were set up by the House of Delegates on April 24, 1939'; therefore be it

"Resolved, that the Medical Society of the State of New York now officially approve, sponsor, and support in every manner possible the three corporations which have conformed to the principles prescribed by Organized Medicine for the protection of the interests of both the public and the profession in the organ-

ization and operation of medical insurance, namely, the Western New York Medical Plan, Inc., of Buffalo; the Medical and Surgical Care, Inc., of Utica; and the Medical Expense Fund of New York, Inc., of Brooklyn; and be it further

"Resolved, that notice of this action of the House of Delegates be given to the county Medical Societies (within the territory of the organizations thus endorsed), and that each one be urged to cooperate in every practical manner toward the accomplishment of a successful operation of voluntary nonprofit cash indemnity insurance by these organizations, within their respective fields of influence and interest, in order that a system of medical insurance under administrative control of the medical profession shall be developed and maintained."

your committee recommends the adoption of this resolution, with the amendment that the final paragraph should read as follows:

"Resolved, that notice of this action of the House of Delegates be given to all County Medical Societies of the State of New York, and that each one be urged to cooperate in every practical manner toward the accomplishment of the successful operation of voluntary nonprofit cash indemnity insurance by these organizations, in order that a system of medical insurance under administrative control of the medical profession shall be developed and maintained."

Your reference committee further recommends that a copy of this resolution be sent to the Commissioner of Insurance of the State of New York.

I so move.

DR. DEFORD W. BUCKMASTER, *Chautauqua*: I second that motion.

SPEAKER BAUER: You have before you the report of the reference committee on New Business A, which recommends the adoption of the resolution as submitted, plus an amendment. Is there any discussion on the report of the reference committee?

DR. HARRY ARANOW, *Bronx*: It seems to me that this urging of recognition by the State Society of three certain organizations is contrary to the declared policy of the State Society. One of these special groups to my knowledge has gone around to the different county societies and spoken about its plan, yet some of the counties have disapproved of it, or at least they have failed to approve it.

The main requirement of the State Society is that such an organization must comply with a number of rules that have been approved by the State Society. Therefore, I do not feel now that the State Society ought to go on record as sponsoring any one organization. Let every organization stand on its own legs. Our sponsoring any organization will put us in the position where we will be behind it without actually controlling it, and we will be left holding the bag if it should decide later to change any of its principles.

I feel personally that this should be left entirely to the individual county societies involved, without the State Society's endorsement of any one plan.

For the benefit of the men upstate, I may say

that I have particular reference to the Kings County Plan. While I am not opposed to Kings County, I am opposed to any group making the State Society stand behind their plan for no reason at all, as far as I can see. (Applause)

DR. JAMES F. ROONEY, *Past-President*: I think this resolution is a dangerous one. However, all of us realize, because we are realists, that we are approaching a period of collectivism, which is going to become more and more marked as time goes on; but I feel just as my old friend, Aranow, has just told you, that it is a dangerous principle for us to approve of any particular groups or any particular companies. To approve of the matter of medical indemnity insurance in principle, yes, but here we have essentially only three corporations, excellent in intent, relatively efficient in their localities in purpose, although on the other hand they have not received as yet the approval of the whole Society, especially in relation to its county components. Unfortunately, we are slow, as we always have been slow, and we are going to have to accelerate our speed because Congress has passed, within the last two weeks, one of the entering wedges that we have been dealing with for the last thirty-odd years that will provide hospitalization and medical care for all persons employed in industry in the United States. The bill, so far as I know, has not yet been signed, but I learn it will probably be signed.

I hope that the House will not approve by name these three corporations, but that it will approve of the principle of medical indemnity insurance and do something to further the extension of this service to all the people of the state.

To that end, Mr. Speaker, I move a substitute motion that will delete the names of any of the corporations mentioned in the resolution as approved by the reference committee, and the inclusion of a provision to the effect that the Society approves the principle of medical indemnity insurance and, if it be the wish of the House, that a committee be appointed or that the matter be referred to a proper committee for the intensification of the plan for the institution and extension of this service throughout the state. My substitute motion, then, will be that we approve the report of the committee, substituting for the names of the three corporations concerned the principle of medical indemnity insurance.

SPEAKER BAUER: You have heard the substitute motion made by Dr. Rooney, that instead of the inclusion of the three organizations concerned there be substituted approval of the principle of medical indemnity insurance, otherwise the committee's report to stand approved as read. Is that substitute motion seconded?

DR. GEORGE W. KOSMAK, *New York*: Yes, I will second it.

DR. HERBERT H. BAUCKUS, *Erie*. I speak as the chairman of the Subcommittee on Medical Indemnity Insurance Plans now in vogue in the State of New York.

The Medical Society of the State of New York, in 1939, and the American Medical Association approved the principles under which these mentioned companies are now operating. Each year since, we have gone so far as to approve the principles, and that is as far as we have gone. I will say that these companies are operating under

the principles which we enunciated and which were brought out each year here by the House of Delegates, and I would take it that if they were not operating in that manner, then we would be bound to disapprove of them; therefore, we are really approving them. They follow our desires.

The statement has been made, and is being made more and more, that even though in various localities efforts have been made to provide medical indemnity insurance, the medical profession individually, and especially as a group, have done very little to support those plans. That, after all, is the truth, and, as our report bears out this year, these companies, who have volunteered and gone into this work that we really set up for them, have not had our support as much as they should have had it, and as much as they needed it. We might as well say right here and now, "Let us forget about any company doing anything in New York State unless the Medical Society gives it a more definite approval than it has in the past."

The law plainly states that the largest number of counties that may take part in a single plan is eighteen. Some of them have two or three counties. One has six. The Brooklyn Plan has seventeen. Therefore, under the law it is impossible to approve of a state-wide plan. We might have some master plan developed and brought out that we would urge counties to follow, but we cannot have an entire state plan.

I think it would be very unfortunate at this stage of affairs, especially with the hospital insurance under social security now looming up, to have the Medical Society of the State of New York take any action which would seem to push back the efforts of these people who have worked so well for us. We owe a great deal to each of these three groups, and I would like to see us do something for them. I think this is the time to do it. (Applause)

DR. ABRAHAM KOPLOWITZ, *Kings*. Mr. Speaker and Gentlemen, some twenty-one or twenty-two years ago I was in Albany with Dr. Rooney fighting against compulsory health insurance. It is time that we stopped fiddling while Rome is burning. We are threatened with compulsory insurance of various types, state and national. Dr. Rooney just informed you that the national government is planning something that will be nation-wide. Here in New York State, particularly, the medical profession has taken a stand against compulsory health insurance, and has said, "Let us try." It was not said officially by the State Society, but sufficiently so to have it understood by the public that the medical profession is going to try something.

The result was that a few organizations, three that I know of, were started by medical men, and another group by lay people using as window dressing medical names. The companies that are mentioned in this particular resolution, so far as we know, are the only ones that have submitted plans, shown their scope, their organization, and met every requirement that this House of Delegates has placed upon such plans. The idea of our talking about medical expense indemnity and the moment something concrete is mentioned saying, "Don't touch it," and being afraid, is absurd. You might as well once and for all make up your mind to stop fooling yourselves. Either

let the government and the public do as they please about this or do something yourselves. You cannot stop every little progress that is made.

We are naming these particular companies because they represent certain counties. There may be others formed to take care of the rest of the counties. If they are conforming, and will conform, to all the tenets that the State Medical Society and the American Medical Association have specified for such organizations, we will approve them. The least you can do is to encourage those that are making an effort. If you don't want to do that, stop talking about medical expense indemnity and stop fighting compulsory health insurance. Take whatever is coming to you. I cannot see the idea of delaying it and being afraid of a name. These companies were organized by members of your own body, members of the State Medical Society. They certainly are not looking for profit. They are trying to forestall something. The least we can do is to help them. (Applause)

SECRETARY IRVING: I merely wish to give a little information that I think will be to your interest. Last October I was invited to go to Buffalo to speak before a meeting of the social welfare people. Following me was Michael Davis. I spoke about these three companies, and the fact that they were going along slowly but proceeding. I rather stressed the value of slow development, comparing it with the soundness of the practice of a doctor that develops slowly when he first goes into practice, yet is the soundest type of practice to have. I went along that way, and Michael Davis came along behind. Michael Davis, whom you all know, said he was greatly interested to know about these companies and their slow development, but that there were others who believed in a more nation-wide type of insurance. He did not specify who they were, but that was the inference, that it was to be federal, and those others were watching with great interest the development, and that if these companies did not succeed then another thing could be done. That was the gist of what he had to say, and I think that the time has come when anything we can do, and properly do, to foster the development, the more rapid development, of these three perfectly good companies, it will be well to do. (Applause)

DR. HOMER J. KNICKERBOCKER, *Ontario*: Mr. Speaker and Delegates, these three companies are the children of the brain of this organization. Are we going to disown them at this time by deleting their names from this resolution? It does not seem reasonable to me, nor do I think it is fair to do that. It seems to me that everyone who knows anything about the progress of these companies knows their names. You are not concealing anything; you are just pussyfooting around; you are just backing down. I see no reason why their names should not be retained in this report.

We, in the Finger Lakes Region in the western part of the state, have been deprived of the privileges of medical indemnity insurance because of the fact that no organization of that character has developed in the territory. We would be anxious and willing to join either Utica or Buffalo. (Applause)

DR. THOMAS A. MCGOLDRICK, *Kings*: To cor-

rect very briefly just one statement which might have connotations not intended: It has been stated that this is a sponsoring of one plan, which means that no other plan would be approved, or sponsored, or encouraged by the State Society.

There is nothing in this resolution which prohibits the development of the Three-Cent-A-Day Hospital Plan. There is nothing in the resolution to prevent any doctor in this body from presenting today or tomorrow another plan and having it submitted to a committee and having it receive the approval which it would deserve. There is nothing to give any company a monopoly, as it was implied, of the entire care of the sick from the financial standpoint. It is one measure that has met all the requirements laid down for it by the State Society, has been in practice for a short while, and that has not received the encouragement that it deserves. We have stood for the principles under which these organizations were started, and now when the practical application arises and endorsement is requested from this body which has laid out the principles, then, through fear, or conservatism, or some other feeling of our minds, we backwater and do nothing.

That has been the criticism of the State Departments, it has been the criticism of the Social Security Department, and all those others that watch us, and who would tear things to pieces, while we stand by and do nothing about it. We have been told from Washington, we have been told from Albany, and we have been told in the immediate past by the Superintendent of Insurance, "If you are not able to do anything on this question, then we will put through another plan within a year."

In this time of confusion, when it would be so easy to stampede people into an acceptance of laws, especially on social security, it would be a very dangerous matter for the medical profession to continue a policy of doing nothing.

I hope that the report of the reference committee will be approved.

DR. J. RICHARD KEVIN, *Past-President*: I should like to discuss another phase of the question. It has been mentioned here the fear of putting down the names of the men who have had the temerity and the courage to start something that we all conceive to be sound in principle. All we want to do now is to show that that principle can be and will be carried out. The part of it I desire to mention is that another state body has endorsed this organization. It is the State Board of Social Welfare, of which I have been a member for twenty-nine years—no salary though, gentlemen, no salary. (Laughter) When it came before us for certification, we studied the question and said, "Here is a chance. Here is an opportunity." For heaven's sake, don't let this body go home and say they were afraid of it.

DR. CARLTON E. WERTZ, *Erie*: Mr. Speaker and Members of the House of Delegates, I happen to be one of the representatives of the Western New York Medical Plan. We have been in operation for a little over two years. We are going slowly, as all these things do; but I think we are going—and not only we but all through the state—too slowly to keep up with things that are coming in from the outside.

One of the greatest difficulties we have is to get

the wholehearted support of the doctors. It is not only the public you have to sell, but you have got to sell the doctors these things first; and that is the biggest problem we have. It does not do any good for any of these organizations to try to go on if they do not have the support of the entire profession. We find that true, and it is true here in this end of the state as well as in our end of the state. This thing is getting to be serious right now.

You are all familiar with the Hampton Bill, which was introduced into our Legislature this year, and laid on the table to hold over for next year, and which provides that the hospital insurance will be able to give medical and surgical services, if we don't take care of this ourselves. I have here a copy of a letter from Louis H. Pink, Superintendent of Insurance of the State of New York, which he wrote to Dr. Benjamin M. Bernstein, secretary of the Medical Society of the County of Kings, under date of March 16, 1942, reading:

"Dear Dr. Bernstein:

"I do not think the proposed amendment permitting hospital associations to give surgical benefits will get anywhere this year. However, I do think it will become a law eventually unless the medical indemnity corporations really amount to something. So far they have not made good.

"We shall take no active steps to get the bill through this year but expect to do it next year unless there is a change in the situation.

"With best wishes,

"Sincerely yours,

(Signed) LOUIS H. PINK,
Superintendent of Insurance."

That is a serious thing, and I think it is about time we should do something definite and take some active stand in this matter.

DR. CHAS. GORDON HEYD, *Past-President*: I want you to go back in your memory with me to a meeting of the House of Delegates of the American Medical Association when the late Senator J. Hamilton Lewis, of Illinois, at his own invitation addressed the A.M.A.

In substance, he said that the day of private practice was finished, and hereafter the medical profession of the United States was in a civilian army, to be paid by it, and any individual could demand and receive any hospital services in their neighborhood or any professional services that he desired, and the doctor would have no voice in the matter as he would be in the army of the United States, taking care of the health and illnesses of the people of this country.

Considerable water has gone over the dam since then, during which this body, of which you are the representatives, set forth limitations and certain guiding principles for companies to follow that were seeking to write cash indemnity insurance. Up to date, three companies have complied with every regulation that you have made, and they are now coming here and saying in effect, "Have we acquitted ourselves of your injunctions?" All you want to do is to pat them on the back, and send them out again without recognition.

Let me tell you there have been plenty of heartaches on the part of some of the men who devised these plans. In this room are men who

devised one of these companies beginning four or five years ago, and who went down into their own personal fortunes to put up the money to run this thing. None of these three mentioned companies can succeed if any member of the Medical Society of the State of New York says, "My State Society has not recognized you."

If you do not adopt the report of the reference committee, you will pass over the control of medical practice to lay groups who, working through the front door of the hospital, will dominate medical practice and hospital practice. Abuses will arise in that system, as in England with the Friendly Societies and the Labor Medical Societies, and the government overnight will take the skeletonized, impoverished form of these organizations and you will have Federal Medicine.

The time has passed, gentlemen, when we can sit here and say, "We approve in principle." Aren't there enough of you here to go forward and fight for your own preservation? If there are, you will adopt the resolution and the report of the reference committee. (Applause)

DR. JAMES F. ROONEY, *Past-President*: I just want to withdraw my motion, Mr. Speaker. (Applause) I had not intended doing what I did. The intent was to sort of wake this House up. It seemed to me when I came in that it was indulging in insomnia in reverse, and I had the feeling in a matter so important as this that this resolution was entitled to more discussion than it was about to receive. I felt perfectly certain that touching upon anything in relation to compulsory health insurance, with which of course, in the last thirty years I am totally and completely unfamiliar and have done nothing about, we might at least galvanize this House into some sort of activity. I am amazed, surprised, and delighted to see the flame spark from every eye and the words of passion and emotion from every mouth. I withdraw my motion. (Applause)

DR. GEORGE W. KOSMAK: I withdraw my second.

DR. HARRY ARANOW: The reason I made the suggestion was that I hated to see the State Society sponsor this thing. You can encourage it, but you should not sponsor it. Why do I say that? Because I have been told by men who know insurance from the beginning to the end that this thing is impractical and is not going to succeed. That is my personal opinion, and I would hate to see the State Society go behind it and then have the thing fail. So long as we encourage it, and are not as an organization sponsoring it, it will not place us in an embarrassing position. I do not think it is going to succeed; in fact, I have been told by men high up in insurance that this thing is bound to fail, and I am sure there are men on the platform today who have said the same thing.

DR. JAMES F. ROONEY: There was one statement, however, that was made in the discussion which is incorrect. It was to the effect that the Hampton-Wright Bill would lie over until the next legislative session, and then be acted on. That is a misunderstanding or a misstatement. No bill can lie over from one legislative session to the next in the State of New York. When the Legislature adjourns sine die, everything is dead, and nothing can lie over until the next session.

SPEAKER BAUER: I take it there is no objection to the withdrawing of Dr. Rooney's motion. Hearing none, we can proceed to discuss the motion of the reference committee chairman which calls for the approval of the resolution as submitted, plus the amendment added by the reference committee. Is there any discussion on that motion?

. . . . The question was called for, and the motion was put to a vote, and was carried. . . . (Applause)

Section 40. (See 25)

Report of Reference Committee on New Business C—Connecticut State Medical Society, 150th Anniversary

DR. HARRY C. GUESS, Erie: On the resolution presented by Dr. Benjamin M. Bernstein, of the Medical Society of the County of Kings, reading:

"WHEREAS, the Medical Society of the State of Connecticut is celebrating the 150th anniversary of its founding at Middletown, Connecticut, on June 3 and 4, 1942; and

"WHEREAS, friendly relations between neighboring states particularly should always be maintained; be it

"Resolved, therefore, that two delegates of the Medical Society of the State of New York be sent as representatives to the Convention of the Medical Society of the State of Connecticut on the above-mentioned dates in order to join with them in the celebration of their 150th Anniversary,"

the committee recommends approval. I so move.

. . . . The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. . . .

Section 41. (See 17, 42)

Report of Reference Committee on New Business C—Opposition to Attempts to Lower Standing of Medical Practice or Conduct

DR. GUESS: This is on the resolution presented by Dr. Bedell, past-president of this organization, reading:

"WHEREAS, it has come to our attention that resolutions may be introduced in the House of Delegates of the American Medical Association which we believe will lower the ethical standing of the members of the profession; and

"WHEREAS, we are convinced that any attempt to so alter the professional standing of our members would be detrimental to the public health; be it therefore

"Resolved, that the House of Delegates of the Medical Society of the State of New York, in annual session assembled, hereby registers its protest of any such contemplated changes; and further be it

"Resolved, that the delegates from the Medical Society of the State of New York to the American Medical Association be instructed to oppose any and every attempt to lower the standing of medical practice or conduct."

The committee recommends approval of this resolution, and I so move.

. . . . The motion was seconded. . . .

SPEAKER BAUER: You have before you the report of the reference committee, which recommends adoption of this resolution, which is in effect a protest against the lowering of the standards of ethics of the American Medical Association.

DR. ABRAHAM KOPLOWITZ, Kings: Just what does this refer to?

SPEAKER BAUER: Can you answer it, Dr. Guess?

DR. GUESS: We have another resolution dealing with the same subject from Dr. Irl H. Blaisdell, secretary of the Syracuse Eye, Ear, Nose, and Throat Club, which explains this pretty fully, and which we will act upon later.

Dr. Bedell went before this committee and explained the situation. Apparently, if you will notice this resolution, it is really a blanket coverage for anything that is ethical and against anything that is nonethical. It makes no specific mention of any one particular offense which might be brought before the American Medical Association or against our profession; so being of that type we felt that we should pass this resolution first because of its blanket coverage.

SPEAKER BAUER: Does that answer your question?

DR. KOPLOWITZ: Frankly, no. I don't see how we can possibly question that the American Medical Association knows its ethics, too.

PRESIDENT KOFETZKY: Gentlemen, I have been a delegate from the Medical Society of the State of New York to the American Medical Association for a number of years. In our enthusiasm, or, as Dr. Rooney says, in our somnambulism, we occasionally approve reports from reference committees either instructing our delegates to the A.M.A. or hamstringing their freedom of action in the exercise of their intellectual integrity on any motion or proposition before the House of Delegates of the A.M.A.

Today you have already passed one resolution that is going to be very embarrassing to the delegates of this Society to the A.M.A. You are about to pass a resolution in which it says in general anything that is not good you shall vote against without bringing out upon the floor here the specific thing to which it is aimed and upon which you are endeavoring to instruct your delegates, of whom I am one. If this resolution passes, I shall still have to read the Bible to find out what is really meant as to who and what is the nefarious thing that I should protest against. Let us hope, at least, that the delegates of the A.M.A. from the rest of the states have as high a zeal for ethical conduct as we have ourselves. On the other hand, if there is pending, and if anybody knows of, a specific proposition upon which you want to instruct us, your delegates, say so. (Applause)

SPEAKER BAUER: Is there any other discussion? If not, you have before you the report of the reference committee which recommends adoption of the resolution.

DR. HARRY ARANOW, Bronx: I believe the other resolution which the chairman of the reference committee says deals with the same subject matter in more detail may throw some light upon the discussion of this resolution. May we take up that other resolution now and hold this in abeyance for the time being.

SPEAKER BAUER: Do you so move?

DR. ARANOW: Yes, I will move that

DR. JOHN L. BAUER, *Kings*: I will second that.

SPEAKER BAUER: It has been moved that the other resolution pertaining to this subject-matter be taken up before final action is taken on the resolution just read. Is there any discussion?

... There were calls for the question, and the motion was put to a vote, and was unanimously carried. . . .

SPEAKER BAUER: We will take up the other resolution first, and then come back to this one

Section 42. (See 18)

Report of Reference Committee on New Business C—Opposition to Change in A.M.A. Rule of Ethics Against Consultation with Nonmedical Persons

DR. GUESS: This is the resolution referred to that was presented by Dr Irl H Blaisdell, secretary of the Syracuse Eye, Ear, Nose, and Throat Club:

"WHEREAS, there is a Rule of Ethics governing the relationship of members of the American Medical Association in the matter of giving lectures or courses of instruction or to consult with anyone not associated with actual medical service, adopted by the House of Delegates of the American Medical Association in 1935; and

"WHEREAS, this Rule of Ethics in the opinion of this organization is still satisfactory and adequate, and

"WHEREAS, the motion passed at the 1941 meeting of the Section on Ophthalmology of the American Medical Association in Cleveland asking the House of Delegates to rescind this motion was not adequately discussed, and

"WHEREAS, the one hundred and fifty members present did not fully represent the opinions of this organization; be it

"Resolved, that it is the opinion of this organization, the Syracuse Eye, Ear, Nose, and Throat Club, that the Rule of Ethics established in 1935 by vote of the House of Delegates not be rescinded; and be it

"Resolved, that the Secretary be instructed to convey a copy of these resolutions to the delegates of the New York State Medical Society to the House of Delegates of the American Medical Association and such others as may be advisable; namely, the President of the American Academy of Ophthalmology, Dr. Ralph I. Lloyd, of Brooklyn, New York, and the Secretary of the Ophthalmological Section of the American Medical Association, Dr. Derrick Vail, of Cincinnati, Ohio."

The committee believes the purpose of this resolution has been adequately covered by the resolution of Dr. Bedell and, therefore, believes that it is unnecessary to bring it before the House at this time, although the purpose has been approved by the committee.

Mr. Speaker, I think that Dr. Bedell, who is the prime mover of this, could enlighten us a lot on the conditions which are existing and which might be contrary to the welfare of the medical profession.

SPEAKER BAUER: Dr. Bedell, the chairman would be very glad to have you come up here and explain this in more detail.

DR ARTHUR J. BEDELL, *Past-President* Mr Speaker and Members of the House, I regret that Dr Kopetzky's knowledge is so limited that he will have to refer to the Bible for his spiritual education

I refer particularly to the final portion of my resolution, "that the delegates from the Medical Society of the State of New York to the American Medical Association be instructed to oppose any and every attempt to lower the standing of medical practice or conduct"

That is certainly clear to anyone who wishes to have it clear—"to oppose any and every attempt to lower the standing of medical practice or conduct" This organization has gone on record as approving certain rules of conduct. Among those rules are that we do not consult with those who are not engaged in the practice of medicine There is not a man on the floor who does not know that it is unethical to consult with an osteopath *

I am sorry to have to go into this in detail, but let us go back, so if you are asked to vote on a specific question—incidentally, this resolution was not for a specific purpose, but the question has been raised that it is—you will know the background In 1934 or 1935 there was a great deal of agitation regarding the consultations and the fee-splitting between ophthalmologists and opticians Every one of you knows how that has been spread through the literature in the country You know the article in *Fortune* You know all that that has led to A certain individual, a professor of ophthalmology in a western university, and the attending ophthalmologist in a hospital, came before the Section on Ophthalmology, and asked that the Section go on record as disapproving instruction by doctors of laymen—and opticians and optometrists are laymen in our sense It came about then that this resolution was passed by the Section, and passed by an overwhelming vote It was then carried to the House of Delegates of the American Medical Association, and they approved it unanimously.

Subsequent to that, some very few felt that that curtailed their activities in one way or another, so they started a campaign for the rescinding of this resolution. As a result, a referendum vote was sent to every registered ophthalmologist in the Section on Ophthalmology of the American Medical Association, and much to the surprise of those that sponsored that referendum the vote was overwhelmingly in favor of the retention of it. Please take that in note that instead of any small group, it was sent to all registered members of the Section on Ophthalmology, and an overwhelming vote came back, "Do not rescind it"

That was not sufficient for those who wished for some motives to change it, so they brought it up before the Section on Ophthalmology, and again they were defeated. Finally, at the last meeting, late in the afternoon, someone arose and said, "I move we go into executive session" At that time the House was almost empty—well, certainly, there was less than one-tenth of the number of men that had been there. The resolution for rescinding was then placed before this

* Should be "chiropractor," according to later correction

small crowd, and, by about eight votes, was then passed. That is the history of the movement.

In my pocket upstairs—unfortunately not on my person—is a letter from the secretary of the Section on Ophthalmology. (For those who do not know it, I happen to be the delegate to the American Medical Association representing the Section on Ophthalmology of the A.M.A.) As I said, I have a letter from the section chairman saying, "Do not introduce that rescinding resolution until you hear more from us. Further, there will be a meeting of the Section before action will be taken."

Let us understand what that means. There has been a nation-wide rising up in wrath and indignation against this rescinding resolution, and that has come from all over the country. It has come from the West Coast, the Middle States, and so on. If you pass the resolution which your committee approved of, it simply says you are going to oppose any and every attempt to lower the standards of medical practice or conduct. I sincerely trust you will not think there is any hidden motive, for there is not. (Applause)

SPEAKER BAUER: I think for clarification that perhaps some misunderstanding exists in this House as to the intent of this resolution. As the chair understands it—and if I am wrong, Dr. Guess, please correct me—this is not a resolution directing our delegates to take a resolution to the American Medical Association and introduce it, but merely that if such a resolution as has been described is introduced by anyone else, they are instructed to oppose it. Am I correct in that?

DR. GUESS: Right.

SPEAKER BAUER: Is there any further discussion?

DR. JOHN J. MASTERSON, Kings: Dr. Bedell made a statement that it was not ethical to consult with an osteopath. Does he mean an osteopath or a chiropractor? An osteopath is licensed to practice in this state.

DR. BEDELL: Thank you! I mean a chiropractor.

DR. MASTERSON: I brought that before you because we have the press here.

PRESIDENT KOPETZKY: I did not understand it, as it has now been presented.

CHORUS: Nor did we.

DR. GUESS: Inasmuch as Dr. Kopetzky and several others have said they did not understand it, I should like to read Dr. Bedell's resolution again.

SPEAKER BAUER: Please do so.

DR. GUESS: It reads:

"WHEREAS, it has come to our attention that resolutions may be introduced in the House of Delegates of the American Medical Association which we believe will lower the ethical standing of the members of the profession; and

"WHEREAS, we are convinced that any attempt to so alter the professional standing of our members would be detrimental to the public health; be it therefore

"Resolved, that the House of Delegates of the Medical Society of the State of New York, in annual session assembled, hereby registers its protest of any such contemplated changes; and further be it

"Resolved, that the delegates from the Medi-

cal Society of the State of New York to the American Medical Association be instructed to oppose any and every attempt to lower the standing of medical practice or conduct."

The committee recommends approval of this resolution, and I so move.

SPEAKER BAUER: It has already been moved. It was also moved that action on this be delayed until the other resolution was presented. No motion was made with reference to the other resolution of Dr. Blaisdell's, so the motion before the House now is still the original motion to adopt the report of the reference committee, which carries with it approval of the resolution introduced by Dr. Bedell.

DR. ABRAHAM KOPLOWITZ, Kings: I am in entire sympathy with Dr. Bedell in his ideas, but I do not think that this resolution is in any way going to further them. This is instructing the delegates to do a very obvious thing, a thing which if they did not think of they have no right to be delegates. I would suggest or, rather, move you that this be resubmitted to the reference committee with very definite instructions as to the wording of the resolution to make it apply to the particular rescinding that Dr. Bedell speaks of. After there is a rewording of that, we could then take a definite stand.

.... The motion was seconded by several.

SPEAKER BAUER: It has been moved and seconded that the resolution introduced by Dr. Bedell be recommitted to the reference committee. Is there any discussion on the recommitment?

DR. JAMES F. ROONEY, Past-President: I can see no reason for recommitting the resolution. It merely calls attention to the need for our delegates to the A.M.A. to stand for the preservation of our present Code of Ethics. It may seem to some superfluous, but it does not seem so to me. I feel that the resolution is perfectly proper, and in view of Dr. Bedell's lucid explanation not alone is it proper, but it is needed at this time. I hope the motion to resubmit will not pass and that the House will vote to sustain the Code of Ethics of the A.M.A., and will so direct our delegates to that body.

.... The question being called, the motion to recommit was put to a vote, and was lost.

SPEAKER BAUER: The motion before you now is the adoption of the reference committee's report, which carries with it adoption of Dr. Bedell's resolution. Is there any further discussion?

.... The question being called, the motion was put to a vote, and was carried.

DR. GUESS: We will now go back to the other resolution by Dr. Blaisdell on the same subject. Shall I re-read it?

CHORUS: No!

SPEAKER BAUER: Does anyone wish that second resolution re-read?

CHORUS: No!

SPEAKER BAUER: It is the wish of the House not to have it re-read.

DR. GUESS: The reference committee believes the purpose of this resolution has been adequately covered by the resolution of Dr. Bedell and, therefore, believes that it is unnecessary to bring it before the House at this time, although the purpose has been approved by the committee.

DR. ARANOW: Yes, I will move that.

DR. JOHN L. BAUER, *Kings*: I will second that.

SPEAKER BAUER: It has been moved that the other resolution pertaining to this subject-matter be taken up before final action is taken on the resolution just read. Is there any discussion?

.... There were calls for the question, and the motion was put to a vote, and was unanimously carried.

SPEAKER BAUER: We will take up the other resolution first, and then come back to this one.

Section 42. (See 18)

Report of Reference Committee on New Business C—Opposition to Change in A.M.A. Rule of Ethics Against Consultation with Nonmedical Persons

DR. GUESS: This is the resolution referred to that was presented by Dr. Irl H. Blaisdell, secretary of the Syracuse Eye, Ear, Nose, and Throat Club:

"WHEREAS, there is a Rule of Ethics governing the relationship of members of the American Medical Association in the matter of giving lectures or courses of instruction or to consult with anyone not associated with actual medical service, adopted by the House of Delegates of the American Medical Association in 1935; and

"WHEREAS, this Rule of Ethics in the opinion of this organization is still satisfactory and adequate; and

"WHEREAS, the motion passed at the 1941 meeting of the Section on Ophthalmology of the American Medical Association in Cleveland asking the House of Delegates to rescind this motion was not adequately discussed; and

"WHEREAS, the one hundred and fifty members present did not fully represent the opinions of this organization; be it

"Resolved, that it is the opinion of this organization, the Syracuse Eye, Ear, Nose, and Throat Club, that the Rule of Ethics established in 1935 by vote of the House of Delegates not be rescinded; and be it

"Resolved, that the Secretary be instructed to convey a copy of these resolutions to the delegates of the New York State Medical Society to the House of Delegates of the American Medical Association and such others as may be advisable; namely, the President of the American Academy of Ophthalmology, Dr. Ralph I. Lloyd, of Brooklyn, New York, and the Secretary of the Ophthalmological Section of the American Medical Association, Dr. Derrick Vail, of Cincinnati, Ohio."

The committee believes the purpose of this resolution has been adequately covered by the resolution of Dr. Bedell and, therefore, believes that it is unnecessary to bring it before the House at this time, although the purpose has been approved by the committee.

Mr. Speaker, I think that Dr. Bedell, who is the prime mover of this, could enlighten us a lot on the conditions which are existing and which might be contrary to the welfare of the medical profession.

SPEAKER BAUER: Dr. Bedell, the chairman would be very glad to have you come up here and explain this in more detail.

DR. ARTHUR J. BEDELL, *Past-President*: Mr. Speaker and Members of the House, I regret that Dr. Kopetzky's knowledge is so limited that he will have to refer to the Bible for his spiritual education.

I refer particularly to the final portion of my resolution, "that the delegates from the Medical Society of the State of New York to the American Medical Association be instructed to oppose any and every attempt to lower the standing of medical practice or conduct."

That is certainly clear to anyone who wishes to have it clear—"to oppose any and every attempt to lower the standing of medical practice or conduct." This organization has gone on record as approving certain rules of conduct. Among those rules are that we do not consult with those who are not engaged in the practice of medicine. There is not a man on the floor who does not know that it is unethical to consult with an osteopath.*

I am sorry to have to go into this in detail, but let us go back, so if you are asked to vote on a specific question—incidentally, this resolution was not for a specific purpose, but the question has been raised that it is—you will know the background. In 1934 or 1935 there was a great deal of agitation regarding the consultations and the fee-splitting between ophthalmologists and opticians. Every one of you knows how that has been spread through the literature in the country. You know the article in *Fortune*. You know all that that has led to. A certain individual, a professor of ophthalmology in a western university, and the attending ophthalmologist in a hospital, came before the Section on Ophthalmology, and asked that the Section go on record as disapproving instruction by doctors of laymen—and opticians and optometrists are laymen in our sense. It came about then that this resolution was passed by the Section, and passed by an overwhelming vote. It was then carried to the House of Delegates of the American Medical Association, and they approved it unanimously.

Subsequent to that, some very few felt that that curtailed their activities in one way or another, so they started a campaign for the rescinding of this resolution. As a result, a referendum vote was sent to every registered ophthalmologist in the Section on Ophthalmology of the American Medical Association, and much to the surprise of those that sponsored that referendum the vote was overwhelmingly in favor of the retention of it. Please take that in note: that instead of any small group; it was sent to all registered members of the Section on Ophthalmology, and an overwhelming vote came back, "Do not rescind it."

That was not sufficient for those who wished for some motives to change it, so they brought it up before the Section on Ophthalmology, and again they were defeated. Finally, at the last meeting, late in the afternoon, someone arose and said, "I move we go into executive session." At that time the House was almost empty—well, certainly, there was less than one-tenth of the number of men that had been there. The resolution for rescinding was then placed before this

* Should be "chiropractor," according to later correction.

small crowd, and, by about eight votes, was then passed. That is the history of the movement.

In my pocket upstairs—unfortunately not on my person—is a letter from the secretary of the Section on Ophthalmology. (For those who do not know it, I happen to be the delegate to the American Medical Association representing the Section on Ophthalmology of the A.M.A.) As I said, I have a letter from the section chairman saying, "Do not introduce that rescinding resolution until you hear more from us. Further, there will be a meeting of the Section before action will be taken."

Let us understand what that means. There has been a nation-wide rising up in wrath and indignation against this rescinding resolution, and that has come from all over the country. SPEAKER BAUER: It is the wish of the House not to have it re-read.

DR. GUESS: The reference committee believes the purpose of this resolution has been adequately covered by the resolution of Dr. Bedell and, therefore, believes that it is unnecessary to bring it before the House at this time, although the purpose has been approved by the committee.

DR. ARANOW: Yes, I will move that.

DR. JOHN L. BAUER, *Kings*: I will second that.

SPEAKER BAUER: It has been moved that the other resolution pertaining to this subject-matter be taken up before final action is taken on the resolution just read. Is there any discussion?

.... There were calls for the question, and the motion was put to a vote, and was unanimously carried.

SPEAKER BAUER: We will take up the other resolution first, and then come back to this one.

Section 42. (See 18)

Report of Reference Committee on New Business C—Opposition to Change in A.M.A. Rule of Ethics Against Consultation with Nonmedical Persons

DR. GUESS: This is the resolution referred to that was presented by Dr. Irl H. Blaisdell, secretary of the Syracuse Eye, Ear, Nose, and Throat Club:

"WHEREAS, there is a Rule of Ethics governing the relationship of members of the American Medical Association in the matter of giving lectures or courses of instruction or to consult with anyone not associated with actual medical service, adopted by the House of Delegates of the American Medical Association in 1935; and

"WHEREAS, this Rule of Ethics in the opinion of this organization is still satisfactory and adequate; and

"WHEREAS, the motion passed at the 1941 meeting of the Section on Ophthalmology of the American Medical Association in Cleveland asking the House of Delegates to rescind this motion was not adequately discussed; and

"WHEREAS, the one hundred and fifty members present did not fully represent the opinions of this organization; be it

"Resolved, that it is the opinion of this organization, the Syracuse Eye, Ear, Nose, and Throat Club, that the Rule of Ethics established in 1935 by vote of the House of Delegates not be rescinded; and be it

"Resolved, that the Secretary be instructed to convey a copy of these resolutions to the delegates of the New York State Medical Society to the House of Delegates of the American Medical Association and such others as may be advisable; namely, the President of the American Academy of Ophthalmology, Dr. Ralph I. Lloyd, of Brooklyn, New York, and the Secretary of the Ophthalmological Section of the American Medical Association, Dr. Derrick Vail, of Cincinnati, Ohio."

The committee believes the purpose of this resolution has been adequately covered by the resolution of Dr. Bedell and, therefore, believes that it is unnecessary to bring it before the House at this time, although the purpose has been approved by the committee.

Mr. Speaker, I think that Dr. Bedell, who is the prime mover of this, could enlighten us a lot on the conditions which are existing and which might be contrary to the welfare of the medical profession.

SPEAKER BAUER: Dr. Bedell, the chairman would be very glad to have you come up here and explain this in more detail.

DR. ARTHUR J. BEDELL, *Past-President*: Mr. Speaker and Members of the House, I regret that Dr. Kopetzky's knowledge is so limited that he will have to refer to the Bible for his spiritual education.

I refer particularly to the final portion of my resolution, "that the delegates from the Medical Society of the State of New York to the American Medical Association be instructed to oppose any and every attempt to lower the standing of medical practice or conduct."

That is certainly clear to anyone who wishes to have it clear—"to oppose any and every attempt to lower the standing of medical practice or conduct." This organization has gone on record as approving certain rules of conduct. Among those rules are that we do not consult with those who are not engaged in the practice of medicine. There is not a man on the floor who does not know that it is unethical to consult with an osteopath.*

I am sorry to have to go into this in detail, but let us go back, so if you are asked to vote on a specific question—incidentally, this resolution was not for a specific purpose, but the question has been raised that it is—you will know the background. In 1934 or 1935 there was a great deal of agitation regarding the consultations and the fee-splitting between ophthalmologists and opticians. Every one of you knows how that has been spread through the literature in the country. You know the article in *Fortune*. You know all that that has led to. A certain individual, a professor of ophthalmology in a western university, and the attending ophthalmologist in a hospital, came before the Section on Ophthalmology, and asked that the Section go on record as disapproving instruction by doctors of laymen—and opticians and optometrists are laymen in our sense. It came about then that this resolution was passed by the Section, and passed by an overwhelming vote. It was then carried to the House of Delegates of the American Medical Association, and they approved it unanimously.

Subsequent to that, some very few felt that that curtailed their activities in one way or another, so they started a campaign for the rescinding of this resolution. As a result, a referendum vote was sent to every registered ophthalmologist in the Section on Ophthalmology of the American Medical Association, and much to the surprise of those that sponsored that referendum the vote was overwhelmingly in favor of the retention of it. Please take that in note: that instead of any small group, it was sent to all registered members of the Section on Ophthalmology, and an overwhelming vote came back, "Do not rescind it."

That was not sufficient for those who wished for some motives to change it, so they brought it up before the Section on Ophthalmology, and again they were defeated. Finally, at the last meeting, late in the afternoon, someone arose and said, "I move we go into executive session." At that time the House was almost empty—well, certainly, there was less than one-tenth of the number of men that had been there. The resolution for rescinding was then placed before this

* Should be "chiropractor," according to later correction.

their practices, and if government agencies refuse to commission in the Armed Services graduates of foreign schools, both natives and foreigners who are refugees here, the result will be that these graduates of foreign schools will have the practice, whatever there is of it, by the time our native sons return from military duty. On the other hand, it should be honestly stated that most of these men are knocking at the door of government agencies and offering their services to the government because they realize the peculiar position in which conflicting and multitudinous regulations place them, and they do not wish to assume the role of displacing the native-born American physician. Consequently, some time ago I wrote a memorial on their situation to the President of the United States and asked that some government agency formulate a policy which would, on the one hand, utilize their services, and on the other hand not put them into the classification of displacing American physicians who are out on government service in the military forces, to prevent inter-racial and inter-religious hatreds.

This memorial that I sent forward has been passing through various departments in Washington, and has not as yet been officially answered. Unofficially, I have heard from Dr. Irving Abell, the chairman of the National Committee that sits on the committees with the Surgeons General of the Army and Navy and the Public Health, that they are trying to work out a formula. The action of Surgeon General Parran's editorial, to which reference is made in the resolution, was a kite, to see the reaction, and in essence it meant that they recognize the danger of leaving these men to assume the practices of Americans who go into the Armed Forces and the natural reaction of our native-born doctors who, when they come back, will find this competition seated and entrenched and have a harder job re-establishing themselves. They recognize that as a potent factor and tried to find a way of utilizing these men's services away from New York, and they ask states which have not as liberal a policy in regard to licensure as New York State has to let down the bars, because if they did these men would not be crowding by the thousands in the State of New York but would spread all over the country. They merely ask that these states let down the bars temporarily while these men are in government service, not in the Army, because in the Armed Forces, for reasons of strategy and policy, these men cannot be commissioned and cannot be used; hence this effort.

This effort is indirectly a service to our own people. This effort indirectly is taking these men, these unfortunate men, whom when we return from service we will envy because they will have seated themselves into our practices, out of such a precarious position. In other words, they, too, will leave their home stations and take their chances to re-establish themselves when and if the emergency is over. Inherent in the thing is the fact that they have a temporary license to practice in a specific place. For instance, they may get a temporary license to practice in Sitka, Alaska, on a government project, while the emergency is on and for six months thereafter, and when that period is over they can come back at the same time as our American doctors come back from the Armed Forces.

Thus there is behind the program the essence of what we want, namely, its demobilization after the war. That is the situation. Procurement and Assignment insists that they enroll. Procurement and Assignment will then assign them for temporary work with the Public Health Service or for civilian work away from home. That is all there is to it.

DR. J. RICHARD KEVIN, *Past-President*: I move we lay this on the table.

DR. KOPLOWITZ: I second the motion.

.... The motion to table was put to a vote, and was lost....

DR. JAMES F. ROONEY, *Past-President*: In connection with the memorial which Dr. Kopetzky has just spoken about, the Congress in the last two weeks has taken some action on this question relating to the admission of aliens into the Army. There has never been any provision in the statute law of the United States which prevents any alien from being commissioned in the Army. He could not be paid, but he could be commissioned. Two weeks ago both houses, the Senate and the House of Representatives, passed a bill providing that aliens otherwise acceptable to the government for commission in the Armed Services could be commissioned and paid. Whether that bill has been signed by the President or not, I am not yet informed. My information is from the official Army and Navy Journal, so I take it something is already being done in relation to admitting these men to the Army and eventually in all probability some will be admitted. Of course not all will be, but many of them who are crying that they want to be commissioned may be, and the other services may take this up. I felt the House should know that has already been done. The Navy in all probability will not accept them. The Navy never has, but the other services I believe very shortly will. They are going to be needed, and they will probably be utilized where they can best be fitted in.

PRESIDENT KOPETZKY: I want to make a correction of Dr. Rooney's statement. I am referring to men who have taken out their first papers and have been here for some time; not to a nondeclarant personage who lives in this country and was admitted under the quota, which is in a strict sense what an alien is.

DR. ROONEY: It does not make any difference now.

PRESIDENT KOPETZKY: The ones I have reference to are not in the strict sense of the word aliens under the law.

.... The question was called for, and the motion was put to a vote, and was adopted....

Section 44. (See 22)

Report of Reference Committee on New Business C—Licensure, Full Citizenship Requirement

DR. GUESS: This is a resolution presented by Dr. John L. Edwards, of Columbia County, Dr. Denver N. Vickers, of Washington County, and Dr. Joseph H. Cornell, of Schenectady County:

"WHEREAS, the large influx of foreign-educated physicians permitted to practice medicine in this state without known scholastic and medical training has tended to lower the standards of medical ethics and practice;

"Resolved, that applicants for the practice of medicine in this state from foreign schools

SPEAKER BAUER: What is your recommendation, that no action be taken on it?

DR. GUESS: No, it can be brought before the House, but we make no comment on it.

DR. ROONEY: I move that that lay on the table.

....The motion was seconded, put to a vote, and was carried.....

Section 43. (See 24)

Report of Reference Committee on New Business C—Foreign Physicians Under Procurement and Assignment

DR. GUESS: This resolution was introduced by Dr. John D. Carroll, of the Medical Society of the County of Rensselaer:

"Resolved that the Delegates representing the Medical Society of the County of Rensselaer of the State of New York put forward this resolution:

"Pursuant to Surgeon General Parran's editorial of recent date in the *Journal of the American Medical Association*, concerning the shortage of medical practitioners throughout the country and advocating the lessening of licensure restrictions in the case of foreign physicians, we of the Medical Society of the County of Rensselaer respectfully submit:

"Resolved that (1) Since the majority of said foreign doctors are engaged in the practice of medicine in the State of New York, the Office of Procurement and Assignment shall in the future select from among these same foreign doctors now practicing in this state physicians for practice in other states that meet with New York State's reciprocity laws;

"(2) All foreign physicians who have been licensed to practice in the United States be brought under the jurisdiction of the Procurement and Assignment Board and, if they are not eligible for Army or Navy duty, they shall be placed in other governmental service for the duration of the war."

The committee recommends approval of this resolution, and I so move.

....The motion was seconded.....

DR. LAURANCE D. REDWAY, Westchester: It is my understanding that the Procurement and Assignment Service has no authority whatever to assign anybody any place anywhere but merely to furnish material to be assigned by the service generally. If I am correct in that, I cannot see how this motion can be entertained for the approval of this resolution.

SPEAKER BAUER: Maybe Colonel Kopetzky could enlighten us.

A question has been raised in reference to this resolution (handing Colonel Kopetzky a copy of Dr. Carroll's resolution) as to whether or not the Procurement and Assignment Service has any authority to assign any physician anywhere, or whether theirs is purely an informative function, namely, getting the necessary information and availability of an individual for such assignment.

PRESIDENT KOPETZKY: Procurement and Assignment catalogues physicians according to their capabilities and their availability. In estimating availability, it asks the institutions where they are working, it asks competent committees in the communities where they practice, and, lastly, if they are connected with teaching institutions or

state health departments, how they rate them. Then all that information goes to Procurement and Assignment, and they assign the man on requisitions of various agencies, the Army, the Navy, the Panama Service, the Indian Service, full-time Civil Service, full-time civilian defense, etc., according to the requisitions coming in from these agencies for doctors.

SPEAKER BAUER: Thank you, Doctor!

Apparently the point made by Dr. Redway was in order.

DR. WALTER P. ANDERTON, New York: What states reciprocate with New York State in the licensure of physicians?

DR. GUESS: There is no reciprocity that I know of.

DR. ROONEY: There is no reciprocity of New York with any other state in the Union.

SPEAKER BAUER: In view of the points which have been raised, I think if there is no objection we will recommend the resolution for redrawing.

DR. GUESS: In all fairness to the committee, let me say that we realized there is no reciprocity of New York State with any other state in the Union, but Procurement and Assignment has nothing to do with reciprocity. When that begins to work, it will not be necessary to have reciprocity for the man to practice in the other state.

CHORUS: Read it again!

SPEAKER BAUER: Will you read that again? Some of them apparently did not hear it or wish it read again.

DR. GUESS: The resolution reads:

"Pursuant to Surgeon General Parran's editorial of recent date in the *Journal of the American Medical Association*, concerning the shortage of medical practitioners throughout the country and advocating the lessening of licensure restrictions in the case of foreign physicians, we of the Medical Society of the County of Rensselaer respectfully submit:

"Resolved that (1) Since the majority of said foreign doctors are engaged in the practice of medicine in the State of New York, the Office of Procurement and Assignment shall in the future select from among these same foreign doctors now practicing in this state physicians for practice in other states that meet with New York State's reciprocity laws;"

We have no reciprocity, so that would have to be deleted, but according to the intent of the resolution, applying it to the Procurement and Assignment it seems to be irrelevant anyway, so we could delete the clause "that meet with New York State's reciprocity laws," and not affect it in any way.

"(2) All foreign physicians who have been licensed to practice in the United States be brought under the jurisdiction of the Procurement and Assignment Board and, if they are not eligible for Army or Navy duty, they shall be placed in other governmental service for the duration of the war."

PRESIDENT KOPETZKY: Gentlemen, if there is one group in the community who are between the devil and the deep sea it is the foreign physician. National Headquarters says it is a New York problem. If our native sons are put into the service, and if our native sons must leave

ten years in a foreign country, and has since come to this country—if you want him to do nothing for five years, waiting for citizenship, you are either going to drive him into illicit practice or you are going to make him a recipient of relief, whether it be official or nonofficial, direct or indirect, and some other part of the community will have to support him.

Don't forget one other factor, gentlemen. The Medical Practice Act was not intended to act as a bar to any qualified man to practice medicine. It was enacted with the idea of protecting the community from illicit, unqualified practitioners, and I believe sooner or later by injudicious action of the medical profession itself that differentiation, and decision, and interpretation will have to be made. You will force it into the courts, and then these ancillary regulations that the Regents are making to protect us from the quantity of men who enter practice rather than protect us from the quality of men who enter practice will be decided by our courts.

As far as my weak voice can influence you, I would suggest in the interests of the Regents as well as in the interests of this State Society and its dignity that we should leave this question alone.

DR. HOMER J. KNICKERBOCKER, *Ontario*. I move we table the matter.

The motion was seconded by several.

SPEAKER BAUER: It has been moved and seconded that the resolution be tabled. All those in favor of tabling it say "Aye"; those opposed, "No." Apparently the motion is lost, but the chair will call for a rising vote. All those in favor of tabling the resolution will please rise.

Eighty-one arose.

SPEAKER BAUER: Now those opposed to tabling the resolution will please rise.

Sixty-three arose.

SPEAKER BAUER: The motion is tabled by a vote of eighty-one to sixty-three. (Applause)

Section 45

Report of Reference Committee on Report of the Council—Part VI: Medical Relief

DR. ROY B. HENLINE, *New York*. Your committee wishes to compliment the Subcommittee on Medical Relief, of which Dr. E. Christopher Wood is chairman, on the tremendous progress it has made toward the solution of this difficult problem of medical relief, and approve their report as published. The principles governing working arrangements between the medical profession and the Departments of Public Welfare have been previously reported. During the past year many conferences and discussions have led to a joint statement by the Subcommittee on Medical Relief and the Departments of Public Welfare outlining their progress. Through the combined efforts of these two agencies the medical care plan has been instituted in our state.

Under the general principles set forth, great strides have been made in procuring good medical care of all types for persons on relief, only through the complete understanding and cooperation of the Subcommittee on Medical Relief of the Medical Society of the State of New York in conjunction with the Departments of Public Welfare. This work has not yet been completed, and, through wider experience, many of the path-

ways for this service may have to be altered. There are still many features which are not completely desirable to either group, but they have accomplished much through their cooperation and understanding and willingness to sacrifice many of these controversial points for the general good of the patient. It is hoped that this work can continue under their competent leadership. We wish to commend Deputy Commissioner Lee C. Dowling and Dr. H. Jackson Davis for their splendid cooperation with the Medical Society of the State of New York. It is suggested that attention of the membership be called to a Special Article on "New York State's Public Medical Care Program," which will appear in the May 1, 1942, issue of the *State Journal*.

I move the approval of the complete report.

The motion was seconded.

SPEAKER BAUER: You have heard the report of the reference committee. It has been moved and seconded that it be adopted. Is there any discussion?

DR. ARTHUR J. BEDELL, *Past-President*. A question of information—I would like a little information regarding the record of this man Davis that is specifically recommended for his activities because, if my memory serves me well, it might be illuminating for this organization to understand whom they are recommending today.

SPEAKER BAUER: Dr. Wood, would you like to answer that question?

DR. E. CHRISTOPHER WOOD, *Westchester*. I would like to have the chairman of the reference committee re-read that portion. I am not sure I remember the wording.

DR. HENLINE: "We wish to commend Deputy Commissioner Lee C. Dowling and Dr. H. Jackson Davis for their splendid cooperation with the Medical Society of the State of New York."

DR. WOOD: In answer to Dr. Bedell's question, I interpret that to mean that the committee commends the cooperation of these two men in working out whatever solution we have so far obtained, and does not refer to, shall we say, the past record of either of these men.

DR. BEDELL: I move you, sir, as a substitute that we recommit this portion of the report for further clarification before action is taken on it.

The motion was seconded.

SPEAKER BAUER: It has been moved and seconded that this portion of the report be re-committed.

SECRETARY IRVING: It so happens that I have had the privilege of sitting in with Dr. Wood's committee and representatives of the State Department of Social Welfare throughout the last two years in all this work. I can state without the slightest reservation that the cooperation of those two men has been during that time excellent, and that is all that I understand the commendation of the reference committee indicates. I do not think it needs to be re-committed.

SPEAKER BAUER: Is there any further discussion?

The question was called for, and the motion to recommit was put to a vote, and was lost.

SPEAKER BAUER: The report is before you for your consideration as to its adoption. Is there any further discussion?

other than Canada be required to have full citizenship, premedical and medical education comparable with class A medical schools of the United States and Canada."

The committee, Mr. Speaker, wishes to bring this before the House of Delegates by paragraph, or in two parts.

Paragraph 1—the committee is agreed and recommends a vote be taken on this paragraph at this time.

SPEAKER BAUER: Will you read that paragraph again, please?

DR. GUESS: It reads:

"WHEREAS, the large influx of foreign-educated physicians permitted to practice medicine in this state without known scholastic and medical training has tended to lower the standards of medical ethics and practice;"

SPEAKER BAUER: Well, what about it?

DR. GUESS: We move the adoption of that paragraph.

DR. GEORGE S. TOWNE, *Saratoga*: I second the motion.

SPEAKER BAUER: I think the motion is out of order in that you cannot adopt a preamble to a resolution before you adopt the resolution itself. You can adopt the resolution and then modify the preamble to suit the resolution, but if you adopt the preamble first, then you may have adopted something that may have no bearing at all on the body of the resolution.

DR. J. RICHARD KEVIN, *Past-President*: We have no power to suggest to the Regents to modify their requirements that I know of.

CHORUS: We have.

SPEAKER BAUER: I will rule that motion out of order, Dr. Guess. Do you want to go on to the resolution itself?

DR. GUESS: Paragraph 2—after prolonged and considerable discussion the committee believes that this paragraph, deleting the reference to Canada, be brought to a vote of the House of Delegates without comment.

SPEAKER BAUER: Will you read the paragraph involved so it may be clear in the minds of the House?

DR. GUESS: The second paragraph reads:

"Resolved: That applicants for the practice of medicine in this state from foreign schools other than Canada be required to have full citizenship, premedical and medical education comparable with class A medical schools of the United States and Canada."

SPEAKER BAUER: The committee makes no recommendation except to delete the words with reference to Canada. Is that correct?

DR. GUESS: Right.

SPEAKER BAUER: There is no motion before the House.

DR. JOHN L. EDWARDS, *Columbia*: I move it be adopted.

SPEAKER BAUER: Do you move the adoption with the deletion of the words with reference to Canada?

DR. EDWARDS: I do.

.... The motion was seconded by several....

DR. HARRY ARANOW, *Bronx*: I would like to know from Dr. Lawrence whether or not this will require a change in the state law.

SPEAKER BAUER: Dr. Lawrence, can you answer that question?

DR. JOSEPH LAWRENCE: What was the question?

SPEAKER BAUER: The question was whether or not the adoption of this resolution as moved would require a change in the state law.

DR. LAWRENCE: It would.

SPEAKER BAUER: Does that answer your question?

DR. ARANOW: Yes.

SPEAKER BAUER: Is there any other question, or any other discussion?

DR. JAMES F. ROONEY, *Past-President*: I hate to disagree with my good friend, Dr. Lawrence, but in this case I do disagree with him. I don't think it does embody any special change in the state law; it embodies a change in the regulations of the Board of Regents. The resolution requires citizenship, and that will embody a change in the law, but the remainder of it will require no change in the basic law.

DR. ALFRED HELLMAN, *New York*: I should like to move a substitute resolution as follows: That the resolution as read be adopted omitting the word "Canada" and omitting the requirement of full citizenship.

CHORUS: No.

SPEAKER BAUER: Dr. Hellman has moved a substitute motion, or really an amendment to the motion by deleting the requirement of full citizenship. Is that seconded?

.... There was no response....

SPEAKER BAUER: There is no second to your motion, Dr. Hellman, so it is lost.

Is there any further discussion of the motion?

PRESIDENT KOPETZKY: I am sorry that Dr. Madill is not present. We have had this kind of a resolution before in this House. I well realize the emotional reaction which is back of the resolution and back of the recommendations of the committee, and I am totally unconcerned whether you pass it under this emotional reaction or whether you do not. But this, please, remember: If you insist on citizenship for these men, some politician who wants to find a cause to reach the headlines will use that as a platform, and, as Dr. Madill said here when such a motion was pending—I think last year and also the year before—you will open the Medical Practice Act, involving citizenship and a whole lot of other questions, in your state legislature, which under an emotional reaction will not be to the best interests of the practicing physicians.

There are a limited number of men who have come in under our laws. The Regents up to date have insisted on giving every one of them an examination. There is no more endorsement of licensure. During the war period immigration has stopped. Your problem is no larger than the quota of these men that are now before you. These are facts that you should remember, and also bear in mind that it is through no fault of theirs that they are here. It is no fault of theirs any more than it was the fault of my ancestors when they came here. Except those who landed at Plymouth Rock and those who were among the original Dutch settlers in New York, if you look back at all the rest who came here, at some time each one of us came just as these men came, although not driven out and totally dissociated from all worldly goods as these men were when they arrived.

A man who has been practicing eight, nine, or

DR. BEDELL: To instruct the Council as to our desire.

SPEAKER BAUER: It will not interfere with the other motion. You are correct.

DR. KLEIN: I move the *Directory* be not printed during the coming year.

DR. BEDELL: I second that.

SPEAKER BAUER: It has been regularly moved and seconded that the *Directory* be not printed during the coming year.

DR. HARRY ARANOW, *Bronx*: I think that was passed in the original motion that it be not published this year.

SPEAKER BAUER: I thought it was merely left to the discretion of the Council, without any specific instructions. The motion before you, then, is that the *Directory* be not printed during the coming year. Is there any further discussion on it?

... The question being called, the motion was put to a vote and was carried. ...

DR. KLEIN: 2. The Board of Trustees should be memorialized to effect as many savings as they can in various committees.

3. The county medical societies should be asked to discriminate between members who can and those on whom it would be a hardship to pay dues during the term of their service.

I want to explain that the committee felt that too many men, though in the service, can very well afford to pay the dues, and with such a deficit as we will be faced with, probably next year, more careful recommendations for the reduction of dues should be made by the county societies to the Council which has, I understand, the power to reduce.

SPEAKER BAUER: The resolution passed last year was to the effect that the Council in its judgment could remit dues, a part or all of the dues.

DR. KLEIN: 4. The Board of Trustees should be empowered to use some or all of the income from investments or from the reserve fund for expenditures that may not be covered by the income from dues during the year 1942.

SPEAKER BAUER: I think that that is contrary to the Bylaws. The Bylaws specifically state that all motions with reference to the expenditure of funds must be approved by the Board of Trustees. They already have that authority, and therefore I think the motion itself is out of order.

SECRETARY IRVING: Mr. Speaker, may I say a word? This House has gone on record several times about not using the income from investments but putting that back into a war chest, so that I think you would have to have the House authorize the Trustees to that effect.

SPEAKER BAUER: A resolution or motion to the effect that is the opinion of the House that the Trustees should in their discretion use this income from investments would be in order, but I think as drawn this is out of order. Do you wish to reword it in accordance with the suggestion?

DR. KLEIN: I would be glad to.

SPEAKER BAUER: The committee simply recommends that the House recommend to the Trustees that they use the income from investments, if they deem it necessary to do so.

DR. KLEIN: Yes, I so move.

... The motion was seconded, put to a vote, and was unanimously carried. ...

DR. KLEIN: Your committee wants to compliment the treasurer for a clear and concise report, and Dr. Peter Irving for his assistance to the committee; also Mr. Anderson and Dr. Winslow. I move the adoption of the report as a whole as amended.

... The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried. ...

SPEAKER BAUER: Thank you, Dr. Klein!

Section 47. (See 8)

Report of the Reference Committee on Report of the Council—Part III: School Health Program

DR. LEO F. SCHIFF, *Clinton*: Your committee has considered the report and supplementary report of the Council subcommittee on school health. We note with approval that the Council has continued its efforts as directed by the House of Delegates at the 1941 session, and share in their dissatisfaction that, notwithstanding discussions last year by the representative subcommittees of the Regents Advisory Council and of the State Medical Society, the State Department of Education has shown no disposition to make the basic changes in departmental procedure that were recommended by the State Medical Society in 1940.

We approve of the eight principles laid down on pages 641 and 642 of the report under the headings "General," "School Health Service," and "Health Education."

We recommend that the Council through its subcommittee continue its efforts to bring about the changes whereby supervision of health and health problems among children of school age be under the charge of physicians. If this cannot be achieved through the cooperation of the State Education Department, we recommend that further steps be taken, particularly efforts to bring the matter to the attention of Parent-Teachers Associations, to the bodies interested in the school health problem, and to the public in general, and if necessary through attempts to secure legislative action.

I move the adoption of this portion of the report.

... The motion was seconded, and there being no discussion, it was put to a vote and was unanimously carried. ...

DR. SCHIFF: We present the following as the minimum requirements for an adequate school health setup:

1. That it be directed by a physician of experience in these matters and with a broad viewpoint of the responsibilities of the school for the health of its pupils; and that he have authority and sympathetic cooperation of the heads of the other divisions in his department.

2. That the program cover complete health supervision of children during their school life, including not only physical examination and attention to correction of defects, but any other matters that affect health, such as the physical condition of school rooms, the relation of study hours to recreational hours, and types of recreation.

3. That these health benefits be extended equally to all children attending schools, whether under direct charge of departments of education or not.

....The question was called for, and the motion was put to a vote, and was carried.....

(A five-minute recess was taken at this point.)

SPEAKER BAUER: The House will be in order.

Section 46. (See 7)

Report of Reference Committee on the Reports of the Treasurer and Board of Trustees

DR. W. KLEIN, *Bronx*: *Report of the Board of Trustees*—Your reference committee studied the reports of the Board of Trustees. Their concern about the future financial standing of the Society is well taken. It is cheering to see that they were and are alert and have the foresight so important at this time. Their recommendations for economy to the various heads of committees was a timely and important warning.

Your committee has no comments except to congratulate them on their performances for the year. I move the adoption of this report as printed.

....The motion was seconded, and there being no discussion, it was put to a vote and was unanimously carried.....

DR. KLEIN: *Report of the Treasurer*—The yearly report of the treasurer as printed gives but scant information for a thorough study and understanding of the financial state of our organization. Unless we read these reports in conjunction with many activities during the current year and compare those with reports and activities of previous years, we are apt to fail in a proper understanding of the figures. Your committee studied the report and compared this with various activities and with a view to the future. The first item to be noted is the income. It compares well with the 1940 figures. The total income for 1940 was \$179,148, while that of 1941 was \$176,369. The difference was due to the collection of dues in arrears amounting to \$8,664 in 1940, while in 1941 income from the same source was only \$2,237. The accountant's figures show an income over expenses for the year 1941 of only \$11,517 as against \$18,982 in the previous year. The difference is more apparent than real. Our inventories compared to liabilities are more by nearly \$3,400, while there was an appreciable decline in the income from investments. The apparent rise in the Public Relations Bureau of nearly \$5,000 is not to be taken at its face value. The allocation of part of the salaries previously paid out to administration and other bureaus were charged to this activity. The District Branch Executive Committee meetings cost nearly \$400 more than in previous years. We mention these figures not to bore you but to bear in mind the constant rise in cost of management of our organization. The reason for this is the constant expansion of our activities. Your committee is anxious about the near future. Last year it was not predictable, while at this time we can safely say that the economic outlook for our Society is not cheering. Aside from many members being called to the colors who will have their dues remitted, the new graduates will be inducted in the Army and will not join with organized medicine during the duration. We will therefore have a marked reduction in income. Our estimate is that the income will be less by about \$35,000, not counting the possible

reduction in income from investments. These will certainly not be on the increase.

At Dr. Irving's suggestion this placard was made in the office, which I simply enlarged [holding it up], and which shows the comparative rise in membership from year to year for a number of years:

1928.....	11,806
1929.....	12,314
1930.....	12,812
1931.....	13,195
1932.....	13,457
1933.....	13,299
1934.....	13,417
1935.....	14,064
1936.....	14,662
1937.....	15,529
1938.....	16,177
1939.....	16,785
1940.....	17,409
1941.....	17,781

As you see, in 1941 we had 17,781 membership, and in 1928 we had 11,806. These increases will not occur during the coming year.

An attempt was made to estimate the decline in membership or the decline in income from dues membership, and this graph was made [holding it up]. However, I think it is very, very conservative, and it will come down to about 15,000 by the end of 1942.

In our present state of the nation new activities and burdens are constantly added which we as citizens and as organized medicine will not shirk. Our organization may have to undergo an economic change which is unprecedented. If we continue to sustain all activities as of the past year and the new ones added, such as Procurement and Assignment work, a saving in expenditures is an apparent improbability. There surely will be some savings in the publication bureau with a constant increase in advertising matter, but your committee fails to see where substantial reductions can be made without curtailing important activities that have taken years to bring into existence.

The treasurer's report is a fine example of well-managed business. Your committee begs to make the following recommendations:

1. The *Directory* should not be printed during the year. This will effect a saving of a number of thousands of dollars.

SPEAKER BAUER: That already has been voted on—that it is to be left to the discretion of the Council.

DR. KLEIN: We recommend that the *Directory* be not printed next year.

SPEAKER BAUER: The House has already taken action which I think makes that motion unnecessary at the present time.

DR. ARTHUR J. BEDELL, *Past-President*: Question of information—I was out of the House when the House took action on that. What was the action?

SPEAKER BAUER: The action of the House was that the *Directory* should be printed at the discretion of the Council during the emergency.

DR. BEDELL: Could we not take action on this as well?

SPEAKER BAUER: Yes, you can, if you wish to.

bursed by the Federal Government, it was brought to our attention that New York State desired to participate in these federal funds. Therefore they wished to change the method, and instead of paying the doctor directly to pay the patient directly.

I wish to bring to your attention that we, your subcommittee and the others attending this conference, were placed by this proposal in a very difficult position as to judging and forming an opinion either for or against this proposal. If we said that we were opposed to it, we would be immediately subjected to very serious judgments. First of all, it could be said that the New York State Medical Society opposed a procedure of the State Department of Social Welfare which would permit the state to receive some six, seven, or eight hundred thousand dollars from the Federal Government. Secondly, the State Society or its representative would be put in the position of saying in effect that they had no faith in the integrity of the relief client to pay his own bills. So your committee said it would go along and observe this method of payment, which it has done.

The subcommittee made every effort to inform the Society and the whole membership that it wished each county society in its locality to keep records, if possible, of just how this worked out, and requested each group to notify your subcommittee if it had objections.

We have received statements that various localities have objected to this method. We have not, however, received any definite factual material that we could present to the State Department which would show exactly upon what factual grounds these objections were based.

I would like to say now entirely from my own standpoint—because I am not certain how the subcommittee feels about this—that I feel it would be a big mistake for this Society to go on record as favoring a return to the old system of the state paying the doctor directly.

Two years ago, as I recall it, in Buffalo, we met with several representatives of the Federal Social Security Board, and at that time they were very much in favor of paying the patient for medical services because they felt that that upheld the integrity and the independence of the relief client, that it permitted him to pay his own doctor in exactly the same manner that the self-supporting population did, and that it taught him to be independent, and, in a sense, self-reliant, and to budget what money he had.

If we object to this, and if we go on record as favoring going back to the old system of paying the doctor directly, it seems to me very, very definitely that we are favoring a form of state medicine. We are favoring a procedure in which the state pays the doctor directly for medical services. The patient has no part in the financial transaction. He has no part in deciding how much or how little, perhaps, he can spend in any one month for medical services. I believe also that it is the intention of the Federal Government and also of the state government to change this resolution, and on their part to return to the system of paying the physician directly. I hope I am not being unfair, but I cannot help but believe that this return to this system of paying the doctor directly is not without motive. Therefore, I would ask of you to consider this proposal very carefully, and I trust that you will not ap-

prove a return to the indirect method of paying the physician directly.

SPEAKER BAUER: Is there any other discussion?

DR. ABRAHAM KOPLOWITZ, Kings: Mr. Speaker and Gentlemen, this resolution was offered by Kings County because the membership in our county had requested it. Various members had spoken to us personally about it, and some had written in demanding it.

It seems that the Federal Social Security Board, or whatever the agency involved is, would rather pay it to the patient than the doctor, but let us see how that works out. They limit the price they are going to pay. It is not the personal relationship between doctor and patient, so that the doctor will charge whatever he pleases or thinks he is worth. There is a certain fixed sum. The number of times he is going to call depends upon the condition. They are giving the patient money to pay the doctor, which a number of patients do not do.

DR. WOOD spoke about a motive being behind it. Of course there is a motive: to get paid for the work you do. We know the charitable organizations very often do regulate it a whole lot more clearly perhaps—let us say—than giving it to the patient. In New York City, where a great deal of money is given out for relief, a great many of you know that they get tickets to buy groceries. Well, why not give them the money? Everything is regulated. We are not asking for anything unusual. We are asking that for the service we give, for which the price is limited, we should be paid.

In what way is that degrading to the patient? I don't see that we have to worry particularly about causing any bad effect. We are asking for what is coming to us. The least we can do is to ask for it, and if we don't get it we can shut up. We are meeting economic conditions as they exist, and I don't see why we should pussyfoot around this.

SECRETARY IRVING: It is my information that for the Greater City of New York the experience up to date is that only 5 per cent have not paid the doctor.

PRESIDENT KOPETZKY: Gentlemen, you heard a number of speakers at various times warning the profession to be on guard, and I am here now again to ask you to be true to the principles that you have been reiterating for years. When it did not concern particularly the individual's pocketbook, we stood for the principle that we wanted no intervention between our patient and ourselves.

We are trying to scrutinize every measure that comes up, on which there is government money expended for medical services, with the criterion that there shall be no intervention between the patient and ourselves. The dilemma in which the Council found itself during the last year was to make the desires of the various doctors to get the money due them from the client fit in with the criterion that no second party—and that includes government—shall intervene between the doctor and the patient. Therefore, your decision this afternoon will imply a further nibbling away of a fundamental principle that you have repeatedly enunciated and that you stand for. Don't say—I don't remember the figures Dr.

I move the adoption of this portion of the report.

.... The motion was seconded, and there being no discussion, it was put to a vote and unanimously carried.

DR. SCHIFF: We approve the recommendation that Section 491 of the Education Law be altered to require that State grants to local school authorities be made on the basis of school enrollment rather than of daily attendance. The reason for this is obvious: Under the present system, many children who should stay at home are urged to attend school in order to keep up the attendance record for the purpose of increasing the State-Aid grant.

I move the adoption of this portion of the report.

.... The motion was seconded, and there being no discussion, it was put to a vote and unanimously carried.

DR. SCHIFF: As to the supplementary report of the committee, your reference committee has reviewed this report and concurs completely with the recommendations therein submitted by the special subcommittee consisting of Drs. A. Clement Silverman and William E. Ayling, disapproving of the proposal to add an hour to each school day for physical education activities. I move the adoption of the supplementary report.

.... The motion was seconded, and as there was no discussion, it was put to a vote and unanimously carried.

DR. SCHIFF: I now move the adoption of the report as a whole.

.... The motion was seconded, and as there was no discussion, it was put to a vote and unanimously carried.

Section 48. (See 29)

Report of Reference Committee on New Business B—1943 Annual Meeting, Invitation to Buffalo

DR. MASTERSON: This is a resolution from Erie County:

"WHEREAS, the 1941 Annual Meeting of the Medical Society of the State of New York was a great success in Buffalo; and

"WHEREAS, the President-Elect, George W. Cottis, is a resident of western New York; and

"WHEREAS, the Medical Society of the County of Erie would indeed deem it an honor and great pleasure to have its colleagues from the rest of the State meet in Buffalo; therefore be it

"Resolved, that the Medical Society of the County of Erie extend an invitation to the Medical Society of the State of New York to hold its 1943 Annual Meeting in Buffalo."

Our committee looks with favor upon the invitation of the Medical Society of the County of Erie to hold its 1943 Annual Meeting in Buffalo, and would recommend the Council be apprised of our action.

I so move.

.... Discussion, it was put to a vote, and was carried.

Section 49. (See 16)

Report of the Reference Committee on New Business B—Medical Relief, Direct Payment of Medical Fees

DR. MASTERSON: On the resolution presented by Dr. Koplowitz, of the Kings County Medical Society, reading:

"WHEREAS, under the Social Security Act payments for medical care given to recipients-of-aid from the Blind, Old Age, and Dependent Children's divisions of the Department of Social Welfare can no longer be made to physicians directly, but, instead, these payments must be made to the patient; and

"WHEREAS, this method of payment has worked a hardship on the physicians who have rendered medical care to these persons by forcing them to make one or more additional calls to collect their bills; and

"WHEREAS, in New York City it has been proven that nearly 5 per cent of these patients have not paid their doctors for medical care rendered with the money which the State Department of Social Welfare gave them, but instead have spent the money for other uses; and

"WHEREAS, we are informed by the New York City Department of Welfare that this percentage is only a fraction of the number of patients who did not pay their physicians for medical care, as shown by the great many complaints from physicians who have telephoned to that Department, rather than written letters which could be submitted in evidence; and

"WHEREAS, a similar resolution was introduced into the House of Delegates of the Medical Society of the State of New York at Buffalo, in 1941, at which time it was agreed that the State Society would carefully watch the experiment of using this method of payment; and

"WHEREAS, we feel that in New York City this experiment has not been a success; therefore be it

"Resolved, that the New York State Medical Society, through its Delegates to the American Medical Association, request that the American Medical Association have legislation initiated to provide a change in the Social Security Act so that persons rendering medical care to recipients-of-aid from any government agency may be paid directly by that agency,"

your committee recommends the approval of this resolution.

I so move.

.... The motion was seconded.

SPEAKER BAUER: The committee moves the adoption of the resolution. Is there any discussion?

DR. E. CHRISTOPHER WOOD, *Westchester*: Mr. Speaker and Members of the House, in regard to your consideration of this report and this resolution, I would like to bring to your attention the following: It has been the custom for a number of years for this state at least—New York State—to pay physicians directly for their services to medical relief clients, and although the physician is paid directly, that is called the indirect method of payment. Last year, because the Federal Social Security Board was in favor of paying the patient rather than the doctor the money for the services rendered by physicians, this was called the direct payment, and because the Social Security Board insisted that this method be adopted if a state were to be reim-

to record itself as being opposed to this procedure; and to have the Medical Society of the State of New York also request the Department of Welfare to pay those physicians directly, as heretofore; and be it also

"Resolved, that the Medical Society of the State of New York recommend to the American Medical Association to request the Government at Washington to alter that provision of the Social Security Law necessary to permit doctors to be paid directly."

Inasmuch as the matter covered by this resolution is practically the same as that introduced by Dr. Koplowitz, of Kings, we do not feel it is necessary to take any action on the resolution introduced by Dr. Gibbs, Jr., of New York.

SPEAKER BAUER: Inasmuch as the resolution is practically identical, the chair will rule no action is essential on this resolution.

I will ask Dr. Masterson if he would mind deferring the rest of his report until tomorrow morning because there are a number of resolutions that the delegates wish to present, and it would help their consideration considerably if they could be presented this evening so that the reference committees can get them in their hands as soon as possible.

Section 51. (See 68)

Social Security, Physicians

DR. B. M. BERNSTEIN: My resolution concerns social security for physicians when, as, and if social security should so have its base widened as to include many more than it includes at the present time. Even though I am instructed by the Society—

SPEAKER BAUER: Please don't discuss your resolution; you can discuss it all you want to when the reference committee brings it in.

MR. BERNSTEIN: My resolution reads:

"Resolved, that the Delegates of the Medical Society of the State of New York to the American Medical Association be instructed to petition the American Medical Association to study Social Security and methods whereby physicians may participate in its program and benefits."

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business A, of which Dr. Simpson is the chairman.

Section 52. (See 70)

Workmen's Compensation Fee Schedule

DR. RAYMOND F. KIRCHER, Albany: This resolution is from the Medical Society of the County of Albany and concerns the Workmen's Compensation Fee Schedule:

"WHEREAS, the Workmen's Compensation Fee Schedule has been in existence in this State since 1935; and

"WHEREAS, at the time of its adoption many items were generally considered too low; and

"WHEREAS, there has been an increase in the cost of conducting practice due to a general price rise amounting in some necessary items to as much as 35 per cent; therefore be it

"Resolved, that the Delegates from the Medical Society of the County of Albany be instructed to introduce a resolution at the next

meeting of the House of Delegates to the effect that the Council of the Medical Society of the State of New York through its appropriate representatives take immediate steps to review the present fee schedule with the Commissioner of Labor with a view of increasing the minimum fees now established by law (suggested increase 25 per cent), and that the component County Societies be informed from time to time of the status of these proposed negotiations with the Commissioner of Labor."

SPEAKER BAUER: This will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

Section 53.

Constitution and Bylaws—Proposed Amendment

DR. NATHAN B. VAN ETTEN, Past-President: In the interests of promoting a better coordination between the scientific and the administrative functions of the Medical Society of the State of New York, I desire to present an amendment to the Bylaws:

"Be it resolved, that Section 1 of Chapter II of the Bylaws of the Medical Society of the State of New York be amended so as to provide for the inclusion in the membership of the House of Delegates a representative from each scientific section, and that Section 1 of Chapter II of the Bylaws of said Society be amended so as to read as follows:

"Section 1. The House of Delegates shall be composed of (a) Delegates elected by the component County Medical Societies; (b) Officers of the Society and other members of the Council and of the Board of Trustees; (c) the Presidents of the District Branches sitting as District Delegates; and (d) a representative from each Scientific Section to be elected by each such Section. Past-Presidents of the Society shall be life members of the House of Delegates. Each component County Society shall be entitled to elect as many delegates as there shall be State Assembly Districts in such county at the time of the election, but each component County Medical Society shall be entitled to elect at least one delegate. A component Society representing by its name more than one county shall be entitled to as many delegates as there are Assembly Districts in the counties named in the title of such society."

SPEAKER BAUER: This being a proposed amendment to the Bylaws, it must remain in the secretary's hands for one year, when it will be acted on next year after being published at least once.

Section 54. (See 86)

Proposed Subcommittee on Chest Diseases

DR. NELSON W. STROHM, Erie: I wish to introduce the following resolution:

"WHEREAS, at the 1941 meeting of the House of Delegates in Buffalo, New York, a resolution was introduced asking for a session on chest diseases by the New York State Chapter of the American College of Chest Physicians; and

"WHEREAS, the House of Delegates Refer-

Irving just gave you—"because 15 per cent failed to pay their doctor."

SECRETARY IRVING: Five per cent.

PRESIDENT KOPETZKY: "Five per cent failed to pay; therefore, let us scrap our principles and change the method of payment, and permit and endorse the government's paying directly to physicians rendering medical services in the community to underprivileged groups." Here is a test of the sincerity as to whether you practice what you preach.

SPEAKER BAUER: Does anyone else wish to discuss this subject?

DR. PETER MURRAY, *New York*: I should greatly desire to support any movement which would preserve the principles for which we have fought for so long; that is, that there shall be no interposition of a third party between the doctor and the patient, but I am more concerned about being realistic.

Up in my section of the town we do a lot of relief work. If we had to depend on collecting the fees for that relief work from the patient we would be doing all that relief work for nothing. I cannot see the difference between expecting relief clients to pay the doctor and having the Welfare Department send the check on to the doctor, and having the old-age people pay the doctor and having that Department send the check on to the doctor. There has been an interposition between us and those clients already, namely, the municipal authorities or the government authorities. They assign to you cases. They tell you how often you shall see them. They fix your rate of compensation. I think it is little enough to try to guarantee to the members of our profession that after we have accepted these conditions, after we have accepted assignments, after we have accepted a limitation of visits, and after we have accepted a reduction of fees, we should be guaranteed the collection of those fees. I wish to say that if we applied the same parallel to relief clients that we do to all the old age, and expect those people in turn to turn the money over to us, the bottom would fall out of the whole relief situation. It would collapse, and the doctors would either do that work for nothing or would not be paid. I hope we will ask for a return of the direct payment to the doctor in order that we may collect the money we honestly have earned.

DR. HAROLD B. DAVIDSON, *New York*: I would only like to add one point to what Dr. Murray has said, referring to the fact that in having these patients as welfare and relief patients the interposition is already there. Maybe there have only been 5 per cent of the doctors who have written in complaining that they have not received such payment, but that 5 per cent may constitute a very large proportion of the doctors in certain sections of the town. I have heard the complaint that Dr. Murray voiced in the downtown section of New York as well as the uptown section. A great many doctors will not take the time to write letters, but they do constantly make telephone calls complaining about it. Furthermore, a number of them will not take such cases, fearing they will not get paid.

The question of the principle goes further than just the payment of the doctors who do the work. It is a question of whether the interposition of the government, which is there, should be there;

but if it is there, the doctors do deserve payment for the work they do.

DR. HARRY ARANOW, *Bronx*: One of the committees of the Council under the able chairmanship of Dr. Wood has been working on this problem for over a year. It is not an offhand opinion that he gives you, therefore, but a considered one. He has told you that it is almost solved without any special resolutions; therefore, I do not see why this action should be taken.

DR. MASTERSON: May I read one paragraph of this resolution apropos of what Dr. Irving and Dr. Kopetzky have said:

"WHEREAS, in New York City it has been proven that nearly 5 per cent of these patients have not paid their doctors for medical care rendered with the money which the State Department of Social Welfare gave them, but instead have spent the money for other uses, and"

SPEAKER BAUER: The question before you is the adoption of the reference committee's report which recommends adoption of the resolution as drawn. Is there anything else to be said? If not, all those in favor of the reference committee's report, which carries with it the adoption of the resolution, say "Aye," those opposed, "No."

The chair is in doubt. Will those in favor of the committee's report stand; now those opposed?

. . . . All but ten were in favor of the motion. . . .

SPEAKER BAUER: The reference committee's report is adopted, and the resolutions are carried also.

Section 50. (See 19)

Report of Reference Committee on New Business B—Medical Relief, Direct Payment of Medical Fees to the Aged, the Blind, and Dependent Children

DR. MASTERSON: The next resolution is from Dr. William Travis Gibbs, Jr., of New York County. This resolution is about the same as the resolution we just discussed, introduced by Dr. Koplowitz, of Kings, and recommends the same thing:

"WHEREAS, after April 1, 1941, checks from the Department of Welfare of the City of New York (Q. V. Form M. med 383 b) for the medical care of those patients entitled to Old Age Assistance and Blind Assistance will be issued directly to the recipients of the care and not to the doctors rendering it; and

"WHEREAS, this is patently unjust, as it forces the physician to collect these fees from indigent people who may be unreliable; and

"WHEREAS, this is an example of the unfair advantages being taken of physicians; therefore be it

"Resolved, that the Medical Society of the County of New York go on record as being opposed to the proposed change in method of payment; and that the Society request the Department of Welfare to continue its former method of paying these physicians directly; and be it further

"Resolved, that this House of Delegates be instructed to vigorously protest this injustice,

"WHEREAS, an outline of this course has been submitted to and the idea approved by the Comitia Minora and the New York County Medical Society, in view of the fact that the Medical Advisory Board, composed of fourteen members of the New York State Medical Society, competent to direct this work, will have complete supervision of the instruction, to guarantee that those who finish this course shall be qualified, competent masseurs; be it
 "Resolved, that the idea of forming such a medically controlled school be approved by the New York State Medical Society."

SPEAKER BAUER: This will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

Section 58. (See 72)

Basic Science Law

DR. CHARLES GULLO, *Livingston*: The following resolution is introduced by the Livingston County Medical Society to provide a Basic Science Law:

"WHEREAS, there are people in the State of New York practicing the Healing Art without having adequate knowledge of the human body; and

"WHEREAS, experience has shown that it is most difficult and generally futile to effectively prosecute these people even when they have violated the Medical Practice Act; and

"WHEREAS, it is the duty of organized medicine to promulgate medical information and prevent fraudulent and inferior medical service to our people; now, therefore, be it

"Resolved, that the House of Delegates of the New York State Medical Society hereby authorizes and instructs its Legislative Committee to present to the Legislature of the State of New York a suitable bill to correct this condition and that such bill shall provide substantially as follows:

'An Act to provide for examination in the basic sciences, authorizing the Board of Regents to issue a Certificate of Proficiency in the basic sciences, which Certificate shall be a prerequisite to eligibility for examination for license to practice medicine and surgery, osteopathy, osteopathy and surgery, as now prescribed by law, dentistry, or any other system or method of healing that may hereafter be legalized in the State of New York, to define the Basic Sciences, the practice of healing, a license and to provide penalties for the violation of this Act.

'Section 1. Definition as used in this Article:

"Wherever the term, "Practicing Healing," or "Practice of Healing" is used in this Act, unless otherwise specifically defined, the same shall be understood and construed to mean and include any person not herein-after excepted from the provisions of this Act who shall in any manner for any fee, gift, compensation or reward or in expectation thereof, engage in, or hold himself out

to the public as being engaged in the practice of Medicine or Surgery, the practice of Osteopathy, the practice of any legalized method of healing, or the diagnosis, analysis, treatment, adjustment, correction or cure of any disease, injury, defect, deformity, infirmity, ailment or affliction of human beings or any condition or conditions incident to pregnancy or childbirth or examination into the fact, condition or cause of human health or disease or who shall for any fee, gift, compensation or reward or in expectation thereof, suggest, recommend or prescribe any medicine or any form of treatment, correction or cure therefor; also any person or persons, not hereinafter excepted from the provisions of this Act, individually or collectively, who maintains an office for the reception, examination, diagnosis, or treatment of any person for any disease, injury, defect, deformity or infirmity of body or mind, or who attaches the title of Doctor, Physician, Surgeon, Specialist, M.D., M.B., D.O., D.C., or any other word, abbreviation, or title to his name indicating or designed to indicate that he is engaged in the practice of Healing.

'Section 2. Qualifications

'No person shall engage in the "Practice of Healing" unless he shall first have complied with the following prerequisites:

'First: He must pass an examination given by the Board of Regents through its Board of Medical Examiners in the Basic Sciences, namely, Anatomy, Physiology, Physiological Chemistry, Bacteriology, Pathology, and Hygiene, and upon satisfactorily passing such an examination shall receive a Certificate of Proficiency in the Basic Sciences which shall not be interpreted as conferring the right to engage in the Practice of Healing.

'Second: After receiving said Certificate of Proficiency, he must pursue other studies as established by the law and appear before the Board of Choice of the Board of Regents for further examination, and having fulfilled other requirements prescribed by law, he may be licensed to practice.

'Section 3. Exemptions

'All persons already licensed prior to enactment of this Act.

'Section 4. Penalty

'Any person violating any provision or provisions of the foregoing Sections shall be guilty of a misdemeanor punishable by law."

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

If there is nothing further to come before the House at this time, we will stand adjourned until nine o'clock tomorrow morning.

... The session recessed at 6:25 P.M....

ence Committee on New Business gave serious consideration to this resolution by recommending to the House of Delegates that a symposium on chest diseases to be furnished by the New York State Chapter of the American College of Chest Physicians be included at a general session of the Annual Convention in 1942; and

"WHEREAS, the New York State Chapter of the American College of Chest Physicians have respectfully requested that a subcommittee on chest diseases of the Council Committee on Public Health and Education be established; therefore be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York establish such a subcommittee."

SPEAKER BAUER: That will be referred to the Reference Committee on New Business B, of which Dr. Masterson is the chairman.

Section 55

Recognition of Services of Civilian Doctors at Pearl Harbor

DR. CHAS. GORDON HEYD, *Past-President*: I wish to present the following resolution:

"WHEREAS, the civilian physicians and surgeons of the Honolulu Medical Society rendered a great service during the Pearl Harbor Attack on December 7, 1941; and

"WHEREAS, at the outset of the emergency they promptly responded to a call for aid from the Tripler General Hospital of the Army, and by their surgical skill and unremitting efforts rendered great aid to the wounded; and

"WHEREAS, by this service a new chapter was added to the successful treatment of war casualties and certain surgical procedures were established which will result in the saving of many lives and limbs from war injuries; and

"WHEREAS, their service was the more outstanding because only a few of them had ever been under fire, and by their courage and stamina they did much to aid the morale of the wounded, of the hospital personnel, and of the civilian population; and

"WHEREAS, the services of the physicians and surgeons were recognized in the official Roberts Report of the Attack by the statement that 92 per cent of the medical profession were available on that eventful historic occasion; therefore be it

"Resolved, that the Medical Society of the State of New York recognize their response to emergency duty and desires to pay a tribute to their demonstration of the traditional willingness of our profession to act promptly and skillfully in all national emergencies."

DR. HEYD: As this does not involve any policy but is a spreading on the minutes of our appreciation of their services, I move you, sir, that the vote be taken now by the entire delegation of the House of Delegates.

... The motion was seconded. ...

SPEAKER BAUER: This amounts to a suspension of the rules and requires a two-thirds' vote. If there is no objection, however, the motion will be put. Is there any discussion on it?

DR. ABRAHAM KOPLOWITZ, *Kings*: Is there a way of notifying the physicians there? I mean

have they any organization where you can write and tell them about this?

DR. HEYD: If it is passed, it would be transmitted to the Honolulu Medical Society, and I think a copy should go to the respective Navy and War departments

SPEAKER BAUER: Is there any further discussion?

... The question being called for, the motion to adopt the resolution was put to a vote and was unanimously carried. ...

Section 56

Thanks to Director of Selective Service in New York City Area

DR. LAURANCE D. REDWAY, *Westchester*: I have a resolution which reads:

"WHEREAS, Col. Arthur McDermott, the Director of Selective Service in the New York City Area, has consulted the convenience of the medical profession assembled in Annual Convention at the Waldorf Astoria Hotel in the City of New York by establishing a branch of his headquarters for the registration of physicians from out of town who are attending this convention, thus permitting them to register as required by the Selective Service law, while at this hotel; therefore be it

"Resolved, that the House of Delegates of the Medical Society of the State of New York hereby expresses its sincere appreciation for this considerate action on the part of the Director of Selective Service in the New York City Area; and be it further

"Resolved, that this expression of our appreciation be sent to Col. McDermott by the Secretary of the Society."

I move the immediate adoption of this resolution.

DR. ALFRED HELLMAN, *New York*: I will second that.

SPEAKER BAUER: It has been moved and seconded that this resolution be given immediate consideration. Is there any objection? If not, is there any discussion?

... There being no discussion, the motion was put to a vote, and it was unanimously carried. ...

Section 57. (See 71)

Blind Masseurs, Request for Approval of Instruction

DR. MADGE C. L. MCGUINNESS, *New York*: I have a resolution which is as follows:

"WHEREAS, there does not exist, at the present time, any school for the instruction of blind adults in massage and remedial exercise similar to St. Dunstan's in London; and

"WHEREAS, the New York Institute for the Education of the Blind is not permitted to give instruction of any kind to persons over twenty-one years of age, but having facilities, wishes to make them available for adult instruction; and

"WHEREAS, such a course of instruction has been outlined covering about 963 hours, over a period of nine months, it has been proposed to form a school tentatively known as 'The National School for Blind Masseurs,' under the auspices of the National Association of Blind Masseurs. Incorporated, and

"WHEREAS, an outline of this course has been submitted to and the idea approved by the Comitia Minora and the New York County Medical Society, in view of the fact that the Medical Advisory Board, composed of fourteen members of the New York State Medical Society, competent to direct this work, will have complete supervision of the instruction, to guarantee that those who finish this course shall be qualified, competent masseurs; be it

"Resolved, that the idea of forming such a medically controlled school be approved by the New York State Medical Society."

SPEAKER BAUER: This will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

Section 58. (See 72)

Basic Science Law

DR. CHARLES GULLO, *Livingston*: The following resolution is introduced by the Livingston County Medical Society to provide a Basic Science Law:

"WHEREAS, there are people in the State of New York practicing the Healing Art without having adequate knowledge of the human body; and

"WHEREAS, experience has shown that it is most difficult and generally futile to effectively prosecute these people even when they have violated the Medical Practice Act; and

"WHEREAS, it is the duty of organized medicine to promulgate medical information and prevent fraudulent and inferior medical service to our people; now, therefore, be it

"Resolved, that the House of Delegates of the New York State Medical Society hereby authorizes and instructs its Legislative Committee to present to the Legislature of the State of New York a suitable bill to correct this condition and that such bill shall provide substantially as follows:

'An Act to provide for examination in the basic sciences, authorizing the Board of Regents to issue a Certificate of Proficiency in the basic sciences, which Certificate shall be a prerequisite to eligibility for examination for license to practice medicine and surgery, osteopathy, osteopathy and surgery, as now prescribed by law, dentistry, or any other system or method of healing that may hereafter be legalized in the State of New York, to define the Basic Sciences, the practice of healing, a license and to provide penalties for the violation of this Act.

'Section 1. Definition as used in this Article:

'Wherever the term, "Practicing Healing," or "Practice of Healing" is used in this Act, unless otherwise specifically defined, the same shall be understood and construed to mean and include any person not hereinafter excepted from the provisions of this Act who shall in any manner for any fee, gift, compensation or reward or in expectation thereof, engage in, or hold himself out

to the public as being engaged in the practice of Medicine or Surgery, the practice of Osteopathy, the practice of any legalized method of healing, or the diagnosis, analysis, treatment, adjustment, correction or cure of any disease, injury, defect, deformity, infirmity, ailment or affliction of human beings or any condition or conditions incident to pregnancy or childbirth or examination into the fact, condition or cause of human health or disease or who shall for any fee, gift, compensation or reward or in expectation thereof, suggest, recommend or prescribe any medicine or any form of treatment, correction or cure thereof; also any person or persons, not hereinafter excepted from the provisions of this Act, individually or collectively, who maintains an office for the reception, examination, diagnosis, or treatment of any person for any disease, injury, defect, deformity or infirmity of body or mind, or who attaches the title of Doctor, Physician, Surgeon, Specialist, M.D., M.B., D.O., D.C., or any other word, abbreviation, or title to his name indicating or designed to indicate that he is engaged in the practice of Healing.

'Section 2. Qualifications

'No person shall engage in the "Practice of Healing" unless he shall first have complied with the following prerequisites:

'First: He must pass an examination given by the Board of Regents through its Board of Medical Examiners in the Basic Sciences, namely, Anatomy, Physiology, Physiological Chemistry, Bacteriology, Pathology, and Hygiene, and upon satisfactorily passing such an examination shall receive a Certificate of Proficiency in the Basic Sciences which shall not be interpreted as conferring the right to engage in the Practice of Healing.

'Second: After receiving said Certificate of Proficiency, he must pursue other studies as established by the law and appear before the Board of Choice of the Board of Regents for further examination, and having fulfilled other requirements prescribed by law, he may be licensed to practice.

'Section 3. Exemptions

'All persons already licensed prior to enactment of this Act.

'Section 4. Penalty

'Any person violating any provision or provisions of the foregoing Sections shall be guilty of a misdemeanor punishable by law."

SPEAKER BAUER: This resolution will be referred to the Reference Committee on New Business C, of which Dr. Guess is the chairman.

If there is nothing further to come before the House at this time, we will stand adjourned until nine o'clock tomorrow morning.

... The session recessed at 6:25 P.M....

Correspondence

[Continued from page 1142]

"Section 1265, subd. 4 of the Education Law provides:

'... The Chairman of said committee, when charges are preferred, may designate three or more of the members of said committee including at least one member who represents the same school of practice as the physician against whom charges are preferred. ...'

"This provision is outworn and outmoded. The public generally recognizes no fine distinctions between licensed physicians and, in dealing as we are with the statute designed to promote and protect the public health, the profession itself should not persist in perpetuating such classifications and differences. For example, the rights of osteopaths to expand their field of practice have been enacted by the Legislature and regardless of the merits in granting such expansions, it is illustrative of the rapidly fading distinctions between schools of practice, and removes the last valid arguments for making such distinctions.

"Any three members of the Medical Grievance Committee are qualified by ability and integrity to judge the merits of charges against a practitioner of medicine without regard to the school of practice of the physician thus charged or of the members constituting the committee. It is, in a sense, an unintended reflection upon the members of the Grievance Committee to require a member of the same school of practice to sit on a subcommittee. It is my firm belief and contention that the public health would be best promoted

and the practitioner accused of wrongdoing amply protected by removing the requirement that one of the members of the subcommittee be of the same school of practice as the accused.

"Instead of strengthening the statute, the Legislature is weakening it; instead of making it more flexible it has been made unwieldy; instead of simplifying the statute it has been made more complex.

"I respectfully submit that as the bill is unfair, discriminatory, unsound and contrary to the policy of the state, it should not be approved."

In view of the fact that my sentiments on this bill were made clear by Dr. Lawrence, I request that my point of view be published in the State Medical JOURNAL in all fairness and justice to the people and profession of this state.

Very truly yours,

(Signed) VINCENT P. MAZZOLA, M.D.

133 Clinton Street
Brooklyn, New York

NOTE: The Council of the Medical Society of the State of New York received and considered this at its meeting on May 14, 1942. The Council directed publication of the letter together with a statement that the Council approved this legislation and that it had wired the Governor urging him to sign the bill. Since that time the Governor vetoed the bill on the ground that the Board of Regents and the State Department of Education had unanimously opposed it.—Editor

THE CITY OF NEW YORK

EMERGENCY REVENUE DIVISION
50 LAFAYETTE STREET, NEW YORK CITY
WORTH 2-4780

May 25, 1942

To the Editor:

It is called to your attention for the information of the members of your society that the New York City Excise Tax on Gross Receipts imposed under the General Business and Financial Tax Law is due June 15, 1942. The tax is imposed for the privilege of carrying on or exercising for gain or profit within the City of New York any trade, business, profession, vocation, or commercial activity during the period commencing July 1, 1941, and ending June 30, 1942, or any part thereof. The tax is computed upon the gross receipts for the basic period (measuring period) outlined in the law. The basic period may vary according to the circumstances of the taxpayer. The calendar year 1941, however, constitutes the basic period where the taxpayer was engaged in business during the whole of such calendar year.

A physician is required to file a return on Form 42B and report thereon as Item 5 the gross receipts (gross fees) from the practice of his pro-

fession. Interest and dividends received from investments and profits derived from stock and bond transactions should not be included in the return if such transactions are of a personal nature not connected with the doctor's professional activities. In reporting gross receipts, no deduction may be taken for salaries, rent, and other office expenses. This year the tax is to be computed at the rate of $\frac{1}{20}$ of 1 per cent, which is a reduction of 50 per cent of the rate in effect last year.

No tax is imposed when the gross receipts do not exceed \$10,000, and no return need be filed in such cases. There is, however, no specific exemption under the law, and all persons having gross receipts in excess of \$10,000 must report the entire amount thereof.

Returns must be filed on or before June 15, 1942, at the office of the City Collector in the borough in which the taxpayer maintains his office. A remittance for the total amount of tax due, drawn to the order of the City Collector, must accompany the return when filed. Form 42B for filing such returns will be mailed to all taxpayers who have filed returns in prior years. This office will be pleased to furnish further information or assistance in the preparation of returns.

Very truly yours,
GEORGE MARLIN
Special Deputy Comptroller
